LUZULA (WOOD RUSH. Nat. Ord. Juncaceæ).—This is a genus of Rush-like plants not unlike *JUNCUS*, on which we devote a separate short article. They are of very little garden value, but may be used in the moister portions of the wild garden or on stream sides. Numerous species have been described, and nearly a dozen are mentioned in the *Kew Hand-list of Herbaceous Plants.* Of these, *L. Fosteri*, *L. Hostii* (Syn. *L. flavescens*), *L. maxima* (Syn. *L. sylvatica*), and *L. vernalis* (Syn. *L. pilosa*), are fairly well known. *L. campestris*, the CUCKOO GRASS, is probably the best known species of all, but none of these species are plants of much beauty.

LYCASTE.—See *ORCHIDS.*

LYCHNIS (CAMPION, CATCHFLY, etc. Nat. Ord. Caryophyllaceæ).—This genus comprises numerous annual, hardy herbaceous, and rock plants. The annuals are, in our opinion, of little importance compared with the others. Both the Perennial Border Species and the Rock Garden Species may be increased by seeds sown in the usual way in March, or by division in the autumn or spring. They are of easy culture, thriving in good light, ordinary garden loam. The varieties in the first group are splendid for cutting.

Perennial Border Species.—A few of the many desirable sorts are briefly described below:—

Lychnis alba.—This is much better known under its synonymous name *L. vespertina*, under which name we describe it.

L. Bungeana.—An attractive bright scarlet sort, flowering in July and August. Height, 12–15 ins.

L. chalcedonica (JERUSALEM CROSS).—Probably the most popular sort of all. It can be had in white, scarlet, vermilion, red, etc. The flowering period extends from June to September. The double form (*flore pleno*) is splendid. The height varies from 2½–4 ft.

L. coronaria (CROWNED CAMPION).—This is next in popularity to the above. Its range of colours is similar, though it may also be had in attractive rose-pink and reddish-purple forms. It blooms in July and August, averaging about 3 ft. in height. Its variety *oculata* is considered the best.

L. coronata.—Syn. *L. grandiflora*, which see.

L. Flos-cuculi.—This also is a popular sort with a large range of colour, and it is popularly known as RAGGED ROBIN. It blooms in June, continuing into July, and averages about 1½ ft. in height.

L. Flos-jovis (ROSE CAMPION).—By some this is considered a variety of *Lychnis coronaria.* It seems, however, to be distinct enough to rank as a species. It is a bright, rosy-red June and July blooming subject, about 1½ ft. high.

L. fulgens.—An attractive scarlet sort, flowering from June to October, and averaging 12 ins. high.

[1] The PINK LUPINE of some authorities.—EDITOR.

L. grandiflora (Syn. *L. coronata*).—A large, scarlet, free, summer flowering species growing 18 ins. high.

L. haageana.—Another highly attractive scarlet species largely offered by nurserymen, though considered by some synonymous with *L. Bungeana*. It blooms freely in June and July, and its height varies from 1–2 ft.

L. vespertina (Syn. *L. alba*).—This well merits its present popularity, and it can be had in various colours, such as rosy-red, dark crimson, rose, bright pink, and white. It can be had double or single, and blooms freely from early June to late August, and averages rather more than 1½ ft. in height.

L. Viscaria (German Catchfly).—A very useful sort, the colours of which range through pink, red, rose, and white. The flowering period extends from May to August, and the height averages 12 ins. Its varieties *splendens* and *splendens plena* are worthy of special commendation.

Rock Garden Species.—Three species are well worth a place in the rock garden. They are briefly described below, and are propagated by means of seeds sown in spring:—

Lychnis alpina.—A dwarf, tufted plant with narrow leaves. Flowers rose, in dense heads. Site sunny. Soil gritty. It is a biennial, flowering from May to June. Height, 4 ins.

L. Lagascae.—A low-growing plant. Flowers bright rose with white centre. Site, half-shade. Soil gritty. Flowering Period, May to July. Height, 4 ins.

L. pyrenaica.—Similar to the above in character and requirements, but with glaucous leaves, and white flowers which change to rose. The flowers open in May and June. Height, 6 ins.

LYCHNIS LEAF SPOT.—See *Diseases of Rock Plants.*

LYCIUM.—For the best species see *Climbing and Trailing Plants.*

LYCOPERSICUM (Nat. Ord. Solanaceæ).—This is a small genus of half-hardy annuals, only two species of which are at all generally grown in gardens. *L. esculentum* is the well-known Tomato or Love Apple, the culture of which is fully described elsewhere. *L. racemigerum* is the Red Currant Tomato, still somewhat a novelty in this country, but which may be grown in much the same way as tomatoes, and used in a similar manner to red currants.

LYCOPSIS (Nat. Ord. Boraginaceæ).—The Bugloss (*L. arvensis*) is the only well-known species of this little genus. It is an unimportant, weedy, hardy annual, bearing blue flowers from June to August, and averaging 1–2 ft. in height. It cannot be said to be of any garden value.

LYCOPUS (Gipsy Wort. Nat. Ord. Labiatæ).—This is a small genus of hardy, moisture-loving herbaceous perennials which have not yet received much attention. They thrive in ordinary good, rich, wet soil, and may be easily propagated by root division in the autumn, at which time they may be successfully planted. *L. europaeus* and *L. exaltatus* are the two best known species. Both bear white flowers in July, and average 3–6 ft. in height.

LYGEUM (Nat. Ord. Gramineæ). This is an unimportant genus of hardy grasses in this country, but abroad, notably in the Southern Peninsula, it is of great importance for basket work and other similar purposes. Of easy culture, it

thrives in ordinary light, sandy soil, and is easily propagated in the usual way by root division. The best known species is *L. Spartum*, popularly known as CORD GRASS, which grows about 1½ ft. in height.

LYGODICTYON.—Now included in the genus LYGODIUM, for which see *FERNS AND FERN GARDENING.*

LYGODIUM.—For the best species see *FERNS AND FERN GARDENING.*

LYME GRASS.—See *ELYMUS.*

LYSIMACHIA (LOOSESTRIFE. Nat. Ord. Primulaceæ).—A number of hardy annual, biennial, and half-hardy greenhouse species of this genus have been described, but as they are of very little importance, we exclude them from the present work, and confine our attention to the hardy perennial species, the dwarfer forms of which are useful spreading rock plants, while the taller may be effectively planted in the herbaceous, perennial, or mixed borders, in margins to shrubberies, and in the wild garden. Ordinary light soil, in a sunny or lightly shaded spot, suits them, and they may be propagated by division of the root-stocks in October and March, or by seeds sown in the summer in the usual way. Three species previously included are now described under the genus *STEIRONEMA*, which see; thus *Lysimachia ciliata* is now *Steironema ciliatum; L. hybrida* is *S. heterophyllum;* and *L. longifolia* is *S. longifolium.* We cannot describe all the remaining species here, but a few of the best ones are :—

Lysimachia clethroides.—This bears pure white flowers from July to August, on plants 2–3 ft. high.

L. Ephemerum (Syn. *L. salicifolia*).—This bears white flowers in August, and averages 1½ ft. in height.

L. nemorum (YELLOW PIMPERNEL).—This may be used in the rock garden, and bears yellow flowers from June to September, on plants rarely more than 6 ins. high.

L. Nummularia.—This is the well-known CREEPING JENNY, with its yellow flowers in June, a dwarf evergreen plant about 3 ins. high, of which many people are so fond. It is a bit too spreading for the rock garden, but useful in the wild garden or for the less select borders. The variety *aurea* has golden leaves.

L. punctata (Syn. *L. verticillata*).—This is a useful yellow border plant, blooming in July, and growing 1½ ft. in height.

L. quadrifolia.—This is a yellow July blooming sort, about 2 ft. high.

L. salicifolia.—Syn. *L. Ephemerum*, which see.

L. thyrsiflora.—This is a yellow June flowering sort, about 1½ ft. high.

L. verticillata.—Syn. *L. punctata*, which see.

[For FALSE LOOSESTRIFE see notes on *LUDWIGIA.*—EDITOR.]

LYTHRUM (PURPLE LOOSESTRIFE. Nat. Ord. Lythraceæ). — The COMMON PURPLE LOOSESTRIFE (*Lythrum Salicaria*) is a weedy plant of very little value in the garden, but may be used in bog land or at the water's edge. See article on *WATER GARDEN: PLANTS FOR THE.* Its variety *rosea*, however, bearing purple-pink or reddish-pink flowers in July, is more attractive, and may be grown in the herbaceous borders, shrub borders, or wild garden as a hardy perennial. The same remark applies to *L. virgatum*, a purple July blooming sort. Both this and the above grow about 1 yd. in height.

Culture of Lythrums is quite an easy matter. Ordinary soil, plenty of moisture, and a sunny site are

the only essentials to success. Propagation by seeds and division of the roots at the usual times is also easy, and the best time to plant is March.

There are besides the above, several annual species in cultivation, but as they are of comparatively small importance we do not describe them here.

[For FALSE LOOSESTRIFE see notes on *LUDWIGIA*.—EDITOR.]

MACARTNEY ROSE (*Rosa bracteata*). See *ROSE SPECIES*.

MACHAERANTHERA.— Nowincluded in the genus *ASTER*.

MACROSIPHUM. — See under ROSE APHIDES, or GREEN AND RED FLY, in *INSECT PESTS*.

MACROTOMIA (Syn. *Arnebia*. Nat. Ord. Boraginaceæ). — The one species described below is a handsome plant most suitable for the rock garden. It is rarely without flowers, and likes a sunny position in well-drained sandy loam. It is propagated by division of the roots in autumn or spring, also by seeds sown in heat in March.

Macrotomia echioides (PROPHET FLOWER). — This has large leaves in tufts. Flowers soft primrose colour, with five dark purple spots. These fade as the flower becomes older. Flowering Period, April to September. Height, 1 ft.

See also *ARNEBIA*.

MADARIA.—Now included in the genus *MADIA*, which see.

MADAROGLOSSA.—Now included in the genus LAYIA.

MADDER.—See *RUBIA*.

MADEIRA ORCHIS (*Orchis foliosa*).— See *HARDY ORCHIDS*.

MADIA (Nat. Ord. Compositæ). This is a small and not very important genus of annuals which may be treated as hardy or half-hardy. The two best known species are *M. elegans* and *M. sativa* (Syns. *M. stellata* and *M. viscosa*). The latter, popularly known as the MADIA OIL PLANT, is available in two varieties, *congesta* (Syn. *M. capitata*) and *racemosa*. All bear yellow flowers from June to August, and average 1½ ft. in height.

MADIA OIL PLANT.—See *MADIA*.

MADONNA LILY. — See *Lilium candidum* in *LILIES*.

MADROÑO (*Arbutus Menziesii*).—See *SHRUBS*.

MADWORT.—A name applied to the genus *ALYSSUM*, which see.

MAGNESIA AND MAGNESIUM COMPOUNDS. — Attention may well be drawn to a few of the compounds of Magnesia even though their use in the garden is somewhat limited. The metal itself finds no horticultural application, but its salts, the Carbonates, Chloride, Hydroxide, and Oxide are used, though to a limited extent, for application to soils which are too hot, and generally may be regarded as having cooling properties. Magnesium Carbonate in its simplest form is at times offered as a rock for wall garden building under the name of MAGNESITE, or as a double carbonate with lime under the name of DOLOMITE, but both these rocks are unsuitable. Magnesium Chloride is found with common salt in KAINIT. Magnesium Oxide is prepared by burning Magnesite, just as Calcium Oxide or Quicklime is obtained by burning limestone. The Hydroxide is not, however, prepared by adding water to the oxide, but by adding a hydroxide of another metal to a solution of some compound of Magnesia. The gardener frequently uses asbestos for lining the hot-water pipes of his greenhouse, and, if he is a smoker, he may use a meerschaum pipe. These are both compounds of Magnesia.

A compound of Magnesia that may have a future before it, if it can be prepared cheaply enough, is Magnesium Nitride, which slowly gives off ammonia in contact with

water. It may supersede CALCIUM CYANAMIDE (see article on *LIME COMPOUNDS*) in this connection on hot, dry soils. It can be prepared by heating Magnesium with Nitrogen or Ammonia, but at present it is little more than a chemical curiosity.

Little is known horticulturally of the uses of Magnesium Nitrate, Phosphate, Pyrophosphate, and Sulphide. The use of these does not appear to have got beyond the experimental stage.

The most important compound from the gardener's point of view is MAGNESIUM SULPHATE. — This the gardener or his family will probably have taken many times as an aperient under its well-known name of EPSOM SALTS, but the crude compound is very useful as a manure, especially for roses. Applied at the rate of 1 oz. per sq. yd. in the spring, it proves distinctly advantageous, and it is well to note that the carbonate can be used in the same manner, though at double the rate. Magnesium Sulphate is also used as an ingredient of *TONK'S MANURE*, to the article on which our readers are referred.

E. T. E.

MAGNESITE.—See above article.

MAGNESIUM COMPOUNDS. — See *MAGNESIA AND MAGNESIUM COMPOUNDS*.

MAGNOLIA.—For the best species see *CLIMBING AND TRAILING PLANTS*, *SHRUBS*, and *TREES*.

MAGPIE MOTH.—See *INSECT PESTS*.

MAHARANGA.—Now included in the genus *ONOSMA*.

MAHONIA (*Berberis Aquifolium*).—See *SHRUBS*.

MAIDEN PINK (*Dianthus deltoides*). See *DIANTHUS*.

MAIDENHAIR FERN (*Adiantum Capillus-Veneris*).—See *FERNS AND FERN GARDENING*.

MAIDENHAIR TREE (*Ginkgo biloba*). See *TREES*.

MAINCROP CELERY.—See *CELERY*.

MAIZE, or INDIAN SUGAR CORN (*Zea Mays*. Nat. Ord. Gramineæ). —This vegetable has rapidly come to the fore during recent years, and can be strongly recommended to those who find many of the more popular summer and autumn vegetables not to their liking.

Culture.—Sow the seed in a warm greenhouse during April or early May. Single pots are the best, as from these the plants may, without any check to growth, be put into their summer quarters, choosing a piece of well-manured ground, and keeping well supplied with water. The cobs or fruits are ready for cooking just as the hairy-like substance around them begins to turn brown. Allow from 1–2 ft. apart in the rows.

Varieties.—The best for home cultivation include: Early Sweet Cory, Early Sweet Minnesota, Extra Early Premo, and Kendall's Giant.

F. R. C.

MALCHOMIA or **MALCOLMIA.**—The same as *MALCOMIA*.

MALCOMIA.—See *VIRGINIAN STOCK*.

MALE FERN. — See under FERN (MALE) in *MEDICINAL HERBS*.

MALE FERN (*Nephrodium Filix-mas*). See *FERNS AND FERN GARDENING*.

MALLOW.—See *MALVA* and *MEDICINAL HERBS*.

MALMAISON CARNATION.— See *CARNATION: THE MALMAISON*.

MALOPE (Nat. Ord. Malvaceæ). This genus is closely allied to *LAVATERA* and *MALVA* (which see), and one of its members, popularly known as *M. grandiflora*, if treated as a hardy or half-hardy annual, is a capital town plant. It is capable of being grown into a large specimen 2 ft. high, which, when covered with its large, satiny flowers, is most effective. It may be success-

fully raised by sowing seeds in a greenhouse in early March, or in the open ground in April. In the latter case thinning out the plants to 18 ins. apart is advisable. If raised under glass, the seedlings should be potted singly while quite small, and planted out in May not less than 18 ins. apart, as they have a very bushy habit of growth.

Malope trifida (Syns. *M. ciliata* and *M. grandiflora*).—The type is rarely grown, as the grandiflora strains are finer. There are white, rose, and red-coloured varieties, all of which come fairly true from seeds, and bloom from June to October.—C. H. C.

MALT DUST.

This is not of any great value for the land, but may be dug in at the spring of the year in a fresh state at the rate of 1–3 cwt. per sq. rod, according to whether the soil is poor or rich in humus.

MALVA (Mallow. Nat. Ord. Malvaceæ).—A number of the Mallows are popular in British gardens, but this can scarcely be said of the annual species. Of these latter probably not more than two are well known, and only one is generally grown. This (*M. crispa*) is more valued as a foliage plant in connection with sub-tropical effects than as a flowering plant, and grows about 5 ft. high.

The Annual Mallows may be raised from seeds sown under glass in gentle heat in March, and at a very early date the seedlings should be potted singly in light rich soil. When the pots are fairly well filled with roots they should be stood in a frame to harden off gradually prior to being planted out at the end of May or early in June. Seedlings of *M. crispa* should be potted a second or even a third time, if necessary, so as to encourage robust growth. They need abundance of water in dry weather.

Perennial Border Species.—These are somewhat numerous and are useful plants for the border, with the exception of *M. sylvestris*, which is more useful in the wild or water garden. All are of easy culture, and no particular remarks are necessary here. They may be raised from seed sown in the usual way in the summer, or they can be propagated by root division in the autumn or spring, at which time they may be successfully planted. We recommend the following species :—

Malva Alcea (Syn. *M. alceoides*).—This, the Vervain Mallow, and its variety *fastigiata* (Syn. *M. Morenii*) bear rose-pink and clear, red flowers respectively from July onwards, and grow 2–4 ft. in height.

M. moschata (Musk Mallow).—This is a favourite garden plant bearing pretty pale rose-pink flowers from June onwards, and averaging 1½–2 ft. high. Its variety *alba* is pure white.

M. sylvestris.—This is the true Marsh Mallow useful in medicine. See under Mallow in our article on *Medicinal Herbs*. As already mentioned, it may be grown in the wild or water garden, where it will bear purple flowers from May to October, on plants 2–4 ft. in height.

[The greenhouse perennial and greenhouse shrub sections of this genus are omitted, as being of little importance. Many of the latter, as well as the hardy species, are now included in the genus *Malvastrum*, on which a separate article appears. To describe the stove sections with their culture is beyond our present scope.—Editor.]

MALVASTRUM (False Mallow. Nat. Ord. Malvaceæ).—This genus used to be included in *Malva*, but is now considered distinct. It

contains some useful greenhouse evergreen shrubs and hardy herbaceous perennials.

Greenhouse Species.—These are very free flowering evergreen shrubs, which remain in flower for a long period during the summer months, and require only ordinary greenhouse treatment if potted in a compost of good fibry loam, peat, and silver sand. Cuttings inserted in sandy soil under bell-glass or frame in a little heat prove the best means of propagation. Temperature required, 40–50° F.

Malvastrum asperrimum.—Red. Flowers in July. Height, 3 ft.

M. grossulariæfolium.—Rose. Flowers from July to August. Height, 2 ft.

M. hypomadarum.—Pale rose. Flowers from July to August. Height, 2 ft.

M. tridactylites.—Pink. Flowers from July to August. Height, 3 ft.

Perennial Border Species.—The five species described below are all splendid hardy perennials useful for the borders or rock garden, except the last, which requires the treatment usually given to biennials. They will succeed in good, light, rich soil in a sunny site, and may be propagated in the usual way by seeds sown in the spring or summer and by division of the rootstocks in March, which last is the best period for planting.

Malvastrum coccineum.—This is a scarlet sort, blooming from June to July, and growing about 6 ins. high.

M. Gilliesii.—This is a bright red or scarlet species, blooming from June to August, and growing the same height as the above. It is not hardy in the north.

M. lateritium.—This is a bright vermilion-red sort, blooming from August to September, also 6 ins. high.

M. limense.—This is a pretty pink species, blooming freely from June to September, and growing about 12 ins. high.

M. tricuspidatum.—This is a useful yellow biennial species, blooming onwards from July, and growing 12 ins. high.

MAMESTRA.—See CABBAGE MOTH in *INSECT PESTS.*

MAMILLARIA.—A genus of cactaceous plants. See *CACTI.*

MAMMOTH GOURD.—See *ORNAMENTAL GOURDS.*

MAMMOTH TREE (*Sequoia gigantea*). See *TREES.*

MANAGEMENT OF ALLOTMENTS.—See *ALLOTMENTS: MANAGEMENT OF.*

MANAGEMENT OF CORDONS.—See *CORDON FRUIT TREES.* See also *ROOT PRUNING.*

MANAGEMENT OF GREENHOUSES. See *GREENHOUSE: MANAGEMENT OF.*

MANAGEMENT OF ROCK GARDEN.—See *ROCK GARDEN: MANAGEMENT OF.*

MANAGEMENT OF SEEDLINGS.—See *SEEDLINGS: MANAGEMENT OF.*

MANDRAGORA.—See *MANDRAKE.*

MANDRAKE (*Mandragora.* Nat. Ord. Solanaceæ).—As a medicinal plant Mandrake has now fallen into little use, and in gardens there is little call for its culture unless the collection be very extensive. Botanically it is a very hardy herbaceous perennial with long fleshy roots, and is best propagated in the summer by seeds sown in the usual way. *Mandragora autumnalis* and *M. officinarum* (Syn. *M. vernalis*) are the two best species, and the last is the MEDICINAL MANDRAKE proper. The first, as its name implies, flowers in the autumn (September), while the other blooms in April. Both bear light sky-blue flowers, and average 6 ins. in height.

MANDSCHURIAN CRAB (*Pyrus niedzwetzkyana*).—See *TREES.*

MANNA ASH (*Fraxinus Ornus*).—See *TREES.*

MANNA GRASS.—See *GLYCERIA.*

MANSAK (*Hamamelis arborea*).—See *SHRUBS.*

MANURE AND FRUIT TREES.—See *FRUIT CULTURE, HARDY.*

MANURE TOP-DRESSINGS.— See *TOP-DRESSING.*

MANURES.

The purpose of applying manure to the soil is threefold: to improve the tilth, to raise the temperature, and to increase the supply of available plant foods. All manures, including the light, so-called "artificials," effect the last-mentioned object in greater or less degree; only bulky organic substances such as dung have any perceptible effect on the tilth or temperature. The latter are therefore of greater importance to the gardener. For him the tilth is the *sine qua non*, and, for certain purposes, temperature is scarcely less important. For these reasons gardeners do not hesitate to apply four or five times as much manure as farmers would use in similar circumstances.

Farmyard manure or dung (see also separate article) contains all necessary kinds of plant food, but when it is used in considerable quantity it should be supplemented by a fairly liberal allowance of superphosphate or basic slag, in order to correct a tendency to rankness of growth in vegetables, and to improve the yield and quality of fruit and flowers. Given unlimited supplies of dung and phosphates, as a rule nothing else is required, and it is only in special circumstances that artificials can be profitably employed. The supply of good farmyard manure is, however, rapidly diminishing owing to the replacement of horses by mechanical traction, and cow dung from town dairies is often cold and poor. It is probable that in future gardeners will have to depend more and more upon leaf-mould, ferns, peat moss, spent hops, and green manuring to maintain the supply of humus, without which tilth, as gardeners understand that term, cannot be produced; but even when composted (mixed with earth and lime and saturated with liquid manure to promote fermentation) these are mild manures, since they contain but little available plant food, and artificial manures must be added to make good the defect. To be effective the artificials must be adapted to the requirements of the soil, and to the requirements of the crops to which they are applied.

In general, the fertilising ingredients of organic manures, *e.g.* bones, fish and meat meals, guanos, etc., are insoluble, and only become available to plants as the substance decomposes in the soil. Such manures, therefore, act best on the lighter soils, and they are the more suitable because they are less liable to loss by drainage than the more soluble products such as sulphate of ammonia. The latter act more rapidly, and on stiff soils the risk of loss is less. Apart from these considerations a manure may be said to be adapted to the requirements of the soil when it supplies ingredients of which there is a deficiency absolute or relative. Nearly all soils are more or less deficient in phosphates. Sandy soils and peaty soils are commonly deficient in potash, whereas clay soils are usually well supplied with that ingredient. These questions, however, can only be determined by experiment, and it is advisable to try the effect of potash and phosphatic manures together as well as separately, roots, such as swedes, being the most suitable kind of crop for the purpose.

Crop Requirements. — The requirements of crops depend upon (1) the total amount of plant foods

they absorb; (2) their assimilative capacity; and (3) the time of year at which they are grown. Plants of the same kind are as a rule much alike in these respects, and may be arranged in groups accordingly. Thus we may say in general that :—

ROOTS, such as beet, carrots, parsnips, radishes, salsafy, and turnips require chiefly phosphates, with a fairly liberal amount of potash and little or no nitrogenous manure.

SEED CROPS, or flowers, fruits, and vegetables of which the seed case or seed is the part required, as is the case in such as beans, cucumbers, marrows, melons, peas, and tomatoes, require liberal amounts of both phosphates and potash, and only small amounts of nitrogenous manures.

STEM AND LEAF CROPS, such as asparagus, cabbages, celery, lettuces, parsley, rhubarb, and spinach, require chiefly nitrogenous manures, with a fairly liberal amount of phosphates, and but little potash.

TUBERS, such as artichokes and potatoes, and LEAF-BULBS, such as leeks, onions, and shallots, require chiefly potash, with a moderate amount of phosphates, and only small amounts of nitrogenous manure.

It is to be noted that the more readily soluble nitrogenous manures tend to produce rather rank growth, and should therefore be used somewhat sparingly for the more delicate plants, especially such as celery and lettuces, which require to be blanched. Quality is generally more profitable than quantity. In fact for nearly all garden crops, except, perhaps, cabbages and spinach, the more slowly acting nitrogenous manures (*q.v.*) are as a rule to be preferred. On the other hand, the more readily soluble kinds if applied to apples, plums, etc., after the fruit is formed and is beginning to swell, often produce splendid results.

Classes of Manures.—Manures may be classified as (1) GENERAL MANURES, *i.e.* those which contain appreciable amounts of all three fertilising ingredients — nitrogen, phosphates, and potash; and (2) SPECIAL MANURES, *i.e.* those which contain only one or at most two fertilising ingredients of which one predominates. The former includes all the bulky organic manures which supply humus and tend to improve tilth; it also includes a few which contain little or no humus. The latter class comprises all, or nearly all, the so-called artificial manures or fertilisers. Both may be divided into sub-groups as follows :—

GENERAL MANURES.

(1) ANIMAL, *e.g.* dung, liquid manure, sewage, etc. See articles on *COW MANURE*, *FEEDING PLANTS*, *HORSE MANURE*, *PIG MANURE*, *SEWAGE AS MANURE*, *SHEEP MANURE*, etc.

(2) VEGETABLE, *e.g.* leaf-mould, peat, seaweed, etc. See articles on *LEAVES*, *PEAT*, *SEAWEED AS MANURE*, *VEGETABLE MATTER*, etc.

(3) MIXED PRODUCTS, *e.g.* manure and loam, manure and seaweed, etc. See articles on *COMPOSTS*, *FARMYARD MANURE*, *SEAWEED AS MANURE*, etc.

SPECIAL MANURES.

(1) PHOSPHATIC, *e.g.* basic slag, superphosphate, etc.

(2) PHOSPHO-NITROGENOUS, *e.g.* bones, fish meals, etc.

(3) NITROGENOUS, *e.g.* meat meal, nitrate of soda, sulphate of ammonia, etc.

(4) POTASH, *e.g.* kainit, sulphate of potash, wood ashes, etc.

(5) COMPOUND FERTILISERS, of which there are now many makes.

(6) GUANOS of every kind.

(7) Miscellaneous Manurial Substances, *e.g.* copperas, gypsum, etc.

Notes on Special Manures.

The following notes on the various kinds of special manures are arranged under the above heads. See also articles on *Ammonia and Ammonium Compounds; Iron and Iron Compounds; Magnesia and Magnesium Compounds; Lime Compounds; Potash and Potassium Compounds; Soda and Sodium Compounds*, etc.

(I) **Phosphatic Manures.** — The following are the most important :—

BASIC SLAG.—This is a by-product in the manufacture of steel: average qualities contain from 25–35% of total phosphates, the normal price being £2–3 per ton, according to quality. The phosphates in basic slag are insoluble in water, but, being basic in character, become available for plants more readily than those of the Raw Phosphates mentioned below. From 20% to 90% of the total phosphates of basic slag may be soluble in a 2% solution of citric acid (Wagner's method), but recent experiments tend to show that samples which have a high "citric solubility" are not necessarily superior, as was formerly believed to be the case. The manurial efficiency of basic slag appears to depend to a much larger extent upon the fineness of grinding, and, next to the percentage of phosphates, that is the most important consideration. The guarantee commonly given is that at least 80% of the powder will pass through a sieve having 100 wires to the inch, *i.e.* 10,000 holes to the square inch; less finely ground samples should not be purchased even if offered at lower prices. It is often asserted that basic slag contains free lime, but the amount of that ingredient in samples produced by more modern methods is usually insignificant; the presence of even small amounts, however, serves to emphasise the basic character of this manure as opposed to the acid character of superphosphate, and on this account it is preferable for root crops and leguminous plants when the soils are deficient in lime. Basic slag does not act well on dry soils; for this reason, and also because it tends to flocculate clay and so to improve tilth, it generally shows to greater advantage on stiff soils. It should be applied at the rate of 4–8 oz. per sq. yd.

BASIC SUPERPHOSPHATE.—This, made by mixing ordinary superphosphate with lime, has been recommended for light soils deficient in lime, but better results would probably be obtained by first dressing the soil with ground chalk and then applying ordinary superphosphate. If used, however, it should be applied at the rate of 2–3 oz. per sq. yd.

RAW PHOSPHATES. — These include mineral phosphates (apatites and phosphorites), phosphatic guanos, coprolites, etc., which have not been chemically treated. If very finely ground they are not without effect, but act slowly and are not profitable. They are rarely offered in retail.

SUPERPHOSPHATE.—This is made by heating raw phosphates or bones with sulphuric acid (oil of vitriol); average qualities containing 25–35% of phosphates soluble in water; the normal price of which is £2, 10s. to £3, 10s. per ton according to quality. It is one of the best garden manures, suitable for nearly all crops, but, being acid, should not be used on soils deficient in lime. If stored in damp places the phosphate is liable to revert

to the insoluble state, and the efficiency of the manure is reduced. Apply 2–3 oz. per sq. yd. in the spring before sowing, or 1 oz. per gallon of water in the summer.

(II) **Phospho-Nitrogenous Manures.**—The most important are :—

BONES.—After extraction of the fat, the bones are crushed and sifted ; the portion which passes through sieves having two wires to the inch is called "half-inch bones," and that which passes through sieves having four wires to the inch is called "quarter-inch bones." These act very slowly and are unsuitable for ordinary purposes. Of the finer portion, known usually as bone-meal, or as bone-dust and bone-flour, at least 90% should pass through a sieve having eight wires to the inch, and if it be more finely ground so much the better. A more or less considerable portion of the nitrogenous matter (gelatine) is sometimes removed by steaming and the residue is known as steamed bone-flour : this product necessarily contains a higher percentage of phosphates than unsteamed bonemeal, but owing to the removal of nitrogen it is of different manurial value and is cheaper. Finely ground bonemeal and steamed bone-flour are very suitable for all the more delicate garden crops, but are rather slow for the stronger vegetables. To use, apply about 2 oz. per sq. yd. at the back end of the year or early spring, and lightly fork in. See also separate article on *Bones*.

Dissolved or Vitriolated Bones.—These are made by treating half- or quarter-inch bones with sulphuric acid. The material is sometimes called "bone superphosphate," but the term is ambiguous and misleading. By the action of the acid some of the phosphate is rendered soluble in water, and the nitrogenous matter is also altered and becomes more readily available to plants. Average samples contain 10–15% of soluble phosphates, as well as 15–20% of insoluble phosphates and 2–3% of nitrogen, the normal price being about £7–8 per ton. It forms an excellent manure safe and suitable for nearly all garden crops, but, being acid, should not be applied to soil deficient in lime. It acts more rapidly than bonemeal, but is more expensive in proportion to the amount of fertilising ingredients it contains, and is best used at the rate of 1–2 oz. per sq. yd. in the spring. For methods of dissolving bones see Dissolved Bones in article on *Bones*.

FISH AND MEAT MEALS.—These products are often described as "guanos," but they are not excrements : the former is made from dried fish offal from the curing stations ; the latter is made of slaughter-house refuse, condemned carcasses, and to some extent also from the residues obtained in the manufacture of meat extracts. Both fish and meat meals contain high percentage of nitrogen, and some samples also contain considerable amounts of phosphates. The percentage of the latter ingredient depends mainly upon the amount of bone included. In some samples bone is almost entirely lacking, and these should not be classed as phospho-nitrogenous but as purely nitrogenous manures. The fertilising ingredients are insoluble, but become available to plants as the substance decomposes : on light soils this occurs fairly rapidly, and the manures are perhaps more suitable for fairly hardy vegetables. For ordinary garden purposes apply about 1 oz. per sq. yd. in early spring and lightly fork in, but if used for flowers or fruit about half that quantity will be enough.

(III) **Nitrogenous Manures.** — These form a very large class. Some of the most important are described below :—

NITRATE OF LIME.—This is manufactured from the nitrogen of the air by a recently discovered process, and averages about 75% pure, or, in other words, contains 13% of nitrogen. The remainder consists mainly of lime, and for this reason it is sometimes recommended in preference to nitrate of soda, which in some respects it closely resembles, but it is more expensive in proportion to the nitrogen it contains. The normal price is £9–10 per ton, but large quantities should never be bought as it attracts moisture strongly, and thus becomes spoilt. For use apply ½–1 oz. per sq. yd.

NITRATE OF POTASH.—This is commonly known as SALTPETRE, and the pure salt contains 14% of nitrogen, with 46·5% of potash. It is very similar to nitrate of soda and is sometimes recommended for garden use, but is not economical. Apply 1 oz. per sq. yd.

NITRATE OF SODA.—This is a natural product imported from Chile, average samples being 95% pure. The material contains 15·6% of nitrogen, and its normal price is £10–12 per ton. It is extremely soluble in water and too rapid in action for most garden crops except strong green vegetables, such as cabbages. It should not be allowed to come in contact with leaves as it is liable to burn them. The notion that this manure exhausts the soil may be dismissed, so long as lime has been applied first. For use scatter 1 oz. per sq. yd. and hoe or water in.

NITROLIM.—This is manufactured from nitrogen of the air, and contains about 60% of calcium cyanamide, or 20·6% of nitrogen, *i.e.* about the same as sulphate of ammonia ; it also contains about 25% of quicklime and 15% of other harmless impurities. It is known also as CYANAMIDE, and is suitable for the same crops as sulphate of ammonia, but is much better on soils deficient in lime. Apply ½–1 oz. per sq. yd. in the spring about a fortnight before seed sowing.

ORGANIC PRODUCTS.—This group includes various kinds of scrap and refuse material of animal origin. In general character they all resemble those fish and meat meals which contain no phosphates but are purely nitrogenous manures. The nitrogen is insoluble and only becomes available as the substances decompose in the soil, and the materials vary considerably in composition as well as in rate of action. Most of them are difficult to obtain in retail quantities.

DRIED BLOOD.—This is perhaps one of the most important members of the group, but is more rapid in its action than any of the others, and is a suitable nitrogenous manure for the majority of garden crops. Average samples contain 12–14% of nitrogen, the normal price of the material being £8–9 per ton. For use apply ½–¾ oz. per sq. yd. in the spring, and lightly fork in.

HOOF PARINGS, horn shavings, ivory dust, and leather dust may yield as much as 16% of nitrogen, but samples sold as manure usually contain less—only about half that amount very often. In the untreated condition their action is extremely slow and their purchase is not recommended.

WASTE HAIR, feathers, shoddy, and woollen rags are similar in composition and properties to hoof parings, etc., but they are not quite so slow in action and are used to some extent as garden

manures, chiefly for flower-beds, fruits, and roots. They may be made into a compost by mixing with earth and lime, and the heaps saturated with liquid manure to promote fermentation.

SULPHATE OF AMMONIA.—This is a by-product from gas works, and average samples are 95% pure, these containing 24·5% of ammonia or 20% of nitrogen, the normal price being £13–16 per ton. It is readily soluble in water and acts rapidly, but is safe enough for hardy vegetables, for backward crops and for late applications in quantities not exceeding ½–1 oz. per sq. yd; it should not be applied before the seed, but only to growing crops. To secure the best results the total quantity should be mixed with two or three times its weight of sand or gypsum and the mixture divided into three equal portions, to be applied at an interval of a week or ten days. For delicate plants, *e.g.* flowers, this precaution should always be observed. The manure is not acid, but may give bad results on soil deficient in lime.

(IV) **Potash Manures.** — These form a very important class. The chief are briefly described below :—,

ASHES.—The ash of all plants *e.g.* weeds, straw, wood, etc., contains 10–35% potash, which is present chiefly in the form of the carbonate. As this is an alkaline salt, it has an injurious action on seeds and roots, and tends to spoil the the tilth of clay soils. Thus ashes should not be too freely used. The amount produced in the ordinary course of garden operations is, however, too small to do any harm, and larger quantities are not as a rule obtainable. The common belief that coal ashes are injurious is mistaken; cinders, of course, are objectionable, but coal ashes finely ground and sifted through a one-eighth inch sieve are nearly as good as wood ashes. Twigs, hedge trimmings, prunings from fruit trees, and other similar material contain more potash than older timber, while grass and weeds are also rich in that ingredient. It is sometimes recommended that these should not be burned but allowed to rot so as to avoid losing the nitrogen they contain, but this loss is a small matter compared with the importance of destroying running roots and the seeds of noxious weeds. See also articles on *Ashes* and *Burning Garden Rubbish*.

FLUE DUST.—This is obtained from iron furnaces, and contains from 3–12% of potash, and costs £2–5 per ton; it is insoluble and cannot be expected to produce such good effects as the German salts mentioned below, but is now being tried as a substitute while these are unobtainable, and in some cases has been very successful. For use apply 3–4 lb. per sq. rod.

KAINIT.—This is obtained from natural deposits at Stassfurt in Germany; it may be regarded as a mixture of sulphate of potash with common salt and some magnesium compounds; the last are of no value, and common salt is positively injurious to most garden crops, including potatoes. Kainit usually contains 10–12% of potash, and four or five times as much must therefore be used to produce the same effect as 1 lb. of sulphate or muriate of potash. The normal price is about £2 per ton, but for equal amounts of potash it is no cheaper than the others. Kainit cannot therefore be recommended except perhaps for asparagus and such other plants as are known to withstand or benefit by the effects of large amounts of common salt. For use apply it at the rate of 2–4 oz. per sq. yd. in the autumn or winter.

MURIATE OF POTASH.—This also is obtained from Germany, average samples being about 80% pure, and thus contain 50·5% of potash. In other respects it is practically the same as sulphate of potash and may be used in the same way, but the latter is perhaps to be preferred.

SULPHATE OF POTASH. — This is also obtained from Germany, average samples being about 90% pure, and thus contain 48·6% of potash, the normal price being £8–9 per ton. The potash is soluble in water, but is retained by the soil and not therefore liable to loss. This is the best potash manure for flowers, fruits, potatoes, and most other garden crops, and for equal amounts of potash it is not more expensive than any other. For use apply about 1 oz. per sq. yd. in the spring before sowing seeds.

(V) **Compound Fertilisers.** — Products prepared from scrap and refuse material chemically treated to render the manurial ingredients more readily available to plants and sometimes mixed with simple fertilisers are classed as compound fertilisers or manures. Most of them contain phosphates and nitrogen, some also containing potash. In many cases the ingredients are blended in the proportions supposed to be suitable for particular crops, and these are generally described as "potato manures," "vine manures," "fruit and flower manures," and so on. In other cases the manures are represented as being more or less suitable for all crops, and these are usually described by some personal or purely fancy name, *e.g.* "Smith and Jones' manure," etc. Some of these so-called compound fertilisers or manures are quite worthless, but this form of fraud is fortunately not so common now as formerly, and those sold by reputable firms usually contain the amounts of fertilising ingredients advertised and guaranteed. In view of the comparatively small amounts of fertilisers commonly used by gardeners such mixed or compound manures have much to recommend them for horticultural purposes, and the objection to applying nitrogen at the same time as the phosphates and potash loses much of its force if the nitrogenous matter is of a slow-acting character, as it should be in garden manures. It cannot be said, however, that compound fertilisers or manures are economical; equal quantities of nitrogen, phosphates, and potash can always be obtained at less cost in the form of simple fertilisers; allowing for the cost of treatment, mixing, and the fact that they are sold to gardeners in relatively small quantities, the prices charged for some compound manures are undeniably excessive.

Dissolved bone compounds, for example, should not be charged for at the same rate as vitriolated bones, even if they contain the same percentages of fertilising ingredients, because such compounds may consist mainly of a mixture of superphosphate, sulphate of ammonia, and scrap materials that can be obtained at much lower prices than bones. The name is deceptive, and unless such a compound is offered at a much lower price, gardeners would be well advised to purchase pure dissolved bones (*q.v.*) or to choose some other manure.

MIXING MANURES.—It is a mistake to imagine that mixed or compound fertilisers or manures can be made without a good knowledge of chemistry. Almost all kinds of manure may be applied to the same piece of soil; but they should not be first mixed together, as some of them react, mutually destroying

their peculiar properties or causing loss of fertilising ingredients, and in certain cases damage to persons and property as well. Mixing never does any good: it often does much harm. In any case different kinds of manure should not as a rule be applied at the same time of year. For particular fertilisers not to mix see our article on *Artificial Fertilisers*.

(VI) **Guanos.**—See separate article.

(VII) **Miscellaneous Manurial Substances.**—Common salt, copperas, and gypsum are used by some gardeners, but they contain no fertilising ingredients and are not, strictly, manures at all. Gypsum is merely a make-weight, and, in quantity, the other two may be more or less injurious to most garden crops.

Valuation of Manures. — The "normal prices" quoted in this article are intended merely to convey some idea of the relative cost of the different substances: they are, roughly, those prevailing prior to 1914. There is no necessary connection between the prices and productive efficiency. The latter depends mainly upon the percentages of fertilising ingredients present: the former fluctuate from day to day from independent causes. For purposes of valuation, however, it is assumed that, while conditions—as regards supply and demand—remain the same, the price is, or should be, proportional to the percentages of fertilising ingredients. For example, if superphosphate containing 25% of soluble phosphates can be purchased at £2, 10s. per ton, the price of superphosphate of any other grade may be found by "rule of three" as follows:

25% super. costs . 50s. per ton.
1% " " . $\frac{50}{25}$ = 2s. per ton.
35% " " 2s. × 35 = 70s. per ton.

The price per ton divided by the percentage of fertilising ingredient is called the unit value of that ingredient. Prior to 1914 these were approximately as follows:

	Per unit. s. d.
Insoluble phosphate (in basic slag)	1 3
Soluble phosphate (in superphosphate)	2 0
Potash (in sulphate or muriate of potash)	3 6
Nitrogen (in sulphate of ammonia)	12s. to 14s.

The unit value of any ingredient is not necessarily, or usually, the same in different kinds of manure, but the ratios of the unit values of the several ingredients is nearly the same in all; and it is by preserving these ratios that the unit values of the several constituents in manures that contain more than one can be determined in accordance with the current prices. In bones the unit value of nitrogen is higher than in sulphate of ammonia, and the unit value of the phosphates is higher than in basic slag. This does not mean that bones are better manure, but only that they are more expensive.

The unit values of the fertilising ingredients in various manures are published periodically in the technical press, and may be used to calculate the price per ton. The rule is: "Multiply the price per unit of each constituent by the percentage present," and the sum of the products gives the price per ton. Take as an example a mixed manure and let the data be as follows:

Fertilising Ingredient.	Value per unit. s. d.	Percentage present.	Value per ton. s. d.
Nitrogen	15 0	× 7·2	= 108 0
Soluble phosphate	2 1	× 16·5	= 34 4
Insoluble phosphate	1 4	× 12·4	= 16 6
Potash	3 8	× 6·8	= 24 11
Total			183 9

Price per ton = $\frac{183\frac{9}{12}}{20}$ = £9, 3s. 9d. per ton.

The price of any manure, *e.g.* superphosphate, may be different at London, Hull, Bristol, etc., and, in any case, the cost of carriage must, in general, be added to the prices calculated from published unit values. Quantities of less than one ton are always charged at higher rates; in fact, gardeners who buy by the hundredweight are frequently charged double the price asked of farmers who purchase by the ton.—J. A. M.

MANURES AS SOIL IMPROVERS.— See *Soil Improvement*.

MANURES AND SOILS: Weight of Bushels of. — See Fertilisers, Manures, and Soils in *Weights and Measures*.

MANURING: Principles of.

The raw material which a plant builds up into food is drawn from two sources, namely, the air and the soil, and it is in connection with the latter source of supply that the question of manuring arises. Experiment has shown that the food which a plant requires can only satisfactorily be obtained if a certain number of substances are available in the soil-water. It is not essential to consider in detail each of these necessary substances, for in an ordinary soil it is probable that most of them will be present in sufficient quantity to grow an average crop. At a later stage in this article, detailed consideration will be given to those substances which are most generally found to be present in such small quantities as to limit the proper growth and development of the plant.

When the productive power of a soil diminishes, as it is often seen to do when heavily cropped, the cultivator must take steps to provide those substances which, through their absence or shortage, are preventing the plant from developing in a normal fashion. Even poor soils contain relatively large stores of material from which the plant may build up food, but these stores may be in an unavailable form. By cultivation and proper treatment this unavailable material may be converted into available substances which the plant can utilise. It is well that there should be this difference, for if all the crude plant-food were available at any one time, there would be danger of the surplus which the plant could not use being washed out of the soil and so lost.

The changes by which food material is gradually made available are complicated, and depend upon a number of factors, amongst which water (rain), air, heat, and the activity of micro-organisms are the chief.

When the substances which the plant requires are available they will dissolve in soil-water, and the weak solution so obtained is taken up by the root-hairs. This dissolved material is distributed throughout the plant, and as at the same time the leaves are probably engaged in manufacturing sugar and starch, the production of food for man and beast proceeds.

It was thought at one period that by analysing the soil, and ascertaining the quantity of food material in it, there would be little difficulty in providing the plant with what it needed. If the soil failed to contain the requisite quantities of the various foods, the cultivator only required to add that which was lacking in order to obtain a crop of maximum size. The results obtained, however, by working on these lines were in many cases disappointing, and this led to a close scrutiny of the whole question of crop growth.

An explanation of the failure was in some cases afforded by the difference (already mentioned) between available plant-food, and that which, although present in the soil, was not

in an available form. There still remain, however, a considerable number of difficulties to be overcome before the principles of manuring and plant-growth can be stated with certainty.

The subsoil cannot be left out of consideration, for the decay which is going on there continually provides the soil with material which can be utilised by the plant.

Although it is true that only slight reliance can be placed upon the information afforded by the analysis of individual samples of soil, there is, nevertheless, great assistance to be gained from the analysis of a considerable number of soils and subsoils. These analyses must, of course, be considered in conjunction with the details of crops grown upon the soils, and such other information as can be procured.

To the gardener dealing with a relatively small area of land, which has perhaps been heavily manured and cropped, the analysis of the soil can only be used to indicate broadly the treatment and cropping which are likely to give greatest returns. The main thing to recognise is that the available plant-food is rapidly exhausted in the average soil, and consequently that appropriate steps must be taken to make good these losses.

It is along two lines that the soil may be improved: (*a*) by accelerating the change of an unavailable plant-food into an available form, and (*b*) by the direct addition of some suitable manure.

In this connection there is one point which should be brought forward prominently, and that is the necessity of organic matter. The difference which is seen in the texture and colour of a well-cultivated garden as compared with the same soil growing farm crops, is largely to be explained by the greater amount of rotted organic material — or humus as it is generally termed— which the former contains. This humus plays a very important part in the growth of crops; not that it is itself a plant-food, but because it provides by its further decay the nitrogen compounds which the plant requires. Also, and this is most important, the humus improves the texture of the soil, making it more suitable for plant-growth, and producing a good tilth which is so essential in the preparation of a suitable seed-bed.

Humus as a soil improver acts in two main directions: first, it gives to the soil a much increased power to retain water, and further, by its decay it acts upon the store of plant-food which is not in an available form and renders the latter soluble and available; secondly, humus darkens the colour of the soil, and this condition is of advantage to the plant, seeing that the darker soils warm up more rapidly than do those of a lighter colour.

Soils, particularly those of the sandy character, fall in productive power largely on account of the decrease of humus. Such soils are often spoken of as hungry soils, and the best way to improve them lies in supplying them with an adequate quantity of organic matter, which by its decay shall replace the humus which has been lost.

Enough now has been said to indicate the main lines upon which the manuring of plants is based, and it now remains to consider more in detail the various groups of manures and their main characteristics. It is not proposed to deal with each individual manure, but to show the broad differences which exist between the various groups.

The Two Classes.—Manures are conveniently divided into organic and inorganic, and these divisions

correspond more or less closely with what are termed natural and artificial manures.

From what has been said in the foregoing, it will be understood that organic manures contain organic matter (either from plant or animal remains), and they yield the important material known as humus. In addition to the humus there is also nitrogenous material which undergoes a change (largely through the action of the soil bacteria), and ultimately yields the nitrates which are the chief source of supply of the nitrogen which the plant requires.

Such organic manures as dung, dried blood, rape dust, feathers, wool waste, etc., are used largely for the nitrogen which they contain, and which provides the nitrates so essential to plant-growth. Other manures of an inorganic nature, such as nitrate of soda, and sulphate of ammonia, also yield nitrates and in large quantities.

The ultimate effect of nitrogen is to promote the growth of leaf in the plant. Where a plant is not supplied with a sufficient amount of nitrogen, its leaf and stem plainly show by their poor development and pale colour that something is lacking. In such cases the use of a manure which contains nitrogen will excercise a very noticeable effect, and luxuriant deep green leaf growth will soon evidence itself. This rapid growth is particularly shown when a manure which is soluble and rich in nitrogen is applied.

Caution must always be exercised in the application of manures rich in nitrogen, for it is possible to overfeed the plant, and to get a rank leaf growth and not a well-balanced development. Also in this connection it must be borne in mind that excess of nitrogenous manure, once it has been converted into nitrates, is easily washed from the soil and lost.

Slow acting organic manures which have to undergo decomposition in the soil, and yield up their nitrogen gradually, are less liable to undergo this loss by washing out.

It may be mentioned also in this connection that plants which have been overfed with nitrogenous manures are more liable to be attacked by fungus diseases. The use, therefore, of quick acting nitrogenous manures, such as nitrate of soda or sulphate of ammonia, must be carefully carried out, and it is preferable to give such manures in two or even three doses rather than all at once.

Slow acting manures, such as dung, or other organic material containing nitrogen, can usually be given only at one time, and as the changes which have to be undergone by the material before it is soluble and ready for the plant take some time, there is little risk of any serious loss by washing out, provided always there are plants ready to take up the finished product.

It frequently happens that the growth of a crop is limited by the amount of phosphates which are present in the soil, and in consequence of this effect the use of phosphatic manures has become general. The effect of phosphates (or phosphoric acid as it is sometimes termed) is to keep the plant balanced, and to make it develop and ripen normally. This unbalanced growth is particularly noticeable in soils which are richly supplied with nitrogen, either naturally or by manuring. In such soils the plants tend to grow rankly, and not to produce seed or fruit in proper course. This effect of phosphates is also seen in wet seasons, when crops which are supplied with phosphate are usually found to ripen more satisfactorily and at an earlier date than those crops which are insufficiently supplied. Further, the

presence of phosphates assists the plant in the formation of root, and, as will be easily understood, good root development is essential if plants are to make maximum growth. Good roots also enable the plant to withstand drought.

Amongst organic phosphate manures there are various forms of bones, for example, bonemeal, steamed bone-flour, dissolved bones, etc. Guano and fish-manure also supply convenient quantities of phosphoric acid, whilst superphosphate and basic slag are the chief representatives amongst the inorganic manures.

In superphosphate and dissolved bones some of the phosphate is present in a water soluble form, and although this soluble phosphate changes into the insoluble state when it meets with lime in the soil, nevertheless, this latter form of phosphate is more readily available to the plant than the original phosphate. There is the advantage also that water soluble phosphate is distributed more widely in the soil than if it were in the solid form.

Basic slag is very finely ground in order that the insoluble-in-water phosphate which it contains may be distributed as much as possible, and be acted upon by the soil moisture and rendered soluble, and available for the plant.

It remains now only to mention the third material, viz. potash, which by its shortage may limit plant-growth. In soils of a sandy nature the quantity of potash is usually limited, and on such soils potash manures are practically certain to yield good results. The effect of the potash is perhaps not quite clear, but undoubtedly it influences the production of carbohydrate, *i.e.* sugars and starches. In consequence of this action plants provided with adequate supplies of potash yield bigger crops than those which are insufficiently supplied. The grain in a cereal crop, the weight of roots or potatoes lifted, and the quantity and quality of fruit, are all superior when potash is available.

Potash is supplied in farmyard manure, in wood ashes, and in the special potash manures such as sulphate or muriate of potash, and Kainit. Latterly it has been found that the dust from blast furnace flues contains considerable quantities of potash in some cases.

Details of how to apply these various manures will be found in the article on *Manures*, and also in the articles on *Soda and Sodium Compounds*, *Potash and Potassium Compounds*, which we hope will be carefully studied.

If a gardener or allotment-holder takes the trouble to understand the principles which underlie manuring, and if he then makes himself acquainted with the characteristics and properties of the several manures, he will be in a position to grow his crops more successfully, and with less cost, than if he relied upon some special manure which has been advertised as the very best for a particular crop or crops.

In conclusion, the article on *Lime* should be very carefully studied. Space does not allow of any mention of this material, but its importance cannot be over-estimated.

W. Gdn.

MANZANITA (*Arctostaphylos tomentosa*).—See *Shrubs*.

MAPLE.—A name applied to the genus Acer. See *Trees*.

MAPLE LEAF BLOTCH.—See under Sycamore Leaf Blotch in *Diseases of Plants*.

MAPLE-LEAVED GOOSEFOOT (*Chenopodium hybridum*). — See *Chenopodium*.

MARCH MOTH.—See under Winter Moths in *Insect Pests*.

MARE'S TAIL (*Hippuris vulgaris.* Nat. Ord. Halorageaceæ).—This is a useful perennial plant for the rougher portions of the water garden, growing about 1 ft. high. Once planted in a soft, wet spot it will look after itself.

MARGARET CARNATIONS.

These are hybrids between the Garden Pink and some of the Carnations. If sown early in heat and planted out they often bloom the same year. Planted in a frame they give flowers during the first winter after sowing, and are very useful for cutting, as well as free flowering.—S. A.

MARGUERITE FLY. — See *INSECT PESTS.*

MARIGOLD (*Calendula* and *Tagetes.* Nat. Ord. Compositæ).—Although many species of Calendula and Tagetes are recorded, very few of them are important as garden plants. Among the former that are hardy annuals, only two are in cultivation, namely, *Calendula arvensis*, the FIELD MARIGOLD, and *C. officinalis*, the ever popular common or POT MARIGOLD, which last has been in cultivation about 340 years.

Calendula arvensis produces yellow flower-heads throughout the summer, and is about 2 ft. high.

C. officinalis blooms from early June to late autumn in warm seasons, and grows about 18 ins. high, but may reach a height of 3 ft., when it has ample room and rich soil. The flower-heads of modern varieties are 3–4 ins. across and range in colour from pale lemon to deep orange. Some of the best varieties are: *Favourite* (pale sulphur, with creamy-white stripes); *Lemon Queen* (pale lemon-yellow, very double and a great favourite); *Meteor* (handsome yellow flowers, striped with lemon-yellow); *Orange King* (a splendid variety both in form, size and colour—deep orange, very double); *Prince of Orange* (rich orange with lemon-yellow stripes); and *Sulphur Queen* (light sulphur-yellow).

All the foregoing are double varieties with blooms 2–4 ins. across, but in light hot soils the flowers do not come so double as when produced from plants amply provided with food and moisture. Where these handsome old-fashioned flowers are loved, there should be two sowings: one in spring (March or April), and one in autumn (about mid-August). In the shrubbery border or odd corners, where they are especially serviceable, self-sown seedlings appear abundantly, and these need only be thinned to a foot or so apart, with an occasional hoeing among them while young, to produce a fine effect, but the flowers do not maintain the colouring and character seen in named varieties carefully selected raised year by year.

African Marigold.—The strong-growing, yellow-flowered African Marigold is a totally different plant to those referred to above. It belongs to the same Natural Order, but is a member of the genus Tagetes (*T. erecta*), and a native of Mexico. In its modern and improved varieties it is an excellent subject for garden decoration in summer and autumn, but it is tender, therefore seedlings should be raised in early spring in gentle heat and planted out at the end of May or early June, 1½–2 ft. apart, in a sunny position. Well-grown plants will grow 1½–2½ ft. high, and carry flower-heads several inches across, appearing most effective. The colour ranges from pale yellow to orange, and two of the best varieties are *Giant Orange*, double; and *Orange Beauty*, single. Most seedsmen offer good strains under colour only.

French Marigold. — The dwarf and very free flowering French Marigolds have been raised from *Tagetes patula*, a plant introduced to British gardens from Mexico a very long while ago. They should be treated like African Marigolds, except that they should be planted 9–12 ins. apart, and used for grouping or for marginal edgings to beds and borders. The tall, single-flowered French forms are scarcely so generally useful as the handsome dwarf varieties *Cloth of Gold* (rich yellow); *Diadem* (chestnut and red and yellow); *Legion of Honour* (yellow and brown, very popular); *Queen of Dwarfs* (double, brown and yellow); *Silver King* (pale yellow and maroon); and *Star of India* (crimson, striped yellow), which average 6–9 ins. high. Yellow, lemon, and blotched double forms are also offered by seedsmen under their colour.

Tagetes lucida and *T. signata*, with yellow flowers, have some merit, especially the *pumila* form of the latter species.—C. H. C.

See also *MEDICINAL HERBS*.

MARIPOSA LILIES, or STAR TULIPS (*Calochortus*. Nat. Ord. Liliaceæ).—This is an extremely lovely tribe of plants which for the most part come from California and other parts of North America. As they are very difficult to manage with any degree of success, no one is advised to attempt to grow them unless they have considerable horticultural experience and can give a good deal of attention to them. The great difficulties which have to be overcome are the cold rain and damp of winter and the proper ripening of the bulbs. Frame culture is almost essential, but in favoured positions they may be grown at the foot of a south wall in light soil.

The varieties of *C. venustus* are the most popular ones in the genus, and a colour range of yellow, lilac, rosy-purple, pure purple, pure red as well as pure white is available. They flower mostly in August, and average 1½ ft. in height.

J. J. & E. T. E.

MARJORAM (*Origanum Marjorana*). See *ORIGANUM* and *POTHERBS*.

MARKET GARDENING.

In this article the term "market gardening" is used in the older sense of the man who cultivates large quantities of fruits and vegetables for sale in the open market, and who has little glass at his disposal beyond a few lights or frames. The market "grower" is quite a different individual, although he also grows for market. His business is of such a nature as to necessitate large areas of glass structures to enable him to bring to perfection cucumbers, grapes, tomatoes, also foliage, and flowering plants in which he specialises.

Site for a Market Garden.—The man who wishes to succeed as a market gardener must be careful to select a site suitable for the purpose. He should avoid bleak, cold, and very hilly spots on the one hand, and very low, marshy, or swampy places on the other. He should seek to establish his holding at an elevation from 50 to not more than 300 ft. above sea-level, wherever the soil is of a good depth and of a loamy or silty nature. Heavy cold clayey soils should be avoided, as the cost of preparation will not only be great, but the crops on such a soil will always be much later than in more congenial localities. Before actually committing one's self to a certain site, it is always advisable to sample the soil in different places by digging a hole about 2–3 ft. deep, to see what

the upper crust is like, and also the subsoil. If rock of any kind is too near the surface, a site of this kind is best left alone. If fine sand or gravel comes some 2–3 ft. beneath a good loamy top soil, such a position may be considered suitable for market gardening. A chemical analysis may be helpful in deciding, but it does not follow that a correct deduction from a market gardening point of view may result. A man who is a practical fruit or vegetable grower is far more likely to give an accurate judgment on the value of a soil than the chemist, as many theoretical fruit growers have found out.

Situation.—In addition to a good site the question of locality is of some importance. The finest site in the world would be useless if it was too far from the market, from a railway, or if there were no workmen living within a reasonable distance. There are still many splendid market garden sites in the kingdom, but until other facilities develop, they must remain in embryo. It is obviously a wise proceeding to begin market gardening within a few miles of a large town or city, as it will not only be easier to market the produce, but also to secure supplies of manure and the necessary labour.

The Size of a Market Garden.—This depends upon the size of the market gardener's pocket. Still, there must be a minimum below which it would be unsafe to go, and this minimum should be about four or five acres. Of course, there are many men who make a living from a piece of land half this size, but as a rule they become more florists than market gardeners in a very short time, and they have to work hard and long to get the utmost out of their little holding. On the whole, a market garden of about 10 acres is quite small enough for a start. With luck and good management, combined with cultural skill, the area may be extended according to circumstances.

Obtaining the Site.—There are three ways in which a market gardener may commence business. First, he may prefer to rent a garden that is already established as a going concern. He will then probably pay an agreed price for the stock, and also an extra sum as "ingoing," and take over the usual liabilities of paying the rent, rates, and taxes, and keeping the holding in proper repair for the landlord. He should see that he does not sign any agreement with his eyes shut, as he will sooner or later find out that there are many little points in such that he will consider to be unfair to him, or they will at least cause him constant irritation.

Secondly, a man may rent a piece of land on the understanding that he is to make a market garden of it. Here again he must be careful to see that he gets what he wants, as ultimately all he possesses may go to the landlord. In this case a long lease, or one that may be renewed at a fair rental after a certain number of years, would be the most sensible way to go to work, taking care that he secures all the benefits of the Market Gardeners' Compensation Act.

Thirdly, perhaps the best method of securing a market garden would be to purchase the freehold of the land on reasonable terms. This may apply either to an established garden or to land intended for the purpose. An established garden would be suitable enough for a middle-aged man, who would not care to commence business from the very beginning, and who would prefer to get an immediate return

for his capital. He would, of course, have the disadvantage of having to take over the stock as it was, with all its faults of planting and perhaps overcrowding—faults in many old market gardens that could only be remedied at very great expense. A young and energetic man would be well advised to make a clean start, to plant his garden on the latest and most scientific principles, and to stock it with only the very best and most remunerative varieties of vegetables and fruit. Of course, it sometimes happens that a good bargain may be obtained in the way of a garden that has only been established a few years on these lines. Much time and money may thus be saved in such a case.

In connection with the purchase of freehold land it need hardly be mentioned that it would be well to obtain the services of a competent solicitor, as there are so many legal pitfalls into which the layman may easily drop before he is aware of it. A strict eye should be kept on tithes and other encumbrances that only come to light after everything has been "settled."

Capital Required.—It is impossible to give anything like a reliable estimate as to this, as conditions and prices vary so much in different parts of the kingdom. And so much depends upon whether a garden is rented yearly or on lease, or is purchased as a freehold. Assuming, however, that a man purchases a freehold of ten acres that is already fenced in or hedged round, and has a house, stabling, sheds, etc., attached, he should be able to place his hand on at least £200 or £300 to enable him to pay his way until his crops begin to turn into money. If he arranges to take possession at Lady Day instead of at Michaelmas, he will save about six months' expenses in labour, etc., and will commence taking money from the established fruit crops (such as gooseberries, for example) by the first or second week in June. These are points that a man brought up in the trade will know as well as anyone, but they are likely to be overlooked by one who takes a fancy to market gardening after he has tried perhaps at some other business.

Crops to Grow.—Assuming that one has the opportunity of starting a new market garden, and that all conditions are favourable, the first problem that arises is: how is the land to be planted or cropped to the best advantage? Taking 10 acres as a standard, it would be well to allot 7 acres to fruit culture, 3 acres to vegetables, and perhaps have a few flowers. The man who thoroughly understands fruit will probably plant nothing but fruit, and the same may be said of the man who specialises in vegetables and salads. A mixed garden, however, has the advantage of giving more than one string to the bow, and all the eggs are not in one basket. It sometimes happens that vegetables fetch very low prices, while fruit reaches a high figure, and one is therefore a set off against the other, even if the case is *vice versa*.

Out of the 7 acres of land devoted to fruit at least 4 should be devoted to apples, the other 3 being devoted to 2 acres of plums and 1 of pears. Taking everything into account, perhaps half-standard trees are more profitable than either standard or bush trees. The last named have certain advantages as regards the picking of the fruit, but they have the disadvantage of making it difficult to cultivate beneath them, also they prevent cropping underneath with

currants, raspberries, or gooseberries, as may be done with standard and half-standard trees.

It is usual in most market gardens to plant apples and plums in alternate rows, the idea being that the plums are to be cut out after fifteen or twenty years so as to give more room for the apples. This seems a sensible enough plan at the beginning, as both apples and plums in the infant stages appear to have plenty of space. Anyone, however, who has seen a market garden planted in this way at the end of the time mentioned will realise that it is not a wise proceeding. The apples are planted at 18 or 20 ft. apart, but the space for each tree is reduced to 10 ft., with the quicker-growing plums between them. At the end of ten, fifteen, or twenty years the plums have grown well into the apples, and unless they are cut out, as originally intended, both plums and apples are bound to suffer. The apple trees are just in their prime and so are the plum trees, and it requires a peculiarly hard-hearted gardener to destroy at one swoop trees that are likely to yield perhaps two or three bushels of fruit each. If, however, the plums are not cut out or restricted, a few more years of growth will simply smother the plantation, and result in distorted trees that will be blown to pieces by the strong winds. This is what may be seen in almost any market garden over forty years of age.

It is a much wiser plan to plant only 160 half-standard trees to the acre—that is, one to every square pole or rod—even if apples and plums are to be in alternate rows. They will then have just about enough space to enable them to grow into shapely trees, and with judicious pruning they ought to last anything from fifty to a hundred years, at least in the case of apples. The intervening space between the rows may be cropped with vegetables during the earlier years, so that the best use is made of the ground until the trees become too large and cast too much shadow to make vegetable-growing profitable. Personally, we think it much better to have the apples, pears, and plums in distinct quarters by themselves.

It is then possible to plant a row of free-setting varieties between those that are reputed to be shy setters. It is obvious that a shy-setting variety of apple, for example, stands a much better chance of being pollinated from a free-setting variety standing next to it, rather than from a plum or pear tree standing in the same place. Having apples, pears, plums, etc., in quarters by themselves not only makes it easier and more economical for picking, but it also assists the bees in their search for honey. When these industrious insects are visiting apples they are not likely to visit the blossoms of cherries, pears, or plums at the same period. Consequently the chances of having the pollen carried from one tree to the next are facilitated by planting the same kinds (not varieties) of fruit together.

Intercropping with Bush Fruits.—Where half-standard or standard trees are used instead of bush trees, it will be possible and advisable to utilise the intervening space for currants, gooseberries, and raspberries. About 1500 currant or gooseberry bushes may be planted to each acre, or about 2000 raspberry stools. They may be planted between the rows of trees and also in a line with them, thus utilising space to the utmost. In the early years there will still

be room for raising vegetables, but this must cease as soon as the bushes have filled out to occupy the space.

Other Fruits.—In certain parts of the country, such as Kent, cherries and cobnuts are popular crops. In most places, however, these are not attempted, but they should be grown when the local conditions are favourable. Strawberries, although a fruit in the technical sense, are also best grown in localities where they revel, such as in the neighbourhood of Southampton and Wisbech.

Varieties to Grow.—It is somewhat difficult to give a list of fruits that are likely to succeed in every part of the kingdom. One should look round the market gardens in any locality in which it is intended to plant, and find out which varieties "do" best in that particular neighbourhood. The following, however, may be taken as a good list of marketable fruits that are grown in large numbers in some parts of the country.

Dessert Apples.—Mr Gladstone, Lady Sudeley, Worcester Pearmain, and Devonshire Quarrenden for marketing in early and late August. These are all first-rate market varieties, but it may be remarked that while Worcester Pearmain is a great favourite with Middlesex and other growers, it is considered to be useless in the Wisbech area.

Cox's Orange Pippin, considered to be still the prince of dessert apples, does not thrive in every locality, and one should make quite sure of its cropping qualities before planting it largely. Where it does thrive it may be regarded as one of the surest moneymakers amongst apples. Allington Pippin and Charles Ross are both seedlings from this variety, and they are gradually being taken up by growers. Some say, however, they are too large for dessert purposes. This may be so in the case of young trees with only a few fruits upon them, but with heavier crops on older trees this objection is likely to be removed.

Beauty of Bath is an early variety, but it seems to be unreliable. James Grieve, however, is an apple that is likely to become generally grown. It has a touch of Cox's about it, and it seems to be a good cropper in most localities. The old King of the Pippins still wants a lot of beating where it does well, and the same may be said of Ribston Pippin. A reputation for canker has prevented the last-named variety from being planted much of late years. If, however, the soil is deeply tilled and of a genial nature, it does well. The reader may extend this list at will according to local knowledge.

Cooking Apples.—The varieties here mentioned are looked upon as good reliable croppers, but there are many others that flourish as well, if not better, in various localities. Generally speaking, it will pay the market gardener to grow a few varieties of either dessert or cooking apples in large quantities, rather than have a small quantity of many varieties for market. The following varieties may be grown with safety in most places:—Emmeth Early (or Victoria), Keswick Codlin (an old variety, but nearly always reliable as a cropper), Bramley's Seedling (a great favourite in the Wisbech district), Warner's King, Newton Wonder, Stirling Castle (an excellent polleniser for other varieties, and also a heavy cropper), Lane's Prince Albert, Lord Grosvenor, Lord Suffield, Grenadier, Lord Derby, Bismarck, Golden

Spire, Wellington or Dumelow's Seedling, and others.

Pears.—There are a host of varieties, but the market gardener will do well to confine himself to comparatively few, unless he has a very large acreage at his disposal. In old gardens the Duck Egg still holds a reputation which choicer varieties do not bear. It would not, however, be planted by any modern grower, as there are now many finer varieties that are more worthy of space. The Lammas is another very old Pear in the Home Counties. The Hessle (or Hazel, as it is always called) is a good market pear and grows better and finer in Middlesex probably than anywhere else. It is nearly always a good cropper, but misses a year now and again as in 1918. The Calebasse is also a good variety, and the same may be said of the Windsor, Glou Morceau, Marie Louise, and the old Jargonelle. Fertility is a very heavy cropper and is well worth planting. Among the choicer pears for market, Durondeau, Clapp's Favourite, Dr Jules Guyot, Conference, Souvenir du Congrès, Beurré Hardy, Beurré Superfin, Easter Beurré, Beurré Clairgeau are all proved varieties; while what is considered the finest pear of all—Doyenné du Comice—should find a good place either as a pyramid, standard, or as espaliers or cordons. Where any of these varieties (or any other, for that matter) do well, the grower can hardly make a mistake in planting them. For stewing purposes Catillac may be recommended, as it keeps till Christmas. It is unnecessary to give descriptions of these varieties, as they are detailed in almost every fruit catalogue.

Plums.—Rivers' Early Prolific, The Czar, Victoria, Prince of Wales, Belle de Louvain, Belle de Septembre, and Monarch are among the best market sorts. Gisborne is a heavy cropper and early, but it seems to be vanishing through the ravages of the terrible Silver-leaf disease—for which it may be emphatically said there is not at present either preventive or cure. The Pershore Plum is grown largely in places, and Heron is gradually making a name for itself. Orleans is a good plum and generally bears well, although it misses a season now and again. Pond's Seedling is a big red plum favoured by some; and in old gardens, Dovebank or Goliath often bears heavy crops, but is becoming obsolete.

Vegetables.—A market gardener will naturally grow the kinds he has most sale for, and he will also have them in great abundance so as to make it worth while preparing them for market. Amongst the most profitable crops are cabbages for spring, summer, and autumn use; cauliflowers and broccoli; Brussels sprouts and borecole or kale for winter and early spring use; lettuces (cos and cabbage), for all seasons if necessary; radishes as early in the year as possible and as long as possible, as they are nearly always sure to pay. Rhubarb is almost essential, and may be grown between trees if nothing else is on the ground, early supplies being obtained by covering the stools with litter as early in the year as possible. Onions are a good crop in all stages of growth if kept clean, and so are beetroot, carrots, leeks, parsnips, and turnips. Where the soil is of a nice silty nature and well exposed to the sun, asparagus is a profitable crop. Indeed, almost any kind of well-known vegetable will sell if properly grown, and the better it is grown and packed, the more likely is a ready sale at good prices. Broad Beans are

nearly always grown when space permits, and also Runners and French Beans.

Flowers.—The modern market gardener does not despise growing flowers and bulbs wherever he can find room for them. Campanulas, chrysanthemums, daffodils, dahlias, foxgloves, irises, narcissi, paeonies, pansies, sweet peas, violas, and many others find a place in several gardens, where the revenue from them is often considerable, and helps to keep the gardener's spirits up when prices for other produce are perhaps below the normal.

From what has been sketched in this article it will be gathered that the market gardener is likely to be a very busy man, and must not only work hard with his hands, but also with his brains, if he is to make a success of his business.—J. W.

MARRAM GRASS.—See *AMMOPHILA.*

MARROWS.—See *VEGETABLE MARROWS.* For METHOD OF BOTTLING see *VEGETABLE BOTTLING.*

MARRUBIUM (WHITE HOREHOUND. Nat. Ord. Labiatæ).—This is a small genus of hardy herbaceous perennials of very easy culture but of no great garden value. It may be propagated by seeds, cuttings, or root division at the usual times. It must be distinguished from the form of Horehound referred to in our article on *BALLOTA*, which see. As a medicinal plant White Horehound is now discredited.

The best known species is *M. vulgare*, a weedy plant known to collectors as the COMMON WHITE HOREHOUND. *M. Pseudo-dictamnus* is now considered synonymous with *Ballota Pseudo-dictamnus* (see *BALLOTA*). Choicer species are *M. astracanicum* (blue) and *M. catariaefolium* (purple). Both bloom in July, and average 12–18 ins. in height.

MARSH ARROW-GRASS.—See *ARROW-GRASS.*

MARSH BUCKLER FERN (*Nephrodium Thelypteris*).—See *FERNS AND FERN GARDENING.*

MARSH HEATHER (*Erica Tetralix*). See *HEATHS.*

MARTAGON LILY (*Lilium Martagon*). See *LILIES.*

MARTYNIA.—See *ANNUALS, HALF-HARDY: LIST OF,* and *UNICORN PLANT.*

MARUTA.—Now included in the genus *ANTHEMIS.*

MARVEL OF PERU (*Mirabilis.* Nat. Ord. Nyctaginaceæ).—This is a genus of greenhouse or half-hardy herbaceous perennials easily raised by seed sown in a warm house or hotbed. When sufficiently strong the plants should be hardened off to stand in the open border. The roots should be lifted in the autumn and preserved in dry sand

or moss during the winter. The plants are, in fact, treated exactly like *Dahlias*, which see. The seed is generally sold in mixtures and germinates freely in rich sandy loam. Temperature needed 40–50° F.

What to Grow.—We recommend the following :—

Mirabilis dichotoma. — Yellow. Flowers in July and August. Height, 2 ft.

M. longiflora. — White. Flowers in July and August. Height, 2 ft.

M. longiflora carnea. — Pink. Flowers in July and August. Height, 2 ft.

MARY'S THISTLE. — See Holy Thistle in *Medicinal Herbs.*

MASDEVALLIA.—See *Orchids.*

MASIRO GUMI (*Elaeagnus umbellata*). See *Shrubs.*

MASK FLOWER.—See *Alonsoa.*

MASTER-WORT (*Peucedanum Ostruthium*).—See *Peucedanum.*

MAT-WEED.—See *Nardus.*

MATRICARIA (Nat. Ord. Compositæ). — The common May Weed of the cornfields is closely allied to the Chamomile and Feverfew, and is something of a pest, but under cultivation it has been turned into a beautiful decorative plant, which, while not an annual, may be treated as such, and raised from autumn or spring sowings. Planted out about 6 ins. apart in early May plants of the double-flowered varieties will subsequently produce a mass of snow-white blooms raised a foot or more above the ground. In modern botany the genus Matricaria is merged into Chrysanthemum.

Matricaria inodora flore pleno, the botanical name of the above, is a white summer and autumn flowering plant. Its variety *Bridal Robe* is about 1½ ft. high, and is fine alike for grouping or cutting. *Snowball* is suitable for borders or beds, or for cutting, and grows 2–2½ ft. high.

Perennial Border Species.—These when compared with the above are comparatively poor, though of very easy culture. The best is *M. Tchihatchewii*, a white species blooming in July, and growing about 12 ins. high. It spreads too rapidly for choice places.

See also under Chamomile and Feverfew in *Medicinal Herbs.*

MATS.

Archangel and Dunnage mats are quite the best for use in the garden, and last if properly looked after for a long period. In practice, however, old carpets, door-mats, old rugs, and other similar materials are pressed into service for protecting frames, etc. Mats after use should be well shaken and either laid out or hung up in some warm place to dry thoroughly before being put on the frames the following evening.

MAY WEED.—See *Matricaria.*

MAZUS (Nat. Ord. Scrophulariaceæ).—A genus of dwarf trailing and creeping plants which thrive in sunny positions in well-drained soil in the rock garden or border. They are propagated by division in the autumn or spring. There are two species suitable for the rock garden.

Mazus Pumilio.—A creeping plant. Flowers pale violet, large. Site sunny. Soil sandy loam in joints of

flagstones or rocky places. Flowering Period, May to July. Height, 2 ins.

M. reptans.—A prostrate species. Flowers pale violet, spotted. Site sunny. Soil moist, well-drained. Flowering Period, June to July. Height, 2 ins.

MAZZARD (*Prunus Avium*). — See *TREES.*

MEADOW CLOVER (*Trifolium medium*).—See *TRIFOLIUM.*

MEADOW FESCUE (*Festuca elatior pratensis*).—See *FESTUCA.*

MECONOPSIS (HIMALAYAN POPPY. Nat. Ord. Papaveraceæ). — This family includes some useful plants for garden decoration, most of which are of easy culture, thriving in any ordinary light garden loam containing plenty of grit, in a sunny or lightly shaded spot. The annual and biennial species are best propagated by seeds sown in the usual way and at the usual times for such subjects; the perennial species may be increased by division of the roots in March or April, which months are the best times for planting, and also they may be raised from seeds sown in a frame at that time. With regard to the duration of each species, it is stated according to the authorities at Kew. The genus is one upon which much further study may profitably be expended.

Annual Species.—These are perhaps the least important. We recommend the following:—

Meconopsis heterophylla (Syn. *M. crassifolia*).—This attractive species bears orange-red flowers from June to September, and grows about 1 ft. high.

Biennial Border Species. — Excluding the three biennial species described under the rock garden species below, which are not very suitable for border work, we recommend the following:—

Meconopsis nepalensis (NEPAUL POPPY).—This showy plant bears purplish flowers in August and September, averaging 2½–5 ft. in height.

M. paniculata.—This is an ornamental species bearing pretty yellow flowers from midsummer onwards, and growing 3–6 ft. in height.

M. Wallichii (SATIN POPPYWORT).—This is a favourite species bearing attractive blue flowers from June onwards into the autumn. Its average height is 3–6 ft., but when drawn up it may exceed 7 ft.

Perennial Border Species.—Only one species is strictly perennial. This, *Meconopsis cambrica,* the well-known WELSH POPPY, is very suitable for the herbaceous or mixed border if a shady spot can be

found for it. We describe it fully in the rock garden species below.

Rock Garden Species.—The following four species are suitable. These need a shady corner, and are propagated by seeds sown in heat in March. *Meconopsis cambrica* is a hardy perennial; the others are hardy biennials.

Meconopsis aculeata.—This is of erect habit, and its leaves are covered with white hairs. Flowers blue. Site, shade. Soil peat and loam. Flowering Period, May to June. Height, 2 ft.

M. cambrica (WELSH POPPY).—This is of tufted habit. Flowers yellow. Site, shade. Soil rocky. Flowering Period, May to September. Height, 1 ft.

M. racemosa.—This has its entire leaves in rosettes. Flowers blue. Site, shade. Soil peat and loam. Flowering Period, May to June. Height, 2 ft.

M. simplicifolia.—This is a somewhat trying sort to grow, and bears rosettes of entire leaves and single-flowered scapes. Flowers blue. Site, shade. Soil peat and loam. Flowering Period, June. Height, 1 ft.

Other species suitable for this purpose are *M. integrifolia*, with yellow flowers; *M. latifolia*, pale blue; and *M. Pratii*, dark blue.

NEW VARIETY.

Meconopsis simplicifolia, Bailey's Variety.—This has hairy leaves and sky-blue flowers, with deep blue filaments and yellow anthers. It grows about 16 ins. high.

MEDICAGO (MEDICK. Nat. Ord. Leguminosæ).—This is a large genus of hardy annuals and hardy herbaceous perennials of the easiest culture, though not much grown. The most interesting species is *M. Echinus*, the well-known CALVARY CLOVER, best raised as a half-hardy annual and planted out. Other species are more useful to the farmer, such as *M. maculata* (Syn. *M. arabica*), the HEART CLOVER, and *M. sativa*, the useful forage crop known as LUCERNE. Two other species we may mention are *M. lupulina*, the BLACK MEDICK, and *M. scutellata*, the SNAIL MEDICK. These are not of much garden value.

MEDICINAL HERBS.

Introduction.—Until August 1914 the British druggist was accustomed to import the greater proportion of the Vegetable Drugs that he required from foreign countries, including a very large number from Germany, and when the War stopped this importation, as was but natural, the prices of these drugs rose enormously, and in some cases it was impossible to obtain supplies at all.

Realising the necessity of growing the more important Medicinal Herbs in this country, the Board of Agriculture issued a leaflet, No. 288, urging their cultivation and collection. This was taken up by the public, and all and sundry started growing and collecting Herbs, sending to druggists many useless samples which had to be destroyed.

To encourage the growing of Herbs in British gardens, we are describing a very large number of those used in medicine, giving some brief cultural notes where necessary, and information as to the part required. We think that this article on Medicinal Herbs is one of the most important features of the work, as no such comprehensive notes on all the principal Medicinal Herbs have as yet found a deserved place of honour in other gardening works. There are one or two special books on Herb Gardening it is true, and many pamphlets, but since Herb Growing is, we are sure, going to be an important industry now the War is over, we give it more space than would otherwise seem necessary.

The writer of the Herb Notes is an expert in her subject, and we are indebted to her for the trouble she has taken in giving us the practical information we desire. Reference should also be made to the article on *HERB GARDENING* by another Herb Growing Expert, and a plea may well be made

for the systematic study of this all-important subject. Fortunately there is a School of Herb Growing now at Chalfont St. Peter, Bucks, where those who have time, and who wish to take up the industry seriously, may go and study the whole question under expert Herb growers. For women and discharged soldiers who are unable to follow the more strenuous sides of Gardening, such as Fruit Growing and other similar work where much hard labour is required, Medicinal Herb Growing as a profession should commend itself, as after the experience has been gained, all it needs is patient trouble and light hand work. Many of the Herbs grow better in England than in other countries, though this fact is not generally known, and there is an enormous scope for those who have sufficient patience in the improving of drug-yielding Herbs. A case in point may be mentioned in Aconite (*Aconitum Napellus*), of which there are so many garden varieties. Careful trials should be made, and the sorts determined which contain the largest percentage of the drug. Again, species with a poor drug-bearing capacity but of easier culture, might well be crossed with those of more difficult culture which contained a larger portion of the drug, in the hope of obtaining a plant of easy culture with a fair drug-bearing capacity. These are only a few of the many possibilities of the subject.

Regarding the matter of drying the Herbs, this is probably the most important part of the industry, but it is by no means a simple matter, and thus we are unable to give full details here. The main thing for the gardener to do is to grow the Herbs, and communicate with the School of Herb Growing, or the various Herb Growing Associations, who will buy the herbs in an undried condition, and dry them at their own expense in their own apparatus. Amateurs are almost certain to spoil the Herbs if they attempt to dry them in their own way.

It may be asked which are the dozen Herbs which are most in demand, and we may say that these are the following: Aconite Roots, Asparagus Roots, Belladonna (whole Herb), Burdock Roots, Buttercup Roots, Comfrey Roots, Dandelion Roots, Dock Roots, Iris Roots, Meadowsweet Roots, Parsley Roots, and Rhubarb Roots. Only a few days ago the present writer received a letter offering to buy any quantity of these dozen Herbs for Medicinal purposes, from a Herb drying house, and his only regret was that up to the present time his energies have been entirely concentrated on vegetable growing, and that thus Herb Growing and collecting have been out of the question.

It is, of course, of great importance that leaves, flowers, or Herb Roots should be carefully packed, as otherwise they may become spoiled or damp in transit, and then be of no use when they reach their destination. One School of Herb Growing offers to pay prompt cash for any consignments fit to use on arrival, and points out that as a rule a sample must first be sent, as it takes no responsibility for consignments arriving without any previous intimation. In conclusion, it may be well to point out that any question relating to technical points on Herb Growing should be addressed, not to nurserymen, as is usual, who have not made a special study of this subject, but to the Herb Growing Schools, and the local Herb Growing Associations. We now give notes on all the important Medicinal Herbs below, under the names by which they are known to Herbalists. The letters following them signify as follows: *B.P.*, British Pharmacopœia; *B.P.C.*, British Pharmaceutical Codex; *H.*, Homeopathy; *S.*, Simple, *i.e.* Herbalist Drug.

Aconite (*Aconitum Napellus*. Syns. MONKSHOOD, WOLFSBANE. Nat. Ord. Ranunculaceæ), *B.P. & H.* — This is used as an anodyne, febrifuge, and diuretic. It is one of the most important of the pharmacopœial plants, and requires careful cultural study for the improvement and standardising of the strain. It is the source of a powerful and poisonous alkaloid, Aconitine.

DESCRIPTION. — Monkshood is a fairly well known plant, and often cultivated in gardens; it is also found in the wild state. Its tall blossoming spike, unlike the larkspurs, is composed of dark purplish-blue flowers, the topmost petal of which is boldly helmet-shaped, or somewhat like a monk's hood. It is a perennial, growing in damp, shady places, and blossoming from June to September. Every part of the plant is highly poisonous.

CULTIVATION.—Seed will not as a rule germinate unless sown as soon as it is ripe in August, but propagation is simpler by division of the roots. The Homeopathic Pharmacopœia recognises three foreign species of Aconitum in addition to *Aconitum Napellus*, but the B.P. mentions only the latter. Catalogues of the larger horticultural firms enumerate ten or eleven differently named and coloured Aconites, all of which succeed under the shade of trees and may be grown in the ordinary way as border or shrubbery plants in moist and slightly retentive loamy soil. There are twenty-four or more wild varieties, but it is not known how far these vary in medicinal value, nor which are the strongest growers. Cultural experiment to determine these points would be of great service to British medicine, and to the British herbal industry.

MARKETING.—The root from mature plants is the part required. The cultivated root is greatly superior, from a medicinal point of view, to the wild root marketed by collectors. The herbaceous parts of the plant are not required, although seed might always be saved. The roots should be dug in autumn when the leaves have died away. They should not be washed but shaken free from mould and dried on open-meshed sieves or racks in a current of warm air until they are shrunk and firm and break with a brittle fracture. The grower should carefully study the appearance of a good sample of the commercial article—to be obtained probably through the courtesy of any chemist—and should read the official description of this in the B.P. under the heading "*Aconiti Radix*." He must remember that all parts of the plant are highly poisonous, and that the root has often been mistaken, with fatal results, for that of horseradish. Only intelligent persons should deal with the harvesting of this crop, and only then if their hands are free from wounds or abrasions or are protected by gloves. The current price of Aconite root per pound or per ton may be ascertained by consulting any of the commercial journals of the pharmaceutical trade. This remark holds good with regard to all the more important materia medica.

Agrimony (*Agrimonia Eupatoria*. Nat. Ord. Rosaceæ), *S.*—A well-known, almost ubiquitous perennial herb which is required by certain firms of druggists in such quantity that it has been mentioned among wild plants as one which would possibly repay for cultivation.

American Horsemint.—See article on *POTHERBS*.

Anemone.—See under PASQUE FLOWER farther on.

Angelica (*Angelica Archangelica*. Nat. Ord. Umbelliferæ), *S.*—This is used as a stimulant, carminative, diaphoretic, and expectorant, also used in the confectionery trade for flavouring purposes.

DESCRIPTION.—The plant occurs wild only as an escape from cultivation. It is tall, stout, and perennial, and has large leaves and umbels of greenish-white flowers. See *Flowers of the Field*, fig. 220.

CULTIVATION.—Sow seed in the open in March in a damp sandy soil, and thin out seedlings to about 18 ins. apart, as soon as large enough.

MARKETING.—The well-grown succulent stalks are chiefly required. There is also a market for the seed and roots. All need to be dried. Angelica should not be grown as a speculation, but only in response to ascertained requirement.

"Aniseed."—The B.P. preparations from Anise fruit (so-called "seed") are derived from two plants: one, *Pimpinella anisum*, belonging to the Natural Order Umbelliferæ; the other, *Illicium verum*, belonging to the Natural Order Magnoliaceæ. The former is cultivated in Egypt, Germany, Spain, and elsewhere; the latter in warm countries. The medicinal properties of these fruits are aromatic, carminative, and pectoral, but it is to be doubted if their cultivation could be undertaken with any degree of commercial success in this country.

Balm.—See article on *POTHERBS*.

Basil.—See article on *POTHERBS*.

Bearberry (*Arctostaphylos Uva-ursi*. Nat. Ord. Ericaceæ), *B.P. & H.*—This is used as an astringent, diuretic, and sedative to the bladder.

DESCRIPTION.—A small prostrate perennial shrub found in moorland country and on mountainous heaths. It has small evergreen leathery leaves, rose-coloured flowers (May to June), and scarlet berries.

CULTIVATION.—It can be grown from seed taken from wild specimens, but only in localities similar in character and altitude to its native habitat.

MARKETING.—Separate the leaves from the stalks and thoroughly dry.

Belladonna (*Atropa Belladonna*. Syn. DEADLY NIGHTSHADE. Nat. Ord. Solanaceæ), *B.P. & H.*—A powerfully poisonous perennial plant. See precautions as to growing and harvesting noted under ACONITE. It finds application as a narcotic, anodyne, mydriatic; and is the source of the important alkaloids Atropine, Belladonine, etc.

DESCRIPTION.—Belladonna is found in the wild state, but it cannot be said to be common. It is a stout, erect herbaceous plant which branches and often attains a height of 3–4 ft. Its leaves are large, stalked, ovate in shape with an acute apex, and grow in unequally sized pairs. The flowers are axillary and solitary, purple and bell-shaped. The fruit is like a small black cherry with a persistent calyx. It is found in quarries and about old ruins, in shady places on chalk and limestone soils.

This plant is one of the most important from a medicinal, and remunerative from a commercial point of view, to which the herb grower can devote his time and attention. It is one of the comparative few for which there is always a demand and a market; one of those, moreover, which would repay for expert cultural study. As more information has been forthcoming in the pharmaceutical and horticultural press on belladonna growing than on any other medicinal herb, it seems unnecessary to take up space here on the matter.[1]

MARKETING.—The roots, leaves, and seeds are required, the former chiefly, which should be four years old. From first year plants leaves may be gathered in September. In the second season the entire crop is sickled down when in flower in June, and a second crop is available usually in September from the same plants. The same remark applies to the third year. In the fourth year only part is harvested as above, the rest being left to seed, which is usually ripe in September. The root can then be dug in November. It must be noted that the leafage should be consigned to the buyer the same day or carefully dried at once, otherwise it will ferment in a few hours and be spoilt.

Betony (WOOD BETONY).—See article on *POTHERBS*.

Bistort (*Polygonum Bistorta*. Syns. SNAKEWEED and SNAKEROOT. Nat. Ord. Polygonaceæ), *S.*—A highly astringent herb in action, said to be valuable as a wine in the early stages of phthisis. The herb was at one time much cultivated for its medicinal qualities and is not unlikely to revive in favour, since these have again been recently recognised and scientifically confirmed.

DESCRIPTION.—A handsome perennial plant about 2 ft. high, found growing in circular patches in moist meadows. Leaves radical and cauline, ovate; flowers (produced from June to September) pink, in dense terminal spikes.

CULTIVATION.—Any portion of the twisted rhizome or underground stem will grow, so that it is only necessary to transplant a piece of this to the space allotted to bistort in the herb-garden to secure a crop. The plant, indeed, is very hard to eradicate once it has gained a hold. It flourishes in most ordinary soils, especially if they are moist and in a good state of cultivation.

MARKETING.—The rhizome is dug in September from plants not more than two to three years old. It should not be washed, but freed from earth, and dried like any other root crop.

Blue Bottle.—See CORNFLOWER.

Borage.—See article on *POTHERBS*.

Buck Bean (*Menyanthes trifoliata*. Nat. Ord. Gentianaceæ), *H.*—A beautiful but little known plant found in water or very wet situations. Its cultivation should be confined, for the present, to encouraging its increase in its natural haunts.

MARKETING.—The entire herb is wanted.

Burdock (*Arctium Lappa*. Nat. Ord. Compositæ), *B.P.C.*

DESCRIPTION.—A well-known biennial plant found all over the country, chiefly on roadsides and in neglected corners of fields. It sometimes grows to a very considerable height and forms familiar rough burr-like heads of seed which cling to everything they touch.

CULTIVATION.—Burdock is much pressed not only upon the collector's attention, but upon that of the herb grower. The dried root from plants

[1] Miss Teetgen's *Profitable Herb Growing and Collecting*, published by Country Life Ltd., deals with the culture of this herb very fully, and a useful leaflet on it entitled *Belladonna* has been published by Mrs. Grieve, of Chalfont St. Peter.—EDITOR.

of the first year's growth is the part chiefly required, although there is also a market for the leaves and seed. Burdock succeeds well in almost any soil provided it is rich in humus and well drained. The seed may be sown out of doors early in the spring in drills 18 ins. to 3 ft. apart, and not more than 1 in. deep. Seedlings should be thinned out to a foot apart to allow for the growth of the large leafage, and the plants should be carefully cultivated as long as their size will permit. At the end of the first year's growth the tops may be cut and the roots turned out with a deep-running plough, or beet lifter. Extra large or deep-growing roots will require hand digging to prevent breakage and injury.

MARKETING.—Burdock root is large, thick, and heavy. It should not be washed, but shaken or rubbed free of soil, and dried in artificial heat (to about 100° F.) until it breaks with a short fracture. Slow, natural drying merely shrivels the root and it will not snap at all, but is leathery and tough. It loses very considerably in weight and in size in drying, some five tons of the fresh material being required to yield one of the commercial product.

Calamint.—See article on *POTHERBS*, and separate article.

Calamus.—See SWEET SEDGE.

Caraway (*Carum Carri*. Nat. Ord. Umbelliferæ), *B.P.*—This is used for aromatic and carminative purposes.

DESCRIPTION. — A biennial herb growing to about 2 ft. in height, found wild only as an escape from cultivation, and bearing small greenish blossoms. Leaves bi-pinnate and much cut.

CULTIVATION. — This is similar to that for CORIANDER, DILL, and FENNEL (which see), and is entirely suitable to be carried out on a small scale of farming. The plant succeeds well in a loam or stiff clay soil.

MARKETING.—Reap at the end of the second season. The so-called "seed," or fruit, is thrashed out just before it is quite ripe. It must be "clean," dry, and graded according to size.

Cascara Sagrada (*Rhamnus purshianus*. Nat. Ord. Rhamnaceæ), *B.P.*—A powerful cathartic.

CULTIVATION AND MARKETING.—This is not a British plant, but an American. There is no climatic or cultural reason, however, why it should not be grown in this country as a hedge tree. The bark is required, and the B.P. directs that it should be collected (and dried) one year before use.

Catmint.—See article on *POTHERBS*, and separate article.

Chamomile (*Anthemis nobilis*. Nat. Ord. Compositæ), *B.P. & H.*—This is used as an aromatic stimulant and bitter tonic. The herbal infusion of Chamomile flowers, which should be clear and brilliant as a very pale sherry (without filtering), taken in wineglassful doses before meals three times a day, is an excellent appetite restorer. It can be flavoured with a dash of lime or lemon juice if desired.

DESCRIPTION. — Chamomile (often also called ROMAN or COMMON CHAMOMILE) is found in the wild state growing generally in sandy waste places all over the country. Its finely cut thread-like leaves and daisy-like heads need little description. But the medicinal plant is a carefully cultivated variety bearing double flowers, and could not, probably, be satisfactorily grown from seed collected from the wild. It is a perennial zealously kept true to required strain by division of the roots, and by subsequent careful culture. The tendency is to go back to the single-flowered variety. GERMAN CHAMOMILE (*Matricaria Chamomilla*) is also a common English annual herb very much like the wild Roman Chamomile. It is sometimes called WILD CHAMOMILE to distinguish it from the latter. Roman Chamomile has a flat or slightly depressed floral disk or "capitulum"; German Chamomile has a protuberant conical disk. The distinction is important. German Chamomile tends to produce the requisite double blossoms if carefully grown on stiff black loam, which soil also produces the heaviest crop of Roman Chamomile, so that the two are often cultivated and harvested together under similar conditions. If either are grown in soil too rich, the product is not satisfactory, the size of the centre of the flower being reduced. The single blossom should never be offered or substituted for the double, but merely encouraged to become double itself under suitable conditions.

CULTIVATION.—It is not safe to raise Chamomile from seed owing to this variability in the quality of the blooms produced, but by division of the roots of tested and satisfactory

stocks. Each plant throws off ten to twelve suckers or "offsets." Divided up accordingly, the new roots should be set out in March at intervals of 18 ins. apart, in rows 2 ft. asunder, and pressed firmly into the bed. They require careful weeding by hand rather than by hoe, also water until established, and spread rapidly. Old clumps should be divided and replanted every second year.

MARKETING.—The flowers are required; they should be picked on dry days only, after the morning dew is past, as they appear throughout the season from July to September, and be dried quickly in small instalments to preserve the whiteness as much as possible. Chamomile is sorted and graded and valued entirely by colour; brown and yellowed blossoms detracting greatly from the product. From 5 to 6 lb. of fresh flowers produce 1 lb. of dry. The market for Chamomile is steady and fairly remunerative.

Chervil.—See article on *POTHERBS*.

Chicory (*Cichorium Intybus*. Nat. Ord. Compositæ).—This is used as a flavouring agent.

CULTIVATION.—A well-known tall blue-flowered perennial, which thrives in chalky soil. Sow seed in well-dug ground in April.

MARKETING.—The root is the part required. Dig in the autumn of the second year. See also article on *SALAD PLANTS*.

Comfrey (*Symphytum officinale*. Nat. Ord. Boraginaceæ), *H.*—This is used as a demulcent and astringent.

DESCRIPTION.—A tall forage plant, with large rough leaves and a row of drooping white or mauve flowers borne on one side only of the stalk.

CULTIVATION.—The plant will grow well in moist situations, and is easily propagated by division of the roots in the spring.

MARKETING.—The herbaceous portion harvested and dried in May is chiefly required, also the root, which should be root dried in October.

Coriander (*Coriandrum sativum*. Nat. Ord. Umbelliferæ), *B.P. & H.*—This is used as a carminative and aromatic.

DESCRIPTION.—A slender annual with few-rayed compound umbels with white, sometimes slightly pinkish little blossoms, the outer ring of which have larger, more conspicuous petals than the central ones. It flowers in June, and the "fruit" is set shortly afterwards.

CULTIVATION.—Coriander is quite an easy herb to grow. Its culture, like that of CARAWAY, DILL, and FENNEL (which see), needs to be encouraged and increased in this country and should be undertaken on a farming scale, or by a group of small growers in one district on a co-operative basis. It should be sown in ploughed, well-prepared ground early in the spring in shallow drills 2–2½ ft. apart. The crop likes a warm light soil, but will also succeed on loam and clay. Seed germinates quickly.

MARKETING.—The herb is mown down before the "fruit" is quite ripe, and after an interval during which this matures and dries, the heads are thrashed. The "seed" is sold at about 5d. per lb. It is very rich with highly aromatic oil. There is a steady demand for it.

Cornflower[1] (*Centaurea Cyanus* and other varieties. Syn. BLUE BOTTLE. Nat. Ord. Compositæ).

DESCRIPTION.—A familiar garden plant, easily grown.

MARKETING.—The florets are the parts required by the perfumery trade. Dry according to the general directions for blossoms.

Crocus, Autumn (*Colchicum autumnale*. Syns. COLCHICUM, MEADOW SAFFRON. Nat. Ord. Liliaceæ), *B.P. & H.*—A specific for gout, valuable as a diuretic and purgative.

DESCRIPTION.—A pale mauve crocus which blooms in the autumn without leaves.

CULTIVATION.—One of the most important of the pharmacopœial plants, but highly poisonous. (See precautions in handling under ACONITE.) It can be grown from seed with a view to planting out in damp, marshy, or meadow ground, where there is no risk to grazing animals. It may be sown in the open on a bed of prepared soil any time from May onwards, and very lightly covered. It may not sprout until the following spring. The two-year-old plants should be set when transplanted about 3 ins. apart, unless they are dotted about the ground in irregular order. The Colchicum exhibits first its leaves only, and when these completely die down, the purplish-pink blossom appears in August or Sep-

[1] See also separate article on this flower.—EDITOR.

tember. The locality of the flowers should be carefully noted in order to lift the corms later. If grown from "corms," plant these in groups of twelve, setting them 8 ins. deep. Allow them to establish themselves for a few years.

MARKETING.—The roots of the plant go very deeply into the soil and often go in crooked, so that they require to be taken up by means of a bulb lifter, unless the whole plantation is ploughed. The "corms" should be collected from plants of two years' growth, and the seed, when the capsules are ripe. The market for both is steady and worth meeting. The seed requires drying, and the corms, divested first of their outer layers, are sliced, and dried in artificial heat. Chemists should be asked to show a specimen of the commercial article, and B.P. description consulted.

Crocus, Saffron (*Crocus sativus*. Nat. Ord. Iridaceæ), *B.P.C. & H.*—A drug used for colouring purposes is obtained from this plant, popularly known as SAFFRON.

DESCRIPTION.—A purple spring flowering crocus.

CULTIVATION AND MARKETING.—Plant the "corms" in November or some seed in the spring. The yellow stigma is the part required, but such an enormous acreage of crocuses would be necessary from which to derive even a few ounces of the dry drug, that saffron culture cannot be recommended to the would-be herb grower. The plant must not be confused with Autumn Crocus, or Meadow Saffron, nor with the Safflower.

Dandelion (*Taraxacum officinale*. Nat. Ord. Compositæ), *B.P. & H.*—This is useful as a diuretic, laxative, and tonic. It is too well known to need description. Its culture as a salading is dealt with in the article on *SALAD PLANTS*.

CULTIVATION.—Dandelion root is much used in official British medicine, and although the plant is so ubiquitous and so common it is not one which can be left wholly to collectors. In the first place the root is wanted every year in great quantity, and in the second, this root should be of good size and shape and growth, unlike the inferior or much forked specimens derived from ground unfavourable to their development. Where Dandelion can be collected from rich, moist pastures, the root is probably as good as that from cultivated gardens, but the little wayside roots extracted from stony or poor waste ground are worth nothing. In proportion as good ground is now being brought under cultivation, the natural preserves of marketable Dandelion will grow less and less, and the herb will require more and more to be cultivated. Tap roots should be as uniform in size and shape as possible. They tend to fork from two causes—either through encountering stones or other obstacles in their descent through the soil, or because this is too dry at a depth, and whatever moisture there is, is to be found nearer the surface. The first requisite, then, for fine Dandelion culture is well and deeply prepared moist ground. A good loam or clay is best. About 4 lb. of seed per acre are drilled in rows a foot apart, and the crop requires to be diligently weeded. As only the roots are needed, growers must prevent the formation and spread of the seed by cutting down the flower-heads as they appear. (These, indeed, can be marketed, and fetch about 10d. per lb. dried.)

MARKETING.—The roots are dug in the autumn of the second year. The yield should average 4–5 tons of fresh root per acre, and the price 10s.6d. per cwt. for these undried. The roots should be dug in dry weather, and they had better not go through any process of washing for fear of mould or mildew making its appearance as they are stored. Growers who specialise on other root-crops such as Burdock, Chicory, and Valerian, would probably undertake the drying also of this crop, since what may be described as the "technique" of the process is much the same in all cases.

Deadly Nightshade.—See BELLADONNA in this article.

Dill (*Peucedanum graveolens*. Nat. Ord. Umbelliferæ), *B.P. & H.*—This is used for aromatic and carminative purposes.

DESCRIPTION.—An annual somewhat like Fennel in appearance but with smaller leaves. Its well-known preparation—DILL WATER—is largely used for soothing restless infants.

CULTIVATION AND MARKETING.—See notes on CARAWAY, CORIANDER, FENNEL, LINSEED, and SUNFLOWER for scope and general management. This crop is easily grown and may pay well as time goes on. Cultivation is similar to that of spring oats, about 10 lb. of seed being drilled to

the acre, and careful attention given to the destruction of weeds. The plants require much watching as the time for harvesting approaches, since the fruits do not all mature at once, but in succession. Consequently, the first to ripen fall, and waste, unless immediate steps are taken. The crop should be mown down early, and the unripe heads allowed to mature later. In dry periods cutting is best done in early morning or late evening. The loose sheaves are built into small stacks of about twenty sheaves tied together. In hot weather thrashing may be done in the field. The crop is considered rather exhaustive of soil fertility, so that it should not be sown two years in succession on the same ground unless this has been well manured in the meantime. The yield of Dill fruit should be about 7 cwt. per acre.

Dock (*Rumex aquaticus* and *R. crispus*. Nat. Ord. Polygonaceæ). — A plant finding application as an alterative and tonic, and too well known to need description.

MARKETING.—Two or three species of Dock have a value in herbalist medicine. The root is the part required.

Dog Rose.—See under ROSE, FRENCH.

Elder (*Sambucus nigra*. Nat. Ord. Caprifoliaceæ), *S.*—A plant used for aromatic, alterative, aperient, and emollient purposes, etc. Both the berries and flowers are required.

MARKETING.—This is a herbal crop for the collector rather than the grower. The flowers are dried on the umbels. Consult any good Collector's manual.

Elecampane (*Inula Helenium*. Nat. Ord. Compositæ), *B.P.C. & H.*—This herb is used as an expectorant, carminative, diaphoretic, and tonic.

DESCRIPTION.—A stout perennial with large, bright yellow, ragged flower-heads, solitary at the top of the stems. It is found occasionally in the wild state in damp meadows or shady spots, but possibly only as a naturalised escape from cultivation. It is grown in materia medica gardens for the sake of the root, which is the part required.

CULTIVATION.—Seed may be sown on fine beds in the spring and transplanted later to the field, but these do not flower the first year. The usual method of propagation is by the division of old roots. Elecampane will grow in almost any soil, preferably a clayey loam, but the ground must be deeply dug or ploughed and well prepared before planting. A moist, shady locality will best meet its requirements. The offsets taken from the old roots, with a "bud" or "eye" to each, should be planted in the autumn about 18 ins. apart, in rows 2–3 ft. asunder. A proportion of such pieces of root may be kept in gentle heat under glass throughout the winter, with the object of raising a reserve stock of plants. The seedlings will not require thinning out, but they must be kept weed free.

MARKETING.—Dig the roots in the spring or autumn of the second year. They should be thick and spindle shaped. An acre of ground may yield a ton of dry root, and this should fetch a price of about 7d. per lb. The crop requires to undergo a careful process of washing, slicing, and drying. Elecampane is used in liqueur distilleries and is largely grown on the Continent for medicinal purposes as well as those of the confectionery trade.

Erigeron (*Erigeron canadensis*. Syn. CANADIAN FLEABANE. Nat. Ord. Compositæ), *B.P.C. & H.*—This is useful as a tonic, diuretic, and astringent. See also article on *ERIGERON*.

DESCRIPTION. — An erect, tall branched plant with yellowish heads and purplish-white ray florets.

CULTIVATION.—Plant in November or March in any good soil in sunny spot.

MARKETING.—The whole herb is required. This should be dried when coming into blossom. There is a demand for this variety of Fleabane, but a very slight one for the COMMON FLEABANE (*Pulicaria dysenterica*), often supplied in mistake.

Eyebright (*Euphrasia officinalis*. Nat. Ord. Scrophulariaceæ).

DESCRIPTION.—A charming little heath or downside plant a few inches in height supposed to be partially parasitic on the roots of grasses. It is worth the collector's attention.

MARKETING.—The whole herb, for which there is a steady demand, is picked when in flower and dried.

Fennel (*Foeniculum dulce*. Nat. Ord. Umbelliferæ), *B.P. & H.*—This is used as an aromatic and carminative.

DESCRIPTION.—A very well-known tall feathery herb with wide-spread umbels of tiny yellow flowers.

CULTIVATION.—Fennel likes plenty of sun, and will succeed on land dry and stony enough to be suited to little

else, but does best on a rich, stiffish soil, well prepared according to ordinary horticultural methods. It requires a warm genial situation. From 4½ to 5 lb. of seed are needed per acre. It should be sown in the spring in drills 3 ft. apart. See also notes on the umbelliferous crops generally under CARAWAY, DILL, and CORIANDER.

MARKETING.—A crop should be obtained averaging 15 cwt. per acre. The crop is cut or scythed down before the fruits are fully ripe. The "seed" is graded according to size and should not be "dirty," *i.e.* brown, or weather and soil stained. This detracts entirely from its value. Collectors of the wild herb should bear this point in mind.

Fern (Male) (*Dryopteris Filix-mas.* Nat. Ord. Filices), *B.P. & H.* — A drug used as an anthelmintic, and an important pharmacopœial plant.

CULTIVATION.—Would-be growers of Male Fern must be careful in transplanting specimens from the wild, or in collecting spores for sowing, to identify the correct fern, since this species may easily be mistaken by the amateur among others which bear a general likeness to it. The kidney shape of the spore case, and the number of points in any transverse section of "root" or leaf base, are the determining features, but if any doubt is felt on this head the only safe plan would be to obtain stock for propagating from some reliable firm.

The plant is quite common in this country, and grows freely in moist, sheltered situations. It would be worth the while of those who have a stretch of woodland, on some portion perhaps of an estate or fair-sized farm, to encourage a plantation there of Male Fern. The spores should be sown in autumn in damp, shady spots, preferably on the banks of streams. The sowings should be left untouched for a few years to mature and increase, and later there would be a steady market for the yield. It is not, indeed, a fern which first springs from the spore; several years must pass before "rhizome" of sufficient size can be dug from the young plants, and the better grown and more established these are, the finer the product.

MARKETING.—The "rhizome," or root, a brown scaly mass covered with a tangle of chaff, leaf stalks, and fibres, is dug in late autumn, divested of all this dead or extraneous matter, and carefully dried. Harvesters of Male Fern root should make inquiries as to the current prices and market for that season, as the drug deteriorates in storage and should not be used after a year.

Feverfew (*Chrysanthemum Parthenium* or *Matricaria Parthenium.* Nat. Ord. Compositæ).

DESCRIPTION.—A well-known wild perennial, with yellow centres to its white petalled flowers.

MARKETING.—Dry the leaves according to the usual directions for herbaceous material.

Flax (*Linum usitatissimum.* Nat. Ord. Linaceæ).—This is the source of linseed.

DESCRIPTION. — The blue-flowered flax. A crop (if grown on commercial scale) for the farmer, as it requires considerable acreage.

PURGING FLAX (*Linum Catharticum*).—This has a white blossom. Both these plants are grown either for seed *or* fibre, but they cannot profitably yield the two products.

Fleabane.—See ERIGERON above.

Foxglove[1] (*Digitalis purpurea.* Nat. Ord. Scrophulariaceæ) *B.P. & H.*—This herb is used for making a powerful cardiac tonic; also as a diuretic; and is the source of an important alkaloid. It is one of the principal pharmacopœial plants.

COLLECTION.—In 1914, and during the early days of the Great War, the public were advised to grow Foxglove by way of combating the anticipated shortage of the imported drug. But Mr. E. M. Holmes soon pointed out that the plant grew wild in such quantity all over England where the soil happened to suit it, that if only proper facilities for its collection and drying could be arranged, there would be no occasion to cultivate the herb, but rather indeed to organise for making it one of our national exports! The Herb Growing Associations no longer require their members to grow Foxglove, but only to collect the leaf in the proper season, *i.e.* just before the blossoming spike comes to perfection. It may be as well to point out that the species *Digitalis purpurea*—the well-known "purple" foxglove—often exhibits white to yellow blossom. The leaves from these should be gathered, as they are identical with those from the purple-

[1] For details of garden culture and species not named here reference to our separate article on *FOXGLOVE* should be made.—EDITOR.

flowered specimens. The flowers of none are required.

CULTIVATION.—Foxglove is often grown in gardens for the sake of its showy blooms. It requires a well-drained loose soil, rich in leaf-mould, on silicious or slaty ground; and a moderate amount only of sun, preferring, indeed, shady spots in the woodland. It can be raised from seed. The plant is biennial and sends up only a rosette of leaves the first year; it will thus spread and propagate itself.

MARKETING.—Great care should be exercised in gathering and drying the leaves, all those in any way defective, spotted, or eaten, being rejected. The product should retain a good colour or it will be unsaleable. Dry the leaves quickly, soon after picking, in shade, a few at a time; not altogether in a moist or unmanageable heap. The price for the dried leaf varies according to quality of sample from 4d. to 1s. 4d. per lb., or 10s. 6d. per cwt.

Garlic.—See separate article, also under SHALLOT in present article.

Gentian[1] (*Gentiana lutea.* Nat. Ord. Gentianaceæ), *B.P.*—The root is used as an infusion (bitter tonic), and extract as basis for pill massing.

DESCRIPTION AND CULTIVATION.—The Gentian used in medicine is not generally grown in this country, and it is to be doubted whether an attempt to do so would meet with commercial success. The more familiar *Gentiana acaulis* of the rock garden is not the required species. *Gentiana lutea* has large ovate parallel-ribbed leaves much like those of the genus *VERATRUM*, on which we devote a separate article. These plants require moisture and good drainage; they do well in rockwork and in shady borders. (*Gentiana purpurea, G. pannonica,* and *G. punctata* are sometimes seen in commerce.)

MARKETING. — The rhizomes and roots are collected in the autumn and dried fairly quickly so as to avoid fermentation. Slow drying, however, secures a better colour.

German Chamomile. — See under CHAMOMILE.

Heartsease.—See under VIOLET.

Hemlock (*Conium maculatum.* Nat. Ord. Umbelliferæ), *B.P.C. & H.*—An intensely poisonous herb (see precautions to be taken under ACONITE), and the source of an important alkaloid. A cardiac remedy.

DESCRIPTION.—Hemlock grows wild all over England. It is a tall branching biennial plant found in hedgerows, with leaves much like those of the familiar hedge Parsley, and umbels of crowded but inconspicuous greenish-white flowers. The harvest is taken when the plant is in both fruit and flower during its second season. In cool, sheltered situations Hemlock may attain twice the height to which it grows in the sun or merely by the roadside. It can be very easily recognised and distinguished from the host of other umbelliferous "weeds" so much like it—superficially—by two signs, the distinct dark purple blotching all up and down its stout, hairless, furrowed stem, and the strong mousy, fœtid smell of its crushed leaves.

CULTIVATION AND MARKETING.—Hemlock can be grown from seed sown in shallow drills 3 ft. apart in the spring. The seedling plants, which only form small dense bushes of leaves the first year, require thinning to about 13 ins. apart. They need a good deal of watering in dry weather or on light soil. In the second year the leaves are stripped when the herb has shot up to about 4 ft. in height, and is just coming into blossom. Like the yields of all other herbaceous plants Hemlock should be consigned to the buyer without delay, or dried immediately. The seed is collected before it ripens on the plant, and allowed to mature afterwards. The entire flower-heads or "umbels" are picked, and the "seed" (more correctly the fruit) is thrashed out when these are ripe and dry.

Henbane (*Hyoscyamus niger.* Nat. Ord. Solanaceæ), *B.P. & H.*—This highly poisonous plant is used as a narcotic, anodyne, and sedative. It is the source of valuable alkaloids.

DESCRIPTION.—Henbane occurs in two varieties, annual and biennial. The former is required in far less quantity than the latter and is seldom cultivated intentionally. The leaves, flowering tops of branches, and the seeds all command a fairly steady and satisfactory price in the drug market. The plant is found growing wild in waste places, on rubbish heaps, and in sandy localities near the sea, but it is not particularly common. It is an unattractive but very unmistakable herb, with large viscid downy leaves,

[1] For rock garden culture and other species our article on *GENTIANA* should be consulted.—EDITOR

drooping in pairs along the coarse branching stems, funnel-shaped, drab-coloured flowers with purple veins and a dark centre, succeeded by capsular hairy fruits. The whole herb has a rank narcotic smell.

CULTIVATION.—Henbane culture is not a matter for the amateur. The plant is one of the most erratic, unreliable, but remunerative crops upon which the would-be herb specialist might embark. [All the expert literature or advice to be obtained on Henbane Culture should be consulted, and rather than take up the quantity of space necessary to do justice to the plant we prefer to advise readers to consult Miss Teetgen's *Profitable Herb Growing and Collecting* (Country Life Ltd.) or other similar works.—EDITOR.]

MARKETING.—The leaves are the part chiefly required. The best are obtained from plants in their second year. The flowering tops are also in demand, as also are the autumnal leaves of first year plants. The crop should be despatched at once, as it will not keep.

Hollyhock (*Althaea rosea*. Nat. Ord. Malvaceæ), *S.* — A herb used as a demulcent and colouring agent. See separate article for details on growing gardening Hollyhocks in their numerous varieties.

CULTIVATION AND MARKETING. — Hollyhock is too well known to need description. The plant is grown in materia medica gardens for the sake of its deep red blossoms. These should be picked from the spike as they severally come to perfection in August, freed from the calyx, and carefully dried so as to retain a good colour. The garden Hollyhock is not a native wild British plant. It is a perennial Mediterranean species, and is grown from seed sown in deep rich soil, in the open, from November to March. It flowers from July to October, the single forms being more easily cultivated than doubles. As the plants may attain a great height they require careful staking. They are subject to an apparently incurable disease which destroys the leaves, and will succumb to damp and ungenial surroundings. The only remedy is to make fresh sowings.

Holy Thistle (*Carduus benedictus*. Syns. BLESSED THISTLE, MILK THISTLE, MARY'S THISTLE. Nat. Ord. Compositæ), *H.*—A herb used as a tonic, stimulant, diaphoretic, and emetic.

DESCRIPTION AND CULTIVATION.—Blessed Thistle is a biennial but not a native British plant, though it can be grown successfully in this country in a warm and genial situation. The richer the soil, and the better prepared, the larger the yield of herb. It can be raised from seed sown very thinly as early in the spring as possible up to the middle of June; this requires to be lightly covered with soil. The seedlings must be thinned out to about 18 ins. apart, and kept clear of weeds. Seed should only be obtained through a thoroughly reliable channel, or the plants will not be true to medicinal strain.

MARKETING.—The crop is harvested as soon as the blossom begins to appear. The average yield per acre should be from 3 to 5 tons, and the average price per cwt. is about 38s.

Horse Mint.—See AMERICAN HORSE MINT in article on *POTHERBS*.

Horseradish (*Cochlearia Armoracia*. Nat. Ord. Cruciferæ), *B.P. & H.*—A herb used as a diuretic, stimulant, and sialagogue. See also article on *HORSE-RADISH*.

DESCRIPTION.—A familiar kitchen garden plant which grows like a weed when once established.

CULTIVATION.—All it requires is a deep poorish soil. Propagation is from crowns set in a well-manured trench about 18 ins. deep.

MARKETING.—The root, dug from two-year-old plants, is required, and it must be well dried. *Carefully distinguish it from Aconite root.*

Hyssop.—See article on *POTHERBS*.

Juniper (*Juniperus communis*. Nat. Ord. Auracariaceæ), *H.*—Juniper oil is extracted from the Juniper berry, and this is used as a diuretic, aromatic, and stimulant. It is a fruit for the "Collector" rather than the herb-grower.

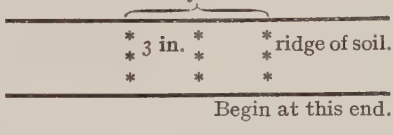
Lavender.—See article on *POTHERBS*.

Lily of the Valley[1] (*Convallaria majalis*. Nat. Ord. Liliaceæ), *H.*—A plant used as a cardiac remedy.

DESCRIPTION AND CULTIVATION.—A well-known perennial plant with a creeping rhizome root, found in the wild state growing in cool places on rich but light soil. It is, however, much cultivated in gardens, and ground is always devoted to it in herb plantations.

[1] The garden culture of this plant is described in a separate article entitled *LILY OF THE VALLEY*.—EDITOR.

Lily of the Valley is grown from "crowns" (to be obtained either from wild specimens in the autumn, or through any reputable firm of florists and seedsmen). These are set 6 ins. apart in rich soil and a shady position, but not under trees, from October to November. They will require replanting after five or six years, but in the meantime if not allowed to overcrowd each other, the plants will have yielded plenty of flower scapes, since they blossom all through May and June. See also directions for Violet and Heartsease Culture.



MARKETING.—The part required in commerce is the entire flowering stem. The flowers are dried on the stem, and should retain as much of their whiteness as possible. It commands a good price, averaging about 5s. 6d. per lb. in a dry state.

Linseed.—See under FLAX.

Liquorice (*Glycyrrhiza glabra.* Nat. Ord. Leguminosæ), *B.P. & H.*—This is used as a laxative, and flavouring agent.

DESCRIPTION.—Liquorice leaves are compound in character. Its flowers are mauve and similar to pea flowers, though smaller. They drop so quickly—especially in wet seasons—or appear so late, and are so inconspicuous that they often escape the attention even of those familiar with a liquorice field. Pods are rarely formed and never contain more than one or two seeds. The roots range from 2 ft. to 10 ft. in length.

CULTIVATION.—Liquorice is not a native British plant, nor—like the majority of the plants we are considering—is it a wild herb. It is, however, an herbaceous perennial, the chief difficulty in its cultivation being the great length of its root. This last is the part required in commerce, and it requires to be dug up without breaking or injury. Liquorice can be grown quite easily in this country: it is propagated by the division of the 4-year-old roots, and not from seed. The plant requires no less a depth of rich loam than 2½ ft., preferably resting on a well-drained subsoil of marl. The ground upon which it is proposed to grow liquorice should be divided into four equal portions, and so planted that every year the liquorice upon one or another of these comes to maturity and is lifted. It is prepared by careful trenching and manuring, and previous to the setting of the "buds" should be in a fine condition of tilth. These "buds," called respectively "crown buds" and "runner buds" from the portions of the root from which they are derived, are planted in the soil in threes at the rate of nine to the yard, and are set about 3 ins. apart. The soil itself is previously cast into ridges endways to the sun, the ridge (or "grip") and trench (or "liquorice valley") together measuring a yard across. Each "bud" consists of about 6 ins. of root, and is set half in and half out of the soil by means of a steel-shod dibber, and is then well and firmly earthed down. The arrangement of "buds," originally thus:

is altered when the row is complete, by the resetting of the centre "bud" thus:

"Runner buds" and "crown buds" can be used together with judicious arrangement and alternation in setting, in the proportion of half and half, or one-third of the former to two-thirds of the latter. Catch crops of ordinary vegetables can be grown in the trenches between the rows of liquorice for the first two years, but after that time the practice cannot be continued as the plants then become too tall and bushy and monopolise the space.

Every year the foliage of the liquorice plant dies down, and the withered stalks should presently be cut away as close to the ground as possible without injury to the dormant buds.

MARKETING.—When, however, the plants on any given section of the plot reach the age of four years, the roots are ready for harvesting. First the foliage (*only of that particular plot, and only sufficient for each day's lifting operations*) is mown down, the trenches opened as deeply as may be found necessary, after which the roots are carefully taken out. These are then "horned," *i.e.* shorn of the remaining

leaf stalk (care has to be taken to avoid excessive "bleeding"), and finally cut away from the crown and prepared for market. The subsidiary roots are not detached, but the "fibre" is stripped and sold separately from the root itself. The crowns remaining are then paired and divided for resetting to increase the stock. The plant should be discouraged from forming too many runners, as it has a tendency to do in light soil, since this causes deterioration in the quality of the root. Runners can be cut back when cleaning the ground, generally in the winter. The runners of the four-year-old plants are used for setting again as buds, new growth taking place upwards and downwards from any given growing point on a length of about 6 ins. The crown buds should not be divided up too much, it being preferable to raise a sturdy plant from one with two or three branches than a weakly one from an over-pared stock.

Cultivation of liquorice in shallow soil would probably obviate a good deal of the laborious deep digging which at present makes the crop so onerous a one to undertake. In shallow soil the root would either thicken and shorten, or turn, and run along on the top of the sub-soil, so that it could be thrown out, not by hand, but with horse labour and a scarifier. The root should be about the thickness of a fair-sized carrot: it may be 4 ft. to even 10 ft. long.

The yield of liquorice root should be about 10 tons per acre. The price of English root has greatly recovered since 1914, so this is a great inducement to cultivate it.

Male Fern.—See FERN (MALE).

Mallow (*Althaea officinalis*. Nat. Ord. Malvaceæ), *B.P.C.* & *H.*—This is used as an emollient and demulcent. It is similar to HOLLYHOCK (*q.v.*), and may be grown and marketed in the same manner.

MARSH MALLOW (*Malva sylvestris*, Nat. Ord. Malvaceæ) must be distinguished from the common Mallow by the nature of the places where it grows, its larger "habit" generally, and its beautiful mauve-pink blossoms. It is found in dykes, ditches, damp meadows, salt marshes, and near the sea, but is of very local occurrence. It flowers from August to September, and is a perennial.

CULTIVATION.—The golden rule in this and all other wild-herb cultivation is to imitate as far as possible the natural conditions under which the plant is found. The roots are thick, long, and tapering. They bend easily, are whitish-yellow outside, white and fibrous within, and abound in mucilaginous juice. It is these roots which are chiefly required in medicine. The herb can be raised from seed sown in spring, and also from cuttings. Offsets from the roots carefully divided in autumn when the annual growth has died down, will grow of their own accord. They should be planted about 2 ft. apart, and could well be cultivated on waste or unused ground in any damp locality. They should be dug in autumn from plants not less than two years old, and dried, decorticated, and otherwise prepared for market according to the usual methods. Marsh Mallow leaves should be picked and dried in August; the flowers with the calyx attached being gathered when just expanding, and so dried—in a current of dry air—out of the sun, as to preserve the colour as much as possible.

Marigold (*Calendula officinalis*. Nat. Ord. Compositæ), *H.*—This is used as an antispasmodic, deobstruent, and diaphoretic.

CULTIVATION.—Marigold is grown from seed, and will succeed on a light sandy soil or a rich garden loam. It does well on a variety of soils. If sown at the end of August or in early September it flowers earlier than if held over to the early spring. It should be sown in drills 18 ins. apart, in an open situation, and the seedlings thinned to stand 2 ft. apart. The herb is an annual, but will re-seed itself, come up year after year, and spread profusely.

MARKETIN .—The parts required are the yellow ray florets of the blossoming head. These should be picked throughout the entire flowering season, and must be very carefully dried to retain a good bright colour. Mr. Holmes considers that "the commercial article might be much improved by growing a deep coloured variety, such as *Prince of Orange*." The petals fetch about 1s. 6d. per lb. dried, and, although it will be obvious how great a mass of florets will be requisite to produce this weight of dry product, when it is remembered how easy Marigold is to grow, how profusely it blossoms, and how long the season lasts, the collection would probably be worth while, especially considering the demand is not a problematical one, but quite constant.

Marjoram.—See article on *POTHERBS*.

Meadow Saffron.—See under CROCUS, SAFFRON.

Melilot (*Melilotus officinalis*. Nat. Ord. Leguminosæ).

DESCRIPTION.—This forms a dainty feathery bush bearing white or yellow racemes of minute papilionaceous blossoms. It grows wild in waste places, but is not common, and thus it should be protected from extermination by indiscriminating collectors.

MARKETING.—The floweringbranches gathered in July or August are required, but all woody portions should be rejected.

Mint.—See article on *POTHERBS*.

Mountain Flax.—See under FLAX.

Mugwort (*Artemisia vulgaris*. Nat. Ord. Compositæ), *H.*—This is used as a diaphoretic, emmenagogue, and nervine.

DESCRIPTION.—Mugwort and Wormwood (see WORMWOOD) are wild plants, related to Southernwood (see under SOUTHERNWOOD) and TARRAGON (see under *POTHERBS*).

CULTIVATION AND MARKETING.—The culture for all is along similar lines, and very simple. The plants are easily propagated from cuttings inserted in dry, sunny, open situations. The parts required are the "tops" or slender young branches.

Mullein [1] (*Verbascum Thapsus*. Syns. BLANKET HERB and GREAT MULLEIN. Nat. Ord. Scrophulariaceæ), *H.*—This is of value as an astringent, demulcent, emollient, and gentle anodyne.

DESCRIPTION.—A tall handsome biennial plant with leaves of a thick woolly texture somewhat like those of Foxglove, and a single spike of close-packed yellow flowers which open one after another.

CULTIVATION.—Mullein is grown from seed sown in well-drained loose soil, rich in vegetable humus. It requires a fairly sunny situation but a moderate amount of shade. Seedlings will bear transplanting especially in damp weather, so that a reserve of these can be raised to fill up gaps in the field. During the first year the plant produces only a dense rosette of leaves, but in the second year their flowering spikes and tall herbaceous stems may attain a height of 7 ft. They are fairly easy to raise, but the leaves are subject to disease.

[1] For Garden Culture and Species our article on *MULLEIN* should be consulted.—EDITOR.

MARKETING.—Mullein is found in fair quantity, but would benefit from cultivation and study. There are six British species of Mullein, the one required in medicine being GREAT MULLEIN (*Verbascum Thapsus*), which bears a single tall spike of yellow blossoms opening one after another.

These flowers should be picked from the spike as they appear, freed from the calyx, and so dried as to avoid the process of fermentation which turns them brown and ruins them for the market. The woolly, blankety leaves are also gathered just as the plant flowers, and the roots are dug in the autumn of the second year.

Mustard (*Brassica alba* and *B. nigra*. Nat. Ord. Cruciferæ), *B.P. & H.*—This is used as a source of a powerful vesicating oil.

CULTIVATION.—This should be carried out on a farming scale where possible. Sow the seed in drills from the middle of March to the end of August. The drills should be 12–15 ins. apart, and the seedlings should be thinned out to about 6 ins. They require careful weeding.

MARKETING.—The seed is required, and to obtain it the crop must be cut when the seed is nearly ripe and well thrashed.

Onion.—See note under SHALLOT, and also article on *ONION* farther on in this book.

Opium Poppy (*Papaver somniferum*. Nat. Ord. Papaveraceæ), *B.P. & H.*—This is a source of opium and of many important alkaloids. The preparations from it are anodyne and narcotic.

CULTIVATION.—This is an annual plant, the white variety of which is required. It does well in a somewhat stiff soil in a sunny situation where moisture is not lacking. The crop is an uncertain one from a cultural point of view, but sure of a certain and remunerative market if it can be harvested in fair condition and quantity. [The instructions in the Board of Agriculture Leaflet, No. 288, should be carefully followed in growing this plant. We have no space to quote them here.]

MARKETING.—The capsules or seed-vessels should be gathered in September and carefully dried. They are sold by the thousand, and the price paid varies with the size of the capsules.

Orris Root (*Iris*. Nat. Ord. Iridaceæ).—Orris is a drug derived from the rhizomes of various species of Iris grown

abroad. It is not recommended to the would-be English cultivator.

Parsley.—See separate article.

Parsley Piert (*Alchemilla arvensis*. Syn. PARSLEY BREAKSTONE. Nat. Ord. Rosaceæ), *H.*—This is used as a diuretic and refrigerant. It is said to be of great efficiency in stone.

DESCRIPTION.—An insignificant little "weed" of ploughed lands, closely allied to the somewhat better known Lady's Mantle. It appears in grey-green roundish and spreading tufts, and bears very inconspicuous green flowers in the axils of the leaves. The herb is described as common by botanical writers, but it seems to be often conspicuous by its absence even in likely places. It is in steady demand, and might therefore repay, not perhaps for cultivation, but for encouragement in waste and fallow places by those who have the overseeing of farms.

MARKETING. — Shake clear from earth, cut away the root, and dry in shade.

Pasque Flower (*Anemone Pulsatilla*. Syn. ANEMONE. Nat. Ord. Ranunculaceæ).—This is prescribed in cases of heartburn, waterbrash, biliousness, etc.

DESCRIPTION.—The Pasque Flower —a beautiful plant bearing violet blossom rather like a very large anemone—grows wild in this country in high-lying pasturages, but it is very uncommon. It could be cultivated for commercial purposes on a limited scale.

CULTIVATION.—Seeds should be sown as soon as they are ripe. They require to be thoroughly separated by well mixing with sand or dry soil or their long feathery awns prevent satisfactory sowing. They may be sown outside from April to August in a lightly shaded seed-bed very lightly covered with soil, made firm, watered lightly, and kept quite shaded from the sun until the seedlings appear. The entire herb is required and should be cut when just coming into flower. It should not be largely grown unless definite orders can be obtained. The plant is perennial and is mentioned under rock garden species in our article on *ANEMONE*.

Poppy.—See under OPIUM POPPY.

Prunella (*Prunella vulgaris*. Syn. SELF-HEAL. Nat. Ord. Labiatæ), *S.*—This herb is used as an astringent.

DESCRIPTION.—A ubiquitous little herb a few inches high occurring everywhere in meadows. It has an elongated head of whorled purplish corollas of the typical labiate type; but unlike some of the plants of this group, Prunella, when once recognised, can never be confused with others of the same order. It falls within the province of the collector, not of the grower.

MARKETING. — The whole herb, carefully dried, is required and has enjoyed a good reputation in the "natural" system of medicine, and is still in good demand among herbalists.

Raspberry.—See article on *BUSH FRUITS*. The young leaves from new canes containing a high percentage of tannin are required in herbal medicine.

Rose, French (*Rosa gallica*. Nat. Ord. Rosaceæ).—It is not proposed to enter any notes on rose culture here, since this is dealt with as a horticultural subject by an expert in separate articles. We may remark, however, that the petals of any deep crimson varieties of roses have a value in the drug market, those of the French rose being officinal in the B.P. The rules for the drying of rose petals are similar to those for all blossoms. The petals should be pinched from the flower at the moment when the bud is about to expand—in a fragrant, crumpled, conical mass—and should by no means be taken merely when the blossom is "over" and fallen. They require careful drying in shade, in natural heat, and should be repeatedly turned over to prevent them sticking or fermenting. They should not, for medicinal purposes, be made into pot-pourri. The demand for rose petals may be a fairly constant one, but it is not large.

Rosemary. — See article on *POTHERBS*.

Rue.—See article on *POTHERBS*.

Saffron.—See CROCUS, SAFFRON.

Sage.—See article on *POTHERBS*.

Sanicle (*Sanicula europaea*. Nat. Ord. Umbelliferæ).—This is useful for many herbalist purposes, and is often used as a vulnerary.

DESCRIPTION.—Sanicle is one of the most charming of the smaller herbs. It is a slender, dainty plant found in shady woods with small heads of white blossom like little stray tufts of cotton-wool. The name indicates in what medicinal repute Sanicle used to be held by the old herbalists.

CULTIVATION.—It should be protected and encouraged to spread in

the wild state where found, but is hardly worthy of garden culture.

MARKETING.—Gather the whole herb in August and dry carefully.

Savory.—See article on *POTHERBS*.

Shallot.—See separate article. It may, however, be remarked here that the juice of garlic, onion, shallot, and allied plants has greatly come into estimation of late years—especially on the Continent, where the peculiar scent of it is not resented—as an antiseptic lotion and irrigant for wounds.

Skullcap (*Scutellaria galericulata*. Nat. Ord. Labiatæ).—This is used as a nervine in epilepsy.

DESCRIPTION.—The Common and Lesser Skullcaps are both English "weeds" with characteristic labiate flowers, which have some value in herbalist practice, and are sought by herb gatherers, possessing the same properties as *S. lateriflora*, an American species, although in a lesser degree. English horticultural firms will supply stocks of two or three species of Scutellaria. They are hardy plants suitable for growth about a rockery. The above named is highly esteemed by medical men who have tested its use, and is not unlikely to gain further recognition. Its culture is on the same lines as that of the labiate potherbs.

Southernwood (*Artemisia Abrotanum*. Nat. Ord. Compositæ).—This is used as an infusion and stimulant.

CULTIVATION.—See also under TARRAGON in article on *POTHERBS*. Southernwood is readily propagated by cuttings and will thrive in any free, light soil. It is a grey-green scented bushy perennial plant of which the "tops" are required.

Sunflower (*Helianthus annuus*. Nat. Ord. Compositæ), *H*.—This is grown for seed and oil.

DESCRIPTION.—An annual variety of Sunflower forming very large heads with enormous seed disks.

CULTIVATION.—It is grown from seed, set thinly in boxes under glass in March. Any ordinary soil or compost similar to that used for cucumbers or marrows will suit the Sunflower. The seedlings are planted out early in May, after the danger of frost is over, and should be set 2 ft. apart in rows 3 ft. asunder. The soil should have been previously well dug and manured, applying dung at the rate of about 3 cwt. of ordinary farmyard manure per rod, and giving an application of 1½ oz. of superphosphate of lime per square yard before or at the time of planting. This will encourage the seed to mature early. Staking will be required especially in exposed and sunny positions, when they form very heavy heads of blossom. Seed is required at the rate of 1 oz. to 8 rods, care being taken to obtain that of the annual Sunflower only.

MARKETING.—The seed should be allowed to mature on the plant if possible, but (*a*) if the weather is unfavourable, (*b*) if the heads are much exposed to the depredations of birds, and (*c*) if the seeds are liable to be much shaken out, the flowers should be cut in late autumn when the seeds are nearing maturity, and dried on the shelves or the floor of any dry, warm building.

Sweet Basil.—See under BASIL in article on *POTHERBS*.

Sweet Marjoram.—See article on *POTHERBS*.

Sweet Sedge (*Acorus Calamus*. Nat. Ord. Araceæ).—This drug is aromatic and carminative.

DESCRIPTION.—An aquatic plant, to be carefully distinguished by the wavy edges of its sword-like leaves, and from their sweet scent when crushed, from plants of the Iris family.

CULTIVATION AND MARKETING.—The plant is easily propagated in very damp soil or on edges of streams by division of roots. The crowns are set in the same way as Horseradish and Liquorice, and the roots are harvested twelve months later by digging or turning out with the plough.

Sweet Violet.—See under VIOLET in this article.

Sweet Woodruff.—See under WOODRUFF in this article.

Tansy (*Tanacetum vulgare*. Nat. Ord. Compositæ), *S*.—This is used as a bitter tonic, emmenagogue, and diaphoretic.

DESCRIPTION.—This is one of the last wild flowers of the season. It is an upright, somewhat ragged plant found very generally all over the country, with much-cut leaves, and clusters of small rusty-brown coloured heads. Tansy need not be cultivated so much as preserved and encouraged in the localities where it is found. It used to be esteemed as a tea, and there is still sufficient herbal demand for the plant (although this fluctuates) for the collector's attention to be directed to it. The whole herb is cut in August and dried in the usual way.

Tarragon.—See article on *POTHERBS*.

Thistle.—See under HOLY THISTLE in this article.

Thorn Apple (*Datura Stramonium* and *D. tatula*. Nat. Ord. Solanaceæ), *B.P. & H.*—An important pharmacopœial plant, and source of alkaloids. It is used as a narcotic and antispasmodic.

DESCRIPTION.—Thorn Apple is a stout branching annual with long entire leaves and long white tubular flowers. It is somewhat rarely found in the wild state, but can be easily grown from seed. It thrives best in sunny open situations and in rich and rather heavy soils freely supplied with lime.

CULTIVATION.—Seed may be sown in the open early in the spring in drills 3 ft. apart, and the seedlings, which soon appear, require to be thinned out to at least 15–24 ins. apart, to allow for the spreading bushy growth which rapidly takes place. The plants will stand transplanting, so that a reserve might be kept to fill in gaps and failures here and there. As the flower-buds appear they should be pinched off to encourage a luxuriant crop of leaves, and even if the plant is chiefly being grown for seed it will be advisable to check the development of many capsules in order to obtain a few of first-rate size full of strong seed.

Thorn Apple is peculiarly subject to a certain insect pest which eats out the green substance of its stout somewhat fleshy leaves, leaving tracks of nothing but the transparent skin.

These small green grubs are to be found snugly nestling among the prominent branching of the veins on the underside of the leaves, and they appear very early in the plant's career. Probably the use of a good insectide spray [1]—unless it proved harmful to the herb itself—would do something to help matters at an early stage, but the writer has found the laborious method of cleansing the leaves by hand quite the most satisfactory. Once the plant is well ridded of the pest it seems not to be readily attacked again, probably because the time is then past when the leaves are succulent enough for the grub, or when the grub is no longer in that particular stage of its development to require them.

MARKETING.—The leaves are gathered when the plant is in full bloom. They can be picked by hand, or the entire crop may be mown down. Hand picking preserves the flowers and fruit, and the seed can be the more readily shaken from the dry gaping capsules when ripe for this thinning of the foliage. Yields of *dry* leaf at the rate of 1000 to 1500 lb. per acre may be obtained (*i.e.* five times that weight of fresh leaf is actually harvested).

If grown for seed the capsules should be harvested just before they are ripe, and allowed to dry, and open, and shed their masses of black reticulated seed on sheets of newspaper spread in the sun. Otherwise there is some danger of these capsules becoming mouldy on the plant. Growers must bear in mind that this plant is highly poisonous. See precautions under ACONITE in this article.

Valerian [2] (*Valeriana officinalis*. Syn. GREAT WILD VALERIAN. Nat. Ord. Valerianaceæ), *B.P. & H.*—An important pharmacopœial plant, well worth the grower's attention, which is used as a nervine, stimulant, antispasmodic, and tonic.

It must be carefully distinguished from the Red Valerian of the flower garden (*Centranthus ruber*), and from the various other species of wild Valerian and Centranthus.

DESCRIPTION.—A stout tallish plant with pinnate leaves consisting of numerous leaflets, and white or pinkish flowers, in a terminal rounded "cyme." It is a perennial, flowering from June to July, and is found in damp neglected spots, though it is not particularly common.

CULTIVATION.—Valerian may be grown from seed, or from the runners given off by older plants. The ground should previously be well dug and treated with farmyard manure. It must be fairly retentive of moisture, and be in a damp, shady locality or situated on the bank of a stream. The seed—to be obtained in autumn from fine wild specimens, or through seedsmen who understand the strain required—can be sown in the open from April to August. Seedlings must be

[1] Spray preferably with a strong soap and quassia infusion, followed by a drenching with pure water. Or one of the nicotine fluids or other leaf-eating-caterpillar destroyers advertised in reliable horticultural journals may be tried. In the case of medicinal herbs grown for their leafage, poisonous drenches (of arsenic or lead) must be avoided.

[2] For Garden Culture and Species see article on *VALERIANA*.—EDITOR.

pricked off and set in permanent quarters as soon as they attain a fair size. They need careful weeding, and must have abundance of liquid manure, and water. Plants grown from seed may not flower the first year, but will produce plenty of leaves. If blossom should appear it should be cut off to encourage the formation of good root or rhizome. The underground stems of Valerian give off slender runners from which new plants originate. The usual method of propagation is to transplant wild specimens, or to collect these daughter plants, setting them in prepared ground at a suitable distance apart, and treating them in the same way as seedlings.

MARKETING.—In September and October the plants are scythed down and the rhizomes are dug or ploughed out. These are then placed in troughs or boxes drilled with holes in a stream of running water, and well stirred, until thoroughly washed. They are next sliced and dried in artificial heat. The smaller rhizomes need not be sliced. The B.P. thus describes the commercial article as it should appear on the market after this process: "A short erect rhizome entire or sliced, dark yellowish-brown externally, and giving off numerous slender brittle roots 3–4 ins. long, of the same colour as the rhizome: rhizome and roots whitish or yellowish internally. The odour that is developed in the process of drying is strong, characteristic, and disagreeable; taste unpleasant, camphoraceous, and slightly bitter." Growers of Valerian would be well advised to undertake the process of curing on the spot, since they are then less dependent on an immediate market for sale, and the outfit required—washers, shed, coke stove, slicers, etc.—could be utilised for other herbal roots, such as aconite, belladonna, burdock, dandelion, dock, etc.

Violet (*Viola odorata*) and **Heartsease** (*Viola tricolor*. Nat. Ord. Violaceæ), *H.*—These herbs, the former a cultivated, sweet-scented species often found wild, but largely grown in gardens, and the latter found as a cornfield "weed," are both officinal in Homeopathy. The various violets and pansies used in perfumery and confectionery as well as in medicine are cultivated on a commercial scale at Stratford-on-Avon. The flower of the sweet-scented Violet is required as well as the leaves. It should be picked before it is in full bloom, and rapidly dried to retain as much colour as possible after being deprived of the calyx. The entire herb, Heartsease, is marketed.

CULTIVATION.—The violets are perennial herbs found very generally all over the country. They can be grown from seed or by transplanting *en masse* to suitable situations, where they spread, bloom, and multiply year after year, requiring little attention at the hands of the grower. The soil should be well prepared by digging in the first place, and mixed with fibrous loam, road grit, and farmyard manure. The position of the beds should be neither too sunny nor too shady. The young plants should be soaked in water during times of drought, when the sun is not too hot, and the herbs should generally be mulched when flowering with leaf-mould, moss litter, etc. The beds should be made afresh every few years.

Wintergreen (*Gaultheria procumbens*. Nat. Ord. Ericaceæ), *B.P. & H.*—This is the source of Oil of Gaultheria, used as an antirheumatic and anodyne. An important pharmacopœial plant.

DESCRIPTION.—This is a little procumbent ground-covering herb, with dark green leathery leaves, and bright red berries, allied to the Bearberry. Wintergreen is a source of a drug officinal in British medicine as well as in Homeopathy, which always commands a high price, so that the market for the herb is an assured and steady one. It is an herbaceous perennial plant with woody leaf-stems, not a native of this country, but an American plant, and must be distinguished from the five species of Pyrola or Wintergreen which grow wild in England.

CULTIVATION.—Wintergreen should be propagated from specimens found growing wild in their natural situation. Seeds expressed from the berries when ripe in the autumn will germinate if sown in suitable spots, *i.e.* in a grove, or under shade, or even under clumps of bushes, unless these trail upon the ground and completely exclude the light and air; but sets from the entire herb root easily and spread. Divided roots may be planted in woodland spots in the spring or autumn, about 6 ins. apart each way, in permanent beds. They will soon cover the entire ground. The soil requires a natural or artificial mixing to the depth of 4 ins. or more with good leaf-mould

or rich vegetable humus. The herb is gathered and dried in October.

Woodruff (*Asperula odorata*. Syn. SWEET WOODRUFF. Nat. Ord. Rubiaceæ).—This is useful as a diuretic and tonic.

DESCRIPTION.—This is a well-known beautiful little woodland herb, often grown in gardens. It could be marketed, if collected or gathered in sufficient quantity, without difficulty.

MARKETING.—Dry as for other herbs during the flowering season. The whole herb is required.

Wormwood (*Artemisia Absinthium*. Nat. Ord. Compositæ).—This is used as a bitter tonic and anthelmintic.

DESCRIPTION.—This is one of the plants, allied to Southernwood, Mugwort, and Tarragon, whose cultivation from seed or propagation by division of roots might advantageously be increased. The flowering "tops" are the parts required. Gather in August or throughout the blossoming season, and carefully dry.

Yarrow or **Milfoil** (*Achillea Millefolium*. Nat. Ord. Compositæ).—This is used as a diaphoretic, stimulant, and tonic.

DESCRIPTION.—A ubiquitous herb, the demand for which is such that the wild supply might be augmented by cultivation. It does well on light soil in open situations. Herb centres offer 1d. per lb. for fresh herb.—A. B. T.

MEDICINAL MANDRAKE (*Mandragora officinarum*).—See *MANDRAKE*.

MEDICINAL RHUBARB (*Rheum officinale*).—See *RHEUM*.

MEDICK.—See *MEDICAGO*.

MEDITERRANEAN CRESS. — See *MORISIA*.

MEDLARS.

These are grown as standards, and are esteemed by many. The large flat Dutch makes an umbrella-like tree, and is very pretty in blossom. *The Royal* and *Nottingham* grow upright. The latter is small but is produced in quantity. The flavour is briskly acid. *The Royal* is medium sized.

The trees are very hardy, and being worked upon the Thorn or Pear stocks, will grow anywhere. The fruit should hang on as long as possible and be stored in a cool place, where they "blet" (become soft and eatable) gradually. They make a fine jelly for game, etc., and a good jam for those who cannot eat sweet preserves. Planting is done as described in our notes on *APPLE*. They require no after care, but the fruits are larger where the boughs are kept fairly thin.—G. B.

See also *Pyrus germanica* in *TREES*.

MEGASEA.—Now included in the genus *SAXIFRAGA*.

MELANCHOLY THISTLE (*Cnicus heterophyllus*).—See *CNICUS*.

MELANDRIUM.—Now included in the genus *LYCHNIS*.

MELIC GRASS.—*MELICA*.

MELICA (MELIC GRASS. Nat. Ord. Gramineæ).—This is a genus of hardy grasses, all of which are perennials of no great garden value, but may be grown in the wild garden. *M. altissima atropurpurea* is quite the best species to grow, though *M. ciliata* (Syns. *M. cretica* and *M. glauca*) comes near it. These grasses average 3–4 ft. in height. *M. uniflora* is a very dwarf sort, the height of which only averages 6–9 ins.

MELILOT.—See *MEDICINAL HERBS* and *MELILOTUS*.

MELILOTUS (MELILOT. Nat. Ord. Leguminosæ).—This is a genus of hardy annuals, hardy biennials, hardy perennials, and hardy shrubs, none of which merit cultivation. *M. officinalis*, the MELILOT of waste land, is briefly referred to under this latter name in our article on *MEDICINAL HERBS*.

MELISSA (Nat. Ord. Labiatæ).

Only one species of this genus is grown in gardens. This, *M. officinalis*, is included in our article on *POTHERBS*, under BALM, where its culture is briefly described. Two other species, *M. alpina* and *M. grandiflora*, formerly classed in this genus, have now been transferred to

the genus *Calamintha* (see article on CALAMINT), where they will be found described under *C. alpina* in the rock garden species, and *C. grandiflora* in the perennial border species.

MELITTIS (BASTARD BALM. Nat. Ord. Labiatæ).—One species of this genus, *M. Melissophyllum*, known by some people as HONEY BALM, apart from its medicinal value, is of sufficient merit to be grown in the herbaceous border, as it is a hardy perennial. It bears flesh-pink flowers in May and June, on plants 1 ft. high, and may be treated in the usual manner for hardy perennials. (See also BALM in article on *POTHERBS*.)

MELOLONTHA and MELOLONTHIDÆ. — See CHAFERS in *INSECT PESTS*.

MELON (*Cucumis Melo*. Nat. Ord. Cucurbitaceæ).—Where early melons are needed, small, sufficiently heated lean-to or span-roofed pits are the best. For summer crops span-roofed houses and frames may be utilised. Bottom heat must be furnished by hot-water pipes or by leaves and stable litter, and should be maintained as near 75° F. as possible. The minimum temperature should be 60° F. to 70° F., and the maximum 80° F. to 90° F. Up to a certain point the melon is one of the easiest fruits to grow; the critical time comes when the fruits are approaching ripeness.

Compost.—This should be a rather strong loam with a little old lime rubble and burnt earth added. The beds need not be more than $2\frac{1}{2} \times 2$ ft., or the compost more than 18 ins. in width to commenee with. Form this into a ridge the whole length of the bed. The plants may be set out about 18 ins. apart, and two, three, or four fruits allowed to each plant. Attention must be given to tying in the shoots and stopping of laterals If very early fruits are required, do not stop the plants until after the fruits are set. Secure two or three fruits, and fertilise at the same time if possible. The earlier the date operations are commenced, the more artificial heat and attention are required. Sow the seeds singly in small pots and plunge in a bottom heat of 75° F. Allow about four months from sowing to ripening in early spring, and three months in the summer. They may be grown on the extension system of two or three shoots, or on single stems, which some consider the better and more profitable mode of culture. Grown on single stems in 11-inch pots is far the best method for early work; then canker, one of the greatest troubles, is almost unknown. Fertilise the flowers, and support the fruits when they attain the size of a cricket ball by nets, and stop laterals to avoid overcrowding.

Watering and Ventilation. — As light and growth increase, the plants must be liberally supplied with slightly warmed water. During the time the fruits are swelling assist the plants with weak stimulants. Little or no water will be required when the fruits are ripening, but ventilation must be increased considerably. Melons do not require much air during the growing period; top ventilation is ample, with liberal supplies of moisture in the atmosphere.

Frame Melons.—A hotbed should be made up in May, placing one mound of soil for each light, and setting two or three plants on each mound. Pinch out the points when the plants have made about 18 ins. of growth to induce the formation of other shoots. Fertilise the female flowers until three or four fruits are obtained on each plant. Keep the growths thinly trained by frequent

pinching or by the removal of a few superfluous shoots, supplying the necessary moisture as recommended.

Varieties.—These are numerous; the following may be relied upon:—

Green Fleshed Sorts.—Dickson's Exquisite, Emerald Gem, and Ringleader.

Scarlet Fleshed. — Blenheim Orange, King George, and Superlative.

White Fleshed.—Eminence, Hero of Lockinge, and The Countess.

F. J.

MELON FRAMES. — See *GREENHOUSES AND FRAMES.*

MENISPERMUM.—For best species see *CLIMBING AND TRAILING PLANTS.*

MENTHA (MINT. Nat. Ord. Labiatæ).—This is a genus of hardy herbaceous and spreading perennials of the easiest culture. *M. arvensis* is the well-known CORN MINT; *M. piperita* is the PEPPERMINT used in medicine and confectionery; *M. Pulegium* is the equally well-known PENNYROYAL. (See article on *POTHERBS* for hints on culture of these two.) *M. rotundifolia* is known as APPLE MINT, and is comparatively unimportant. *M. sylvestris*, known as HORSE MINT, must be carefully distinguished from the more useful AMERICAN HORSE MINT (*Monarda punctata*), described in our article on *POTHERBS*. The most useful species of all is *M. viridis*, the GARDEN MINT or SPEAR MINT, referred to in our article on *POTHERBS* under the former name.

MENTZELIA (Syn. *Bartonia*. Nat Ord. Loasaceæ).—The beautiful little Californian annual so frequently labelled *Bartonia aurea* or *B. crocea*, is really *Mentzelia Lindleyi*. It loves the sunshine, and produces its wide, five-petalled golden blooms over a considerable period in the summer and autumn. As the individual flowers are 1½ ins. across, a group of plants in bloom gives a fine effect. It is best treated as a half-hardy annual, but does well in the southern counties if sown in a warm position in March or April. It grows 1½ ins. high.

MENYANTHES (BOG BEAN or BUCK BEAN. Nat. Ord. Gentianaceæ). — The one species of this genus, *M. trifoliata*, is a bog plant pure and simple. It is referred to in our article on *MEDICINAL HERBS*, under BUCK BEAN, and must not be confused with BUCKWHEAT, to which a reference is made in our notes on *FAGOPYRUM*.

MENZIES SPRUCE (*Picea sitchensis*). See *TREES*.

MENZIESIA.—For the best species see *SHRUBS*.

MENZIESIA POLIFOLIA.—See *Daboëcia polifolia* in *HEATHS*.

MERCURIALIS (DOG'S MERCURY. Nat. Ord. Euphorbiaceæ).—This is a genus of highly poisonous annual and perennial plants found wild in hedge bottoms and other places. It must not be mistaken for the plant known as *MERCURY*, or *GOOD KING HENRY* (*Chenopodium Bonus-Henricus*), used for food, and upon which we devote a separate article. The two species usually found are *M. annua*, known also as BARON'S MERCURY, and *M. perennis*, also known as KENTISH BALSAM. Detailed descriptions of these may be obtained by consulting works on wild plants.

MERCURIC CHLORIDE.— See *MERCURY COMPOUNDS.*

MERCURY, BARON'S AND DOG'S.— See *MERCURIALIS.*

MERCURY COMPOUNDS.

Very few compounds of mercury are of any value to the gardener, and are somewhat costly to experiment with. Mercuric and Mercurous Nitrate may have some future

horticultural use, but at present, so far as we know, their effects on plant life in general have not been determined. The metal Mercury itself is largely used in thermometers under the name of QUICKSILVER, and if some is obtained from a broken thermometer it will be found to dissolve other metals to an appreciable extent. These solutions are known to chemists as AMALGAMS. Zinc is often immersed in a bath of the metal to be "amalgamated," and the majority of the sheets the gardener uses in his electric batteries, etc., are of metal so treated. If tin be dissolved in the metal, the product may be spread on the back of thick glass and this suitably framed, when a home-made mirror will result.

The only compound of mercury of much horticultural interest is *Mercuric Chloride*, popularly known as CORROSIVE SUBLIMATE. This may be used as a fungicide, putting about 1 oz. into 8–10 gals. of water; or as a worm eradicator as described in our article on *WORMS*. It is a deadly poison, so should always be kept under lock and key.

MERCURY, or Good King Henry (*Chenopodium Bonus-Henricus*, not of the genus *Mercurialis*. Nat. Ord. Chenopodiaceæ).—Although extensively grown in some parts of England (notably in Lincolnshire and on the eastern coast), this is but little known in others. It is generally regarded as an excellent substitute for Asparagus, giving splendid results, with but little trouble, in those districts where the more popular Asparagus can only be grown after considerable expense in the matter of soil preparation. In some quarters the plant is grown exclusively for the young leaves, which, when properly cooked, form a truly delicious vegetable, preferred by many to Spinach. It is quite an easy matter to raise a stock from seed, or young plants may be purchased from those who make a speciality of the crop.

Culture.—The seed should be sown in nice friable soil, as early in the spring as the state of soil allows, always avoiding land in a constantly water-logged condition. If more than one row is to be sown, allow at least a foot between the rows, and after the seedlings are well through the soil, thin out to about 9 ins. apart, at which distance each plant will make sturdy growth, and build up strong crowns from which good supplies of shoots or leaves should be taken the following year.

Although not usual, where the plants enjoy a deep, rich root run it is quite permissible to gather a few of the large outer leaves the first summer; but this should not be indulged in to such an extent as to weaken the plants.

Throughout the whole season of growth keep the bed free from weeds, and the roots moist by repeated applications of manure water. Always give the beds a top-dressing of rich manure previous to the plants making new growth in the spring.

F. R. C.

See also *CHENOPODIUM*.

MERODON. — See NARCISSUS BULB FLY in *INSECT PESTS*.

MERTENSIA (SMOOTH LUNGWORT. Nat. Ord. Boraginaceæ).—This is a genus of useful perennial border and rock garden plants, which are not as widely grown as they should be. Most of them flower freely, and will, when once grown, become favourite flowers. They succeed in ordinary light, rich, sandy soil which is not too moist, and are easily increased by seeds sown in the early summer, by cuttings of the young growths under a hand-light in August, or by

division of the roots in the autumn or March, at which latter period they may be most successfully planted. We recommend the following for the perennial border :—

Mertensia alpina. — This is a species for edging, and bears blue flowers in May, only growing 6 ins. high.

M. maritima (Oyster Plant). —This also is useful for edging purposes or marginal patches to borders, though slugs are very destructive amongst it. Its blue flowers are borne in June and July, on plants 3–4 ins. high.

M. paniculata.—This is a pretty blue sort blooming from April to June, and growing 1½ ft. high.

M. pulmonarioides (Syn. *M. virginica*).—This is an attractive blue May flowering sort growing 1–2 ft. high.

M. sibirica.—This is a blue June flowering sort growing 3 ft. high.

M. virginica.—Syn. *M. pulmonarioides* above.

Rock Garden Species.—Only two species are really useful in the rock garden, and both are tufted, spreading perennials, readily increased by division of the roots in the spring. We briefly describe them below :—

Mertensia echioides.—This is a dwarf-growing plant bearing tufts of entire leaves. Flowers, deep blue with a yellow eye, in racemes. Site, half-shade. Soil rich, well-drained, and stony. Flowering Period, June. Height, 9 ins.

M. primuloides.—This is a spreading plant. Flowers, purplish-blue. Site, half-shade. Soil rich and gritty. Flowering Period, June. Height, 6 ins.

MESEMBRYANTHEMUM (Fig Marigold. Nat. Ord. Ficoideæ).—This is a free-flowering, greenhouse succulent plant of easy culture, and is suitable as a window plant or for rockwork out of doors in summer. It is propagated by cuttings of half-ripened shoots in spring in sandy soil, and should be potted in good fibry loam, peat, and sand which is well-drained. Temperature required, 40–50° F.

Greenhouse Species.— *Mesembryanthemum bicolorum.* — Orange. Flowers in July. Height, 1–1½ ft.

M. capitatum. — Pale yellow. Flowers in August. Height, 1–1½ ft.

M. coccineum.—Scarlet. Flowers in July. Height, 1–1½ ft.

M. crystallinum (Ice Plant).—An annual, with leaves and stem thickly covered with sparkling, ice-like globules. Flowers, pinkish shade, in August. Height, 5 ins.

M. fastigiatum.—White. Flowers in August. Height, 1–1½ ft.

M. formosum.—Crimson. Flowers in August. Height, 1–1½ ft.

M. incurvum.—Pink. Flowers in July. Height, 1–1½ ft.

See also *Annuals, Half-Hardy : List of.*

METALLIC ELEMENTS.—See *Chemistry for Gardeners.*

METAMORPHIC ROCKS.—See under Kinds of Rocks in *Garden Geology.*

METROSIDEROS (Nat. Ord. Myrtaceæ).—This is undoubtedly the best of all Myrtaceous plants. It can be grown as a bush, pyramid, or standard. It is allied to *Leptospermum* (which see), and requires the same culture.

Greenhouse Species.—*Metrosideros floribunda* (Bottle Brush). — Bright red. Flowers in April and May. Height, 2–6 ft.

MEUM (Baldmoney and Spignel. Nat. Ord. Umbelliferæ). — The offering of this worthless genus is becoming quite a common practice, so we include it here for the purpose of warning readers not to purchase

it. *M. athamanticum* is the best known species, and is found growing wild. It bears whitish flowers in June, and averages 1½ ft. in height.

MEXICAN ORANGE FLOWER.—The genus CHOISYA and *Choisya ternata*. See *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

MEZEREON (*Daphne Mezereum*).—See *SHRUBS*.

MICE.—See *GARDEN ENEMIES*.

MICHAELMAS DAISIES.—See *ASTER*.

MICHAUXIA (Nat. Ord. Campanulaceæ). — This is a small genus of striking hardy biennial border plants suitable for sunny sites. They may be raised by sowing seeds in warm, sunny borders out of doors in April, and subsequent thinning out to 2 ft. or so asunder, as they dislike being transplanted. Light protection in the winter is advisable in cold districts. The following are the best :—

Michauxia campanuloides.—This bears light red or rose flowers in July, on plants 4–5 ft. high.

M. laevigata.—This is a noble and striking plant producing white flowers in August, and growing 9–11 ft. high.

M. Tchihatcheffi.—This also bears white flowers, but blooms a month earlier than the last named species and averages 4–6 ft. high.—J. F.

MICRANTHES.—Now included in the genus *SAXIFRAGA*.

MICROLEPIA.—Now included in the genus DAVALLIA, for which see *FERNS AND FERN GARDENING*.

MICROSORIUM.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING*.

MIGNONETTE (*Reseda*. Nat. Ord. Resedaceæ). — These fragrant plants are among the most popular of annuals, and deservedly so, as they are so easily grown. Their sweetness adds to the amenities of any garden. Where any difficulty is found in growing Mignonette, add some lime to the soil. Sow at intervals in spring and early summer, making the seed-bed firm, and thin out well ; if transplanting is done it must be when the seedlings are very small, as they are tap-rooted.

The best sorts are :—

Reseda alba.—A white summer blooming sort 2 ft. high.

R. lutea.—A yellow sort, blooming from June onwards, and averaging 1 ft. high.

R. odorata.—This is the fragrant Italian species from which the garden forms have been evolved. The varieties vary in colour, height, and robustness, many of them having been given distinctive names. There are cream-white, buff-yellow, golden, orange-buff, and red forms, ranging from 6–18 ins. in height. The *Matchet* variety is very sturdy, and makes a capital pot plant for winter flowering under glass.

MILDEW, APPLE.—See *APPLE DISEASES*.

MILDEWS.

In a botanical sense the term "mildew" is confined to special diseases of plants caused by a certain definite group of fungi, the *Erysiphaceae*. This group—the "true Mildews," or *Powdery Mildews* — is characterised by being quite superficial in its growth. That is, unlike the rust and most parasitic fungi, the mycelium (or system of fungus filaments) is external, and only inserts minute suckers into the host-plant to extract its food. In spite of this, mildews cause serious damage (*e.g.* mildews of apple, gooseberry, oak, rose, etc.). As a rule each host has its own particular mildew. From their superficial habit of growth, the mildew fungi are easily seen, and specially suitable to be controlled by the use of spraying mixtures or powders. The great secret is to apply early.

Some of the lower fungi are sometimes called *False Mildews* (*e.g.* Onion Mildew). Here, though the appearance suggests a true mildew, the mycelium is found to be internal. The False Mildews are in reality related to the Potato Blight fungus.

A. D. C.

MILFOIL.—See *ACHILLEA*, and under YARROW in *MEDICINAL HERBS*.

MILIUM (MILLET GRASS. Nat. Ord. Gramineæ). — *M. effusum* is the best species of this little genus of annual and perennial grasses. Unless the collection is a very large one, the genus may be dispensed with. Otherwise a place may be found for it in good light soil in the wild garden. This genus must not be confused with *SORGHUM*, which see.

MILK THISTLE (*Carduus benedictus*). A name applied to the HOLY THISTLE, which see in *MEDICINAL HERBS*.

MILK THISTLE (*Silybum marianum*). See *SILYBUM*.

MILK VETCH.—See *ASTRAGALUS*, and under ASTRAGALUS in *SHRUBS*.

MILK-WORT.—See *POLYGALA*.

MILKWEED.—See *ASCLEPIAS*.

MILLA.—Now included in the genus *BRODIAEA*.

MILLEPEDES.—See *INSECT PESTS*.

MILLET (*Panicum miliaceum*).—See *PANICUM*.

MILLET GRASS.—See *MILIUM* and *SORGHUM*.

MILLET, ITALIAN (*Setaria italica*).—See *SETARIA*.

MILLET RICE (*Panicum colonum*).—See *PANICUM*.

MILLSTONE GRIT.—See under SANDSTONE in *ROCKWORK*.

MILTONIA and MILTONIODA.—See *ORCHIDS*.

MIMOSA.—See *ACACIA*.

MIMULUS (MONKEY FLOWER. Nat. Ord. Scrophulariaceæ).—This is a genus of hardy and half-hardy annuals, hardy perennials, and rock plants. The two former classes are comparatively unimportant, but may be raised by sowing in heat in February and planting out later, after duly hardening them off. They are useful for summer bedding and for greenhouse decoration. There are numerous named hybrids to choose from in seedsmen's lists, and improved varieties are being introduced so frequently that no good purpose could be served by describing any here.

Perennial Border Species.—These are attractive, hardy plants, some of fine, tall growth, but mostly dwarf growing, and thus suitable for the margins of borders and so on. They succeed in good garden soil, but require plenty of water in the summer, and thus a damp, lightly shaded spot is desirable, or a moist bank near the water. In cold, exposed districts it is well to lift them and winter in a frame. They may be raised from seeds sown on a very fine, moderately firm, and very sandy seed-bed, in a frame in the spring or summer, and may also be propagated by cuttings in the summer, or by division of the roots in the autumn or early spring. March is the best time to plant. The following include the best sorts, the first two of which, as well as *M. luteus* and *M. radicans*, are splendid water garden plants. (See under MONKEY FLOWER in article on *WATER GARDEN: PLANTS FOR THE*).

Mimulus cardinalis. — A bright scarlet June flowering sort about 2 ft. high.

M. cupreus.—This is an exceedingly attractive orange sort flowering from June to August, and growing about 1 ft. in height.

M. glutinosus.—This is a useful sort for margins, and bears light purple flowers in July and August. It grows about 12 ins. high.

M. luteus.—This dwarf sort, useful for edgings, etc., bears yellow flowers in July and August, and grows 6–12 ins. high. Its varieties *alpinus* and *guttatus* bear copper-yellow and pale yellow flowers, and grow 6 ins. and 18 ins. in height respectively.

M. moschatus (Musk). — This well-known creeping perennial is useful for margins, edgings, etc., out of doors, and is largely grown as a pot plant in the greenhouse. Its yellow flowers are abundant in July and August, on plants 6 ins. high.

M. radicans.—This, described in the next section, may also be grown with success in moist borders and in the water garden.

M. ringens. — This pretty sort bears pale blue flowers in July, and grows 12 ins. high.

Rock Garden Species. — The following two species are well worth a place in the rock garden, and are propagated by division of the roots in the autumn or spring, or by seeds sown in finely prepared beds out of doors in March.

Mimulus primuloides.—This is a dwarf creeping plant with tufts of hairy foliage. Flowers yellow on slender stalks. Site, half-shade. Soil moist, peaty, and gritty. Flowering Period, June to September. Height, 4 ins.

M. radicans.—This forms carpets of bronzy-green leaves. Flowers white, with a violet blotch. Site, half-shade. Soil moist, peaty, and gritty. Flowering Period, July to August. Height, 2 ins.

New Variety.

Mimulus Wargrave Fireflame.—This is a variety of *M. luteus alpinus* bearing scarlet-crimson flowers on plants 6 ins. high.

MINA.—Now included in the genus *Ipomoea*. Its well-known garden variety (Lobata) is described under *Annuals, Half-Hardy : List of*.

MINORCA BOX (*Buxus balearica*).—See *Shrubs*.

MINT.—See under Peppermint in *Potherbs*, and also *Mentha*.

MINT RUST. — See *Diseases of Plants*.

MIRABILIS.—See *Marvel of Peru*.

MISANDRA.—Now included in the genus *Gunnera*.

MISCOPETALON.—Now included in the genus *Saxifraga*.

MISSOURI CURRANT (*Ribes aureum*). See *Shrubs*.

MISTAKES IN PLANTING.—See *Bedding Out : Practical Hints on*.

MISTLETOE.

This is in great demand at Christmas time and up to the New Year, although the custom of kissing under the mistletoe is dying out, except perhaps amongst sentimental young ladies and gentlemen. If it is desired to grow mistletoe, some ripe berries must be obtained, and one or two of them inserted in small cuts made in the bark of apple trees. The wound can then be bound over and the seed left to grow into the tree. Very little cutting will be possible until after the end of the third or fourth year.

MISTLETOE CACTUS (*Rhipsalis salinorcoides*).—See *Cacti*.

MITELLA (Mitre Wort. Nat. Ord. Saxifragaceæ).—This is a small genus of dwarf-growing plants which may be used in the rock garden or front portions (edgings, etc.) to mixed and other borders. All are hardy herbaceous perennials, which thrive under the treatment usually given such subjects, and may be propagated by root division in March, at which times they may be most suitably planted. *M. Breweri*, *M. diphylla*, and *M. nuda* are the best white sorts, blooming from April to July, and growing 3–6 ins. high. *M. pentandra* is a useful yellow sort blooming in June, and growing 6 ins. high.

MITRARIA.—For the best species see *CLIMBING AND TRAILING PLANTS.*

MITRE FLOWER (*Mitraria coccinea*). See *CLIMBING AND TRAILING PLANTS.*

MITRE WORT.—See *MITELLA.*

MIXED BORDER, THE.

In a recently published book (1917) there is an attack on what is popularly known as "The Mixed Border." The writer of the book makes some interesting statements worthy of consideration, but nevertheless we propose to praise Mixed Borders as much as we can in this Dictionary.

A Mixed Border is without limit in its possibilities. It need not be limited to hardy plants, nor to one class of hardy plant, as for instance the hardy herbaceous perennial. It may be composed of or planted with almost any and every plant under the sun (except, of course, stove-house subjects and tender climbers). Thus there are no bounds to the possibilities of colour, grace, and form which may be shown off in the border.

One border we saw last summer convinced us that "mixed" gardening was capable of producing superbly lovely effects both in colour and form. It contained in addition to the usual hardy and half-hardy annuals and perennials, numerous beautiful greenhouse annuals and greenhouse perennials. It was (in August), a sheet of colour from one end to the other, this being managed by having plants brought on in greenhouses and frames ready to plant out the moment the other plants were over.

If Mixed Borders are to be the enormous success they can be, then one has always to be on the watch. Plants may fail on account of the weather, and must be replaced immediately. Again deaths may occur owing to soil pests, or owing to lack of attention in watering. All these must immediately be made good. A large additional stock of plants is in any case required, which is apt to make this form of gardening somewhat expensive. But undoubtedly it is well worth doing.

Successful and beautiful Mixed Borders can only be obtained by careful and thorough study of the plants beforehand. Clashing colours *must* be avoided, height and habit as well as period of blooming must be allowed for, or what might be a beautiful Mixed Border will be an infamous fiasco. Alternative plants for filling in gaps caused by failures must be grown to be ready at once.

Careful attention to practical details such as staking, etc., must also be given, as described in the articles on *HERBACEOUS BORDERS.*

Plants Suitable.—Below are given the various sections of plants suitable for the present purpose, with the names of the articles in which lists may be found:—

HARDY AND HALF-HARDY ANNUALS.—The vast majority of the hardy annuals given in the list included in our article on *ANNUALS FOR ALL PURPOSES* are very suitable, while among half-hardy sorts all those given in our notes on *ANNUALS, HALF-HARDY: LIST OF,* may be used.

HARDY AND HALF-HARDY BIENNIALS.—Any of those in the list of Hardy and Half-Hardy Biennials included in our article on *BIENNIALS* may be used.

PERENNIALS. — All those mentioned in the article on *PERENNIALS FOR ALL PURPOSES* may be used, in the case of the hardy sorts, while all the half-hardy plants given in our notes on *PERENNIALS, HALF-HARDY: LIST OF,* are more or less suitable.

GREENHOUSE PLANTS:—*Annuals.*—A short list of Greenhouse Annuals

appears at the end of the article on *Annuals for All Purposes.*

Perennials, etc. — An enormous number of greenhouse plants are available for this work provided that they are thoroughly hardened off before planting out. The best greenhouse plants are briefly described in alphabetical order throughout the work.—E.

MIXED PRODUCTS. — See under General Manures in *Manures.*

MIXING MORTAR.—See *Mortar.*

MIXING TOP-DRESSINGS. — See *Top-dressing.*

MOCK ORANGE.—The genus Philadelphus. See *Climbing and Trailing Plants* and *Shrubs.*

MOCK ORANGE (*Prunus caroliniana*). See *Trees.*

MOCKER NUT (*Carya tomentosa*).— See *Trees.*

MOEHRINGIA.—Now included in the genus *Arenaria.*

MOISTURE FOR SEED.—See *Germination of Seeds.*

MOLE CRICKET.—See *Insect Pests.*

MOLES.—See *Garden Enemies.*

MOLINIA (Nat. Ord. Gramineæ). This is a small genus of weedy perennial grasses quite unworthy of cultivation. *M. caerulea* (Syn. *M. varia*) is popularly known as Lavender Grass. It and its variety *variegata* may be seen at Kew.

MOLTKIA (Nat. Ord. Boraginaceæ).—Only one species of this genus (*M. petraea*) is grown at Kew. This is a blue-flowered hardy herbaceous perennial suitable for the borders though best in the rock garden, bearing its flowers from June to August, and growing about 6 ins. in height. It will succeed in light, rich garden soil, but otherwise requires the usual treatment for hardy perennials. The best way to propagate it is by division of the rootstock in March, at which time it may be successfully planted.

MONARDA (Bergamot, Horsemint, etc. Nat. Ord. Labiatæ).—This is a useful genus of hardy perennial border plants and herbs. American Horsemint is described in our article *Potherbs,* and Wild Bergamot with its delightful scent is almost too well known to need description. The cultural requirements of the genus are of the simplest; all thrive in good, rich garden soil, though this must be well on the moist side. They are best propagated by division of the roots in March, which is also a suitable time to plant. We recommend the following for herbaceous borders:—

Monarda citriodora. — This has lemon-scented foliage, and bears yellow flowers in August on plants 2 ft. high.

M. didyma (Syn. *M. fistulosa* of Curtis).—This, the Oswego Tea, is a favourite species with scented foliage and scarlet flowers, which last are produced in July and August on plants 3–5 ft. high. Various varieties of it are offered by nurserymen, of which *alba* is white; *Cambridge Scarlet* is, as its name implies, bright scarlet; while *kalmiana* (offered at times as a species) is bright red.

M. fistulosa (Wild Bergamot).— The variety *mollis* (Syn. *M. menthaefolia*) is far superior to the wild plant, and bears attractive lilac flowers from July to August, on plants 2 ft. high.

MONK'S RHUBARB (*Rumex alpinus*). See *Rumex.*

MONKEY FLOWER (*Mimulus*).—See *Mimulus* and *Water Garden: Plants for the.*

MONKEY PEAS.—See under Woodlice in *Insect Pests.*

MONKEY PUZZLE.—A name applied to the genus Araucaria, more especially to *A. imbricata.* See *Trees.*

MONKSHOOD.—See *Aconitum,* and see under Aconite in *Medicinal Herbs.*

MONTBRETIA (*Tritonia*. Nat. Ord. Iridaceæ).—The Montbretias come from South Africa. They bear yellow, orange, or orange-red flowers on long branched, wiry stems about 3–4 ft. high. They have sword-like leaves and rhizomatous roots, which every now and again swell into corms. Most of the newer hybrids, *e.g.* the *Earlham Hall* varieties, are not perfectly hardy, and need to be lifted annually; but some of the older varieties may be treated as hardy plants. Their flowering season is late summer and early autumn.

Culture.—Montbretias like light, rich, well-drained soil and a sunny position. All the varieties should be planted in early April, and the more tender ones lifted in October, the corms being stored in sand all winter in a frost-proof place until the time for planting comes round again. When in active growth they need occasional watering with some weak stimulant to bring them to the highest perfection.

Montbretias may be grown indoors by potting up the corms in the early part of the year, plunging the pots up to the rim in ashes in a frost-proof frame and bringing them into a greenhouse in early June. For getting seed, indoor culture is essential, but red spider must be guarded against.

Varieties[1]**:** *Tritonia citronella.*—A pale yellow and highly decorative sort. Height, 3½ ft.

T. Croesus.—An orange or yellow sort about 3½ ft. high.

T. Etoile de Feu.—A glowing orange-red sort. Height, 2½ ft.

T. George Davison.—This also is orange, and grows about 3 ft. high.

T. George Henley.—A chrome-yellow sort with flowers tinged with red. Height, 3½ ft.

T. Germania.—An attractive orange-scarlet sort growing 4 ft. high.

T. King Edmund.—A golden-yellow sort with carmine centre. Height, 3½ ft.

T. Lady Hamilton.—The flowers of this are apricot-yellow, and charming shape. Height, 3½ ft.

T. Prometheus.—A sort with fiery orange flowers, growing 4 ft. high.

T. Queen Adelaide.—A sort with immense deep orange flowers shading to red. Height, 4 ft.

T. Queen Alexandra.—A sort with pale apricot-yellow flowers, and dark eyes. Height, 4 ft.

T. Queen Mary.—A light orange-yellow sort. Many flowers on this variety open out at once. Height, 3½ ft.

T. rosea.—This is a lovely shade of pink, with slender stems and quite unlike the others in its general appearance. Height, 2 ft.

T. Star of the East.—This has orange-yellow flowers with a lemon eye, and grows 3½ ft. high.

All the above varieties flower in either August or September.

J. J. & E. T. E.

New Varieties.

Tritonia His Majesty.—This bears yellow flowers, shading to crimson-scarlet.

T. Nimbus.—This bears orange-yellow flowers which are darker on the back. They are often 3–4 ins. across.

T. Queen Elizabeth.—This bears large, deep orange-scarlet flowers, shaded crimson.

T. Queen of Spain.—This bears large orange-yellow flowers blotched crimson and shaded on the back with the same colour.

T. Una.—This bears bright yellow flowers, shading to crimson at the tips.—W. J. C.

[1] Only two Tritonia species figure in the *Kew Hand-list*. These, *T. crocosmaeflora* and *T. Pottsii*, are relatively unimportant.—Editor.

MONTEREY CYPRESS (*Cupressus macrocarpa*).—See *TREES*.

MONTEREY PINE (*Pinus insignis*).—See *TREES*.

MONTHLY ROSE (*Rosa indica*).—See *ROSE SPECIES*.

MOOSE WOOD (*Acer pennsylvanicum*). See *TREES*.

MOP-HEADED CATALPA (*Catalpa Bungei*).—See *TREES*.

MORAEA (Nat. Ord. Iridaceæ). None of the numerous species of this genus are common in British gardens. The one mentioned here, the best known of the family, is only hardy in very favoured positions, but when pot-grown makes a pleasing and uncommon decoration in the conservatory.

Culture.—The bulbs should be planted, five or six in a 5-inch pot in autumn and wintered in a cold frost-proof frame. They may be removed into a cool greenhouse in February or March. It is best to lift bulbs planted in the open ground every year.

Species: — *Moraea glaucopis.* — This bears in June small iris-like flowers which are pure white with a real blue spot on each of the outer segments. Height, 1 ft.—J. J.

[The two species figuring in the *Kew Hand-list of Herbaceous Plants* are *M. iridioides*, and *M. spathacea*. The first bears white flowers in July, and the second clear yellow flowers in the early spring. The height averages 6–12 ins.—EDITOR.]

MORAINE GARDENING.

It is completely deplorable that this form of gardening is still in its infancy, for it is the best and surest means of growing practically all the most difficult of the Alpine gems, and this being so, we hope the few hints below may be useful.

First of all, let us be quite clear as to what a Moraine is. Briefly, it is the accumulation of stones and other débris found at the foot, along the edges, or down the centres of glaciers, and at the foot of precipitous cliffs. Such a compost is very porous, affording absolute drainage for the plants, and tending to keep them warm and dry during the winter months, when, in their native habitats, they are covered with frozen snow. As the summer advances, the plants on these natural Moraines are watered continuously by the melting snow, which keeps the compost cool and moist, without stagnation, owing to its porosity. This is the growing season for the many gems which are found on these natural Moraines, and thus we find, if we would imitate Nature, we must, in making an artificial Moraine, first, have a porous compost of sufficient depth, with ample drainage beneath; secondly, provide ample water for the needs of the plants during their growing season; and thirdly, arrange that the plants may be kept as dry as possible during the autumn and winter months, when growth has ceased and they are quite dormant. These conditions are the *sine qua non* for all who desire to make a Moraine, and who wish to grow plants well and successfully on it. As the climatic conditions in the British Isles are somewhat erratic,

and we often get a superabundance of rain when we least require it, Moraine gardening is sure to be a successful way of growing the choicest Alpine gems which would fail under ordinary rock garden conditions.

Making a Moraine.—When making a Moraine it should, when possible, be at the foot of a precipitous cliff, where the ground slopes gently to the south or south-west. Excavate the portion intended for a Moraine to the depth of about 3 ft., filling in with rough cobble stones to half that depth, and then cover the same with leaves or thin turves in order to keep the drainage clean. The compost, which should consist of, say, 4 parts of chips to 1 part of sifted loam, peat, leaf-mould, and sharp sand well mixed, should then be added to fill up to the required level. If limestone, granite, or sandstone chippings (preferably screened through a ½-inch riddle) cannot be obtained locally, clean gravel or well-washed sharp river sand may be used in the proportions already given. Flat stepping-stones can be sunk level with the surface of the Moraine, and these can be placed irregularly 12–15 ins. apart, so that one may be able to get easily amongst the plants without any danger of stepping on them. A few boulders may also be introduced, and arranged naturally, to break the monotony, and to provide partial shade for such plants as do not require full sun.

Watering.—Regarding this, in the summer months subterranean watering is preferable. This can be arranged by means of ½-inch pipes connected to the main with a stop-tap, and perforated on each side with minute holes four inches or so apart. These should be placed 4–6 ins. below the surface, and when autumn comes the stop-tap should be closed to allow the water to drain from the pipes. Another system is to procure a bamboo curtain-pole, and cut it into sections below each joint. These will provide a number of tubes with one end sealed. Perforate these with minute holes and insert into the Moraine 12–18 ins. apart. Fill these tubes with water as often as necessary, and allow this to percolate gradually through the compost, repeating the process whenever the weather is hot and dry.

What to Grow.—We give below a list of plants suitable for growing on a Moraine, which, though far from complete, may serve as a guide to those who intend to take up this interesting branch of Alpine culture. Those plants with a single star in front of their name require a non-calcareous soil, and those with two stars need moist shady situations. It should be noted that *Ranunculus glacialis* requires both these conditions :—

	Inches
**Androsace alpina* (Syn. *A. glacialis*). Rose white. May and June.	1
**A. argentea* (Syn. *A. imbricata*). White. May and June.	1
A. villosa. Pearly white. May and June.	3
Artemisia splendens. Silvery foliage. May to July.	4–6
Asperula Athoa. Pink. May to July.	3
Aster alpinus. Purple. May to July.	6–8
Campanula acuteangulare. Deep purple. July and August.	4
**C. alpestris* (Syn. *C. Allionii*). Purple. June and July.	3
**C. cenisia*. Electric blue. June and July.	2
**C. excisa*. Violet. July and August.	4
C. pulla. Deep violet. July and August.	6
C. Raineri. Blue. July and August.	3
C. Zoysii. Blue. July and August.	4
***Cyananthus lobatus*. Blue. July and August.	4

	Inches
Dianthus alpinus. Rich rose. June and July.	4
D. arvernensis. Pink. June and July.	4
D. callizonus. Deep rose. June and July.	4
D. Freynii. Blush. June and July.	2
**D. glacialis.* Rose. June and July.	4
**D. neglectus.* Fiery rose. June and July.	4–6
D. nitidus. Rose. June and July.	6
D. sylvestris. Rose. June and July.	8
**Eritrichium nanum.* Dazzling blue. June.	2
Iberis saxatilis (Syn. *I. petraea*). White. June.	3
Leontopodium alpinum. Silver-white foliage. May to August.	6
Linaria alpina. Violet and gold. May to August.	3
Lithospermum Gastoni. Blue. June and July.	6
***Mertensia primuloides.* Blue to amethyst. June and July.	6
Morisia hypogaea. Yellow. April to June.	3
Myosotis rupicola. Blue. June.	3
Papaver alpinum. White, yellow, rose. May to August.	6
Petrocallis pyrenaica. Pinky-white. June.	2
***Primula intermedia.* Rosy-lilac. May and June.	4
***P. spectabilis.* Rosy-lilac. April to June.	4
***Ranunculus alpestris.* White. May to August.	4
***R. bilobus.* White. May to August.	4
***R. glacialis.* White and shades of red. May and June.	6
***R. parnassifolius.* White. May and June.	6
***R. Seguieri.* White. May and June.	6
**Saponaria lutea.* Yellow. June.	3
Saxifraga Aizoon. Rosy-pink and white. May and June.	6
S. Burnati. White. June.	6
S. burseriana in its many forms. White. February and March.	3
S. caesia. White. June.	4
S. Faldonside. Yellow. March.	4
S. Grisebachii. Red. March and April.	6
**Silene Elizabethae.* Rose-red. June.	4
S. Hookeri. Rose-pink. June.	6
**S. Pumilio.* Pink. June.	3
**Soldanella pyrolaefolia.* Lilac. March to April.	4
Thlaspi limosellaefolium. Lilac. May to June.	4
T. rotundifolium. Lilac. May and June.	4
Veronica canescens. Blue. May to July.	2
Viola cenisia. Violet. May to July.	4
Wahlenbergia (Syn. Edraianthus) *Pumilio.* Violet. May to June.	4
W. serpyllifolia major. Deep violet. May to July.	4

The culture of many of these plants is more fully described under their respective genera.—G. R.

MORAINES: PLANTS FOR. — See *MORAINE GARDENING.*

MOREL. — See EDIBLE FUNGI in *FUNGI: EDIBLE AND HARMFUL.*

MORELLO CHERRIES.—See *CHERRIES.*

MORELLO CHERRY (*Prunus Cerasus*). See *TREES.*

MORINA (Nat. Ord. Dipsaceæ). This is a genus of herbaceous perennials which are not very hardy, and thus require wintering in a frame or greenhouse, otherwise the culture usually given to perennials will be successful. *M. longifolia* (Syn. *M. elegans*), the WHORL-FLOWER, is the best known species, with its purple flowers in July on plants 2–3 ft. high. *M. coulteriana* (Syn. *M. brevifolia*) is a yellow species also blooming in July, but only growing 9–18 ins. high. *M. persica* (Syn. *M. wallichiana*) is a species bearing white and red flowers from June to August, and grows 2 ft. high. The first and the last species are hardy in the warmer parts of the country.

MORISIA (MEDITERRANEAN CRESS. Nat. Ord. Cruciferæ).—The only species in general cultivation is a pretty dwarf plant with pinnate leaves. It is propagated by root

cuttings in autumn, or by seeds sown in March.

Morisia hypogaea.—This has rosettes of serrated deep green leaves. Flowers bright yellow. Site open. Soil gritty loam. Flowering Period, March to July. Height, 2 ins.

MORMODES.—See *ORCHIDS.*

MORNING GLORY (*Ipomoea purpurea*).—See *CLIMBING AND TRAILING PLANTS.*

MORTAR.

Although it does not often happen that the gardener has to turn into a builder and build his own house, it is distinctly useful for him to be able to do a bit of building, pointing, concrete work or plastering, if occasion should arise, and with the idea of assisting him with the mixing of mortars, concretes, and plasters successfully, we are giving this little article. Taking mortar first there are many grades which come in useful for various purposes. It would, for instance, add greatly to the cost of building a frame if we were to use cement for holding the bricks together, when ordinary common mortar would do, and it would be foolish indeed to waste first-grade mortar on making the foundations of a new hotbed, frame or pit. So our first advice to the gardener is, to study the purposes for which he requires his mortars, concretes, and plasters, and make them accordingly.

Rough Mortar.—Rough mortar is inexpensive to make, and exceedingly useful for many purposes, such as for laying foundations, and other brick or stone laying where quick hardening is not essential. The mixture consists of the following materials, the proportions being bulk for bulk in this and every other case in this article:—

Builders' lime	1 part.
Builders' sand	2 parts.
Fine ground ashes	2 parts.

The sand and the ashes should be mixed together first, and the lime added, after which the mortar is mixed in the usual way, as described under a separate paragraph.

Hair-Mortar.—Where it is desirable for the mortar to stick together rather better than the above mixture does, the addition of hair is advisable, and of the many kinds to choose from none is better than cow hair. The mixture is then made in the following proportions:—

Builders' lime	2 parts.
Builders' sand	4 parts.
Fine ground ashes	4 parts.
Cow hair	1 part.

The precautions described below under MIXING MORTAR when it contains hair should be strictly observed.

First-Grade Mortar.—Where a better mortar than either of the above is required, and one which will in the ordinary course of events speedily harden, the following mixture is advisable:—

Builders' lime	1 part.
Builders' sand	2 parts.

If it is desired that this shall bind even better than it ordinarily does, the addition of one part hair to ten parts of the above mixture will effect this.

Quick-Setting Mortar.—It may be necessary for special reasons to use a mortar which will set very quickly, and to make this is quite easy. To every two barrows of the dry first-grade mortar above, a builders' bucketful of Portland Cement should be added, and the mortar made and used without delay.

Mixing Mortar.—Experienced builders, of course, can mix mortar in any way which pleases them best, but amateurs would do well to give special attention to the correct mixing.

First of all, the materials should be carefully proportioned out and

mixed dry on a hard bed which will not pick up, or better still on a flagged pavement. It is quite impossible to mix the materials by merely turning over the heap once with a shovel. At least three turnings should be given, the material being turned over on to a new piece of ground adjacent to the old heap, but the whole of the heap must be completely moved. It is well to shovel from the outside inwards, not from the inside outwards, as heavier material always collects on the outer margins of the heap.

Where any light material such as hair is used for making the mortar bind better, much care in the mixing is advisable, otherwise the whole of the hair will accumulate in one portion of the pile, generally in the centre, instead of being evenly diffused throughout the whole. The hair should first be thoroughly teased out, to have it as fragmentary as possible, and should then be slowly mixed with the other materials in a dry state. On no account should any water be added, otherwise complete mixing is impossible. When it is seen that the hair is evenly diffused throughout the whole, and there are no bulky lumps of it anywhere, then water can be mixed with the dry material as is described below.

First of all, dig a hole in the centre of the pile with a shovel, and into this pour the water from a bucket a little at a time to give it a chance to be absorbed. When the hole holds water start working from the centre, and stir the material round and round with the shovel until all that water is absorbed; then add more, stir again, add more, and so on until the water begins to penetrate into all parts of the heap. Then get an assistant to spray the whole of the heap with a very fine-rosed can, while you turn it over on to another piece of adjacent ground. When the whole pile has the appearance of thick mud it is time to start working it as builders' labourers do, by driving the shovel into it in an upright position, and gradually working this in and out of the mixture at a slight angle. The mortar produced will then have a slightly shiny appearance on it. It will be soft and plastic, but no longer muddy. The water will be diffused throughout the whole, and all the materials will be evenly mixed together.

As gardeners know to their cost mortar does not keep indefinitely. If a pile is left over the week-end, the outside will have set hard if hot weather ensues. The best way to prevent annoyance of this kind is to put a few boards over the pile and make a hole in the centre, filling this with water. The mortar will then be fit to mix on Monday morning.

Concrete.—Turning now to concrete which is more or less allied to mortar, we have to admit that very few gardeners are able to mix it. The material, however, is so useful, for floors, or bases of pits or frames, or stands for pot plants out of doors, that every gardener should be able to mix it for himself. The following proportions make first-class concrete :—

Hard stone . . .	4 parts.
Builders' sand . .	2 parts.
Portland cement . .	1 part.

The stone should first of all be broken up with a coal hammer, or better still, by means of a light road-mender's hammer, to about walnut size or a little larger. It is then put on a hard floor as in the case of mortar, and the two light materials, sand and cement, are mixed together in a separate pile first of all, and then added to the stone. The whole mass should be turned over three or four times in a dry state, to ensure

even mixing, after which water can be added, and the mass turned and worked repeatedly as before. No more concrete should be mixed than can be used in a day, as it sets very quickly.

Cement for Facing.—For ordinary facing of concrete, brickwork, or other material the following mixture will be good enough :—

Builders' sand . .	3 parts.
Portland cement . .	1 part.

Where, however, it is desirable that the material shall set very hard and last for a much longer period, it is well to strengthen the mixture and make it as follows :—

White sand . . .	2 parts.
Portland cement . .	1 part.

The materials should be mixed dry as before, and very little should be made at a time as the material will set hard in a few hours.

Hydraulic Cement.—It may happen that material which will set under water is wanted by the gardener, especially if he is making a pond or water garden. Various preparations of Hydraulic Cement are on the market, and, of course, it is not our duty here to praise any one more than another. The mixture, however, for facing such a pond is made as follows :—

Hydraulic cement . .	1 part.
Builders' sand . .	2 parts.

A layer of about an inch thick is exceedingly ample, and very often half an inch will be quite sufficient.

Plaster for Backing.—Sometimes roughly-constructed frames need backing or lining, and for this purpose rough plaster is the most suitable material. This is made as follows :—

Common plaster of Paris .	1 part.
Builders' sand . . .	3 parts.

The sand and the plaster should first of all be mixed dry, and the mixture then put gradually into a tub of water of fair size (half a butter tub is suitable), as a large quantity of water is absorbed, and well stirred. The material will swell up, and if there is excess of water this can be quickly run off just before use. Rapid plastering is essential for success, as the material sets almost while the work is being done.

Binding Plaster.—Gardeners who are unused to plastering are almost certain to find that the above mixture does not bind or stick on very well, and although experienced plasterers might be able to make it keep on, some of it is almost certain to fall off when made by amateurs. To obviate this, the addition of hair is advisable, and about one part hair to five, six, or eight parts rough plaster is about right. The hair should be teased out as before, and mixed with the material in a dry state, the mixture then being thrown into water, and applied with the greatest possible speed.

Best Plaster.—In such cases as the insides of greenhouses, which are constantly in view, a better plaster is advisable. This is easily made as follows :—

Best plaster of Paris .	2 parts.
Best white sand . .	6 parts.
Cow hair	2 parts.

The best plaster sets even quicker than common plaster, so that it is necessary to have an assistant constantly standing by turning the mixture over with a shovel and watering it while the worker applies it. A very large mortar trowel is the best tool to use, the material being thrown at the wall with considerable force, and levelled over within a minute of its application. The worker should have a board of the well-mixed plaster put as near the wall as possible ; and the throwing is best done from within a few feet of the wall. A start should in any case be made from the bottom of the

wall, as this is easier for beginners. Plaster will not keep for more than a few hours, so only what can be used at one time should be mixed.

Lime Plaster.—Another kind of plaster is useful for the commoner work, namely, Lime Plaster. This is easily made as follows :—

Obtain a large cask or wooden barrel, and half fill it with cold water. Into this barrel throw some lumps of fresh-burnt quicklime, a few at a time, and stir the water up. Soon the lime will fall and the water will be boiling. When it has cooled down somewhat, add a further supply of the lime, until a thick, sticky paste is formed with no surplus water. Turn this out of the barrel, and work it well with a spade or shovel in the same way as mortar, applying it with a mortar trowel as before.

If the addition of hair is desirable to make it bind better, the lumps of lime should be lightly slaked with water first of all until they fall to a fine powder. They should then be mixed with the hair in the following proportions :—

Slaked lime (dry) . .	5 parts.
Cow hair	1 part.

The thoroughly incorporated mixture should then be dropped in the water as before, and well stirred until a thick, sticky paste is formed, and this is applied with a mortar trowel in the usual way.

If the mixture is not made in a barrel a great deal of water is wasted and a certain amount of lime as well, since the water has to be largely in excess of the lime to obtain the desired paste.—E.

MORUS.—For the best species see *TREES*.

MOSS.

There are various kinds of mosses, some useful to the gardener and others useless. Moss as a weed is treated in our article on *WEEDS*. PEAT-MOSS LITTER is dealt with in our article on *HORSE MANURE*, while SPHAGNUM MOSS is referred to in our article on *ORCHIDS : POTTING AND WATERING OF*.

See also *WEEDS*.

MOSS ROSE (*Rosa gallica muscosa*).—See *ROSE SPECIES*. For best varieties see *ROSE CLASSES*.

MOSS RUSH (*Juncus squarrosus*).—See *JUNCUS*.

MOTHER WORT (*Leonurus Cardiaca*). See *LEONURUS*.

MOTHS.

A number of interesting and beautiful moths are mentioned in the article on *INSECT PESTS*. Moths do a very great deal of damage indirectly, as also do butterflies, by laying eggs which hatch out into caterpillars. Probably two of the worst moths are the *Heart and Dart Moth* and the *Turnip Dart Moth*.

In order to prevent the caterpillars being hatched, it is advisable to catch as many of the moths as possible. These moths fly about on still summer nights, and an ingenious method of destroying them, which does not occur to most people, is to put a few lighted candles about the garden where the moths seem fondest of flying. The moths are attracted by the lights and fly into them, thus committing suicide. They can, of course, be caught with a butterfly-net, but most gardeners have something better to do than to be dashing about the pleasure-grounds after a few moths.

MOUNTAIN CHERRY (*Prunus angustifolius*).—See *CLIMBING AND TRAILING PLANTS*.

MOUNTAIN CLEMATIS (*Clematis montana*). — See *CLIMBING AND TRAILING PLANTS*.

MOUNTAIN CUDWEED.—The Kew name of *Antennaria dioica*. See *ANTENNARIA*.

MOUNTAIN LIMESTONE.—See under LIMESTONE in *ROCKWORK*.

MOUNTAIN MAGNOLIA (*Magnolia acuminata*).—See *TREES*.

MOUNTAIN MAPLE (*Acer spicatum*). See *TREES*.

MOUNTAIN PARSLEY (*Cryptogramme crispa*). — See *FERNS AND FERN GARDENING*.

MOUNTAIN PINE (*Pinus montana*).—See *TREES*.

MOUNTAIN SORREL (*Oxyria digyna*. Nat. Ord. Polygonaceæ).—This, a hardy herbaceous perennial of very easy culture, should be distinguished from the *SORREL* (*Rumex*) grown and used as a salad and vegetable, upon which we devote a separate article. *O. elatior* is now no longer recognised as a species, but is the variety *elatior* of the species under notice, while *O. reniformis* is a synonym of *O. digyna*. It is a plant of no importance, bearing only insignificant greenish flowers in June, on plants 6 ins. high.

MOUNTAIN SPINACH.—See *ORACHE*.

MOUNTAIN WOLFSBANE (*Ranunculus Thora*).—See note at end of *RANUNCULUS*.

MOUSE-EAR CHICKWEED.—A popular name for *CERASTIUM*, which see.

MOUSE-EAR HAWKWEED (*Hieracium Pilosella*).—See *HAWKWEED*.

MOUSE GRASS (*Aira caryophyllea*).—See *AIRA*.

MOUSETAIL GRASS (*Festuca Myuros*). See *FESTUCA*.

MOUTAN (*Paeonia Moutan*). — See *SHRUBS*.

MOVEMENT OF PLANTS.—See *PLANT PHYSIOLOGY*.

MOWING.—See *LAWNS AND THEIR MANAGEMENT*.

MOWING MACHINES.—See *GARDEN APPLIANCES*.

MUEHLENBECKIA. — For the best species see *CLIMBING AND TRAILING PLANTS*.

MUEHLENBERGIA (AMERICAN DROP-SEED GRASS. Nat. Ord. Gramineæ).—This is an unimportant genus of hardy grasses of no garden value.

MUGWORT.—See *MEDICINAL HERBS*, and under ARTEMISIA in *SHRUBS*.

MULBERRY.

This is best grown as a standard, and can be bought in a fruiting condition; where young trees are planted they take six to eight years to arrive at a fruitful state. In planting, it is material to preserve all the roots, and not to cut them at all, or the tree may be checked for years. It prefers a rich warm soil, and does not succeed in clay or heavy land. It grows into shape without pruning.—G. B.

See also MORUS in *TREES*.

MULCHING.

Mulching is the operation of putting a layer of soft, moist material over the surface of the soil for the purpose of conserving the moisture. It is quite distinct from top-dressing, upon which we give a separate article, as the object of mulching is not mainly for the purpose of increasing the food supply of the soil, or giving additional food to plants,

but merely to protect the surface soil and the roots of the plants from undue evaporation. In the summer months, especially on light soils, evaporation is very rapid, and even on the strong soils, the roots of the plants get dry very quickly, although hoeing and cultivating may be persistently done. The object of mulching, then, is to check this evaporation, to retain the soil water in the soil for the plants to use, and at the same time to keep the roots of both flowers and vegetables cool and vigorous even in the hottest of hot weather.

Mulching Materials.—Recognising, then, the purposes of mulches, many materials are available which are quite unsuitable for top-dressing. The mulching materials used need not be exceedingly rich, so long as they have the power of retaining moisture, and this opens a wide range of material for the purpose. The selection of the best mulching material must depend more or less on the kind of soil above which it is to be spread. For poor, dry soils it is advisable to use fresh or moderately fresh cow manure, and the greener this is the better. For soils rich in plant food, and which are on the strong side, the use of such a sticky manure would be quite undesirable. What is known as old hotbed manure would be greatly preferable in this case, and that which is most mild in action is the material which is about twelve months old. Where, however, a supply of that material is not available, month-old manure from the stable or farmyard can be used without any detrimental effect, though the use of manure which is fresher than four weeks old may produce some bad results. The residue from liquid manure tanks is specially useful for application as a mulch to very light, sandy soils, but care must be taken that this does not set into a hard layer with a skin on, otherwise it will be valueless as a mulch.

A much cheaper material for use as a mulch on soils which are not over light is found in lawn mowings. These should be fresh, and put on in a thick layer of not less than 3 ins., as they soon rot away almost to nothing. Where, however, the soil is very light, it would be a mistake to apply the mowings in a fresh state, as they will go to nothing on the first hot day. In that case it would be well to use them after allowing them to rot in a heap in the manner described in our article on *Lawn Mowings*. This material can be spread on in a layer about 2 ins. thick, and will be exceedingly valuable as a mulch.

The use of fresh leaves as a mulch is not desirable, but on the other hand, for mulching flower borders, year-old leaf-mould is exceedingly valuable, and a much thicker layer of this should be used for mulching purposes than would be applied as a top-dressing. The material should be cut down from the leaf-mould stack with a sharp spade, and should not be cut too small, otherwise it will be less valuable. It is then spread on with a fork in the usual way. The use of this leaf-mould on the flower borders is greatly preferable to the use of farmyard or stable manure for two reasons. First, on account of it being practically inodorous, and thus quite free from objection in that direction; and secondly, because the birds will not peck it, scratch it out, or throw it about in the same way as they would manure, on account of the fact that it contains very few or no grubs.

Various kinds of fibre, such as cocoanut fibre refuse, can also be used for mulching, provided that

small areas only are to be undertaken. The results obtained from the use of these fibres are usually excellent, but, of course, their great cost prevents them being regarded as economic materials.

What Not to Use.—It may be well to draw attention to some materials which are quite unsuitable for use as mulches, and these materials happen to be far cheaper than any of those which we have named, as well as being more easy to obtain in large quantities. Special care should be taken to avoid such an objectionable mulching material as road scrapings, or dried road sweepings, and we are astonished to find how generally the use of these materials for the purpose named is advised. The reason why we condemn them is simple: Road sweepings, as soon as a heavy storm of rain falls upon them, set into a hard, cakey material which rapidly cracks and lets out more moisture than even the soil would do if it cracked. It stops air from getting to the roots of the plants and checks healthy growth, which is, of course, a very serious item to consider. Moreover, road sweepings are usually full of all manner of objectionable weed seeds, which after a shower of rain and a bit of sunshine will rapidly germinate, and cause great trouble. Road sweepings are perfectly admissible as a lightening material for the soil if dug in deeply, but for purposes of mulching they are not only useless, but harmful.

Another material the use of which is highly objectionable as a mulch is found in pond mud, which is obtainable in large quantities during most dry summers. The material is exceedingly rich both in vegetable and animal matter, and its use as a mulch is most tempting. Those inclined, however, to apply it should first of all arrange to clear out a piece of water when it is reasonably low, and should make a stack of the material in some spot as sunless as possible. In a short time a hard, rock-like cake will form on the surface, which is quite impenetrable to roots of plants and to the air. This material will get harder and harder as the weeks pass. In contact with hot sun on the surface of the soil the cake will form harder and quicker. Thus the reason of the advice not to use this material is almost obvious. As we have already pointed out, pond mud is very rich, but its use, even for digging into the soil, should be most carefully controlled, as it may prove to have a far greater stimulating effect on the plants than is expected or desired.

Yet another material which is objectionable as a mulch is what is known as sewage refuse. This material is produced by the weathering of sludge cake from sewage works, and is in itself a very rich and desirable manure, and should be used for that purpose on light, sandy soils. As a mulch, however, it is inclined to set hard and cakey on the surface, and as a rule it is objectionable on account of its odour.

Turning now to vegetable materials which are objectionable for use as mulches, we have already mentioned that this is the case with fresh leaves. Another material of a similar nature, which is more objectionable still, is found in pine needles, which, in contact with the soil, lose some of their oily, resinous matter, and serve to poison it. The gardener will observe that very few subjects succeed under pine trees where a mulch of this material, namely, fallen pine needles, is so abundant, and thus should not be deceived by frequent advice given

in the gardening papers to make use of these needles as a mulch for his plants. As we have pointed out in another article, pine needles are extremely valuable for starting a garden fire, but that is about the limit of their use.

Two other vegetable materials which are objectionable for use as mulches are found in peat or moss. The use of the latter is, of course, wholly objectionable, but Rhododendrons may be successfully mulched by the application of fresh peat from bogs or moors. For other crops, however, peat as a mulch must be regarded as distinctly objectionable, on account of the acid in it, which it will rapidly convey to the soil. A method of sweetening peat for use as a manure for non-ericaceous crops exists, but as a rule this is too expensive to have much practical value.

Turning now to mineral materials which are objectionable to use as a mulch, we must point out that most of them come within this category. Flue Dust, Soot, Wood Ashes, Ground Bones, and most other fertilisers, may be used as a top-dressing, in combination with other composts or manures, but not as mulches. Their purpose is for feeding, rather than conserving moisture. One material, however, which may be mixed with the surface of the soil for the purpose of enabling it to retain its moisture is Salt, used at the rate of about 1 oz. to the sq. yd., or Magnesium Sulphate may be used at a rather less rate for the same purpose. These materials must not, however, be regarded strictly as mulches, but rather as physical additions to the surface of the soil.

Preparation for Mulching. — Mulches will be of little value if applied to hard-baked soils which have not had any previous preparation. It would be well in every case to loosen the surface soil thoroughly with a hoe or cultivator, and if it is at all dry, to soak it well with water before applying any mulch. A deep, long-toothed cultivator is advisable for use on allotments and in the kitchen garden, but an ordinary Dutch hoe is quite satisfactory for border work.

The thickness of mulches varies, of course, with the length of time they are to last, but 3 ins. or 4 ins. is about the best and most satisfactory. Thicker mulches may chill the roots, and thinner mulches will be practically useless.

Mulches require to be renewed several times during the summer, and the old mulch can then be raked off, thoroughly soaked with water or liquid manure, and applied to a smaller area. About four renewals will be necessary for an average season, but many more if hot weather starts in May and continues until the end of the autumn.

E. T. E.

See also *ORCHARD : MAKING AND MANAGEMENT OF*, and under GENERAL MANAGEMENT in *VEGETABLES : GENERAL CONSIDERATIONS*.

MULCHING MATERIALS. — See *MULCHING*.

MULE PINK (*Dianthus hybridus*).— See *DIANTHUS*.

MULGEDIUM.—Now included in the genus *LACTUCA*.

MULLEIN (*Verbascum*. Nat. Ord. Scrophulariaceæ).—Over a hundred species of Mullein have been described, many of them quite worthless, and of botanical interest only. In the present article we confine ourselves to the Biennial Border Species and Perennial Border Species, omitting the Annuals and Shrubs as being outside the scope of the present work. The common Mullein (*Verbascum Thapsus*) is a useful medicinal plant, and reference

should be made to our article on *Medicinal Herbs* for further particulars.

Biennial Border Species.— It is difficult, of course, to advise definitely as to the best varieties when there are so many to choose from, but the following selection of Biennials includes some of the choicest. They are all easily raised from seeds sown in good garden soil in an open position from April to June, and may be treated in the same way as other ordinary hardy biennials.

Verbascum Blattaria.—This bears yellow, or sometimes cream flowers from June to September, and grows 2–4 ft. high.

V. Chaixii. — This useful sort bears yellow flowers from June to September, and grows 1 yd. high.

V. olympicum. — This attractive sort bears golden-yellow flowers throughout the summer,and averages 5–8 ft. high.

V. phlomoides.—This is similar to *V. Chaixii.*

V. rubiginosum.—This is a very attractive sort with yellow flowers deeply tinted with red. It blooms from June to September, and grows 2–4 ft. high.

V. spectabile.—This useful sort bears yellow and purple flowers from June to September, and grows 2 ft. high.

V. Thapsus (Common Mullein). —This is a well-known yellow sort blooming throughout the summer and early autumn, and growing 2–8 ft. high.

Perennial Border Species.—These are of the easiest cultivation in any good garden soil, and are exceedingly suitable for the perennial border, shrub border, or the wild garden. They can easily be increased by division of the roots in the autumn, by cuttings in the summer, and abundantly by seeds sown from March to May. The best time to plant is in March. Of the many sorts that have been described we recommend the following :—

Verbascum cupreum.—A synonym for *V. phoeniceum,* which see.

V. ferrugineum. — This bears flowers of a rusty-brown colour in long spikes from May to August, and grows 1 yd. high.

V. nigrum.— This bears small yellow flowers with purple hairs on the stamens. The long spikes are produced from May to September on plants 2–3 ft. high.

V. orientale.—This is a branching sort,producing yellow flowers in June and July, on plants 2 ft. high.

V. ovalifolium (Syn. *V. formosum*). —This most attractive sort bears large orange flowers from July to September, and grows 1 ft. high.

V. phoeniceum (Syns. *V. cupreum, ferrugineum,* and *puniceum*).—This bears purple flowers on slender stems from May to August, and grows 2–3 ft. high.

V. pinnatifidum (Syn. *V. bipinnatifidum*).—This is the least attractive sort of any described. It bears yellow flowers in scattered clusters during May, and grows about 1½ ft. high.—J. F.

New Varieties.

Verbascum International. — This bears buff-apricot flowers, and grows 6 ft. high.

V. Warley Rose.—This bears rose flowers with chocolate spots and violet stamens, on plants 5 ft. high.

MUSHROOM SPAWN: MAKING.

It often happens that one wants to make one's own mushroom spawn, hence the following hints will be useful:—

Collect together a quantity of fresh horse droppings, fresh cow manure, and maiden loam. Weigh up equal proportions of the two manures and one-eighth part of the two of the loam. Break up the droppings with a small fork, spread on them a layer of cow dung and scatter the soil on this. Proceed in the same way till all the manure has been used. Then make a hole in the centre of the heap in the same manner as is done for mixing mortar or concrete (see article on *MORTAR*), and fill with strong liquid manure from the stable yard. Work the heap in exactly the same way as is done in mortar making, but see that the mixture is not made too wet or sloppy. After thorough mixing fill shallow seed boxes previously lined with newspaper with it, and allow to become half-dry. Then insert pieces of spawn (found in heaps of old rotted dung) into the bricks or spawn flags, and place in a warm place for the spawn to work. After a day or two turn out the spawn from the boxes, cut up into convenient-sized bricks, and store in a cool, dry place till required for use.

MUSHROOMS.

The cultivation of these is not nearly as general as it should be, considering how simple it is. Good fresh horse-droppings are the chief essential to successful cultivation, and where a regular supply of these from corn-fed horses can be secured, there is no valid reason why, with a little perseverance, good crops should not be had at all seasons.

Mushrooms may be grown during the winter months in any warm shed or cellar, but during the warmer period of the year, beds made up in a shady spot in the open air will be most likely to give crops of the best quality.

Making the Bed.—Gather the droppings (minus the long straw) from the stables each morning, until sufficient has been obtained to make a bed of the desired size. Perhaps the size most suitable is a bed 4 ft. wide and 6–8 ft. long, allowing a depth which, when fully settled, will not be less than 3 ft., such a bed retaining the necessary heat over a period sufficiently long to ensure the spawn working satisfactorily.

This manure must be laid out thinly under the cover of a shed where rain will not reach it, until sufficient has been got to make a start, after which it should be put into a conical heap to ferment, turning it thoroughly every third morning in order that the very rank steam may escape. After three such turnings the bed may be made.

When making up the bed, should any doubts exist as to quantity of manure being adequate, rather than risk failure the addition of a sixth part good fibrous loam may be made, care being taken to mix this thoroughly with the manure.

The bed should be made moderately firm, but not beaten hard, and as soon as the temperature of the mass, which at first is bound to be pretty high, is reduced almost to 75° F., or 80° F., spawning or planting may be done.

It is most important that the

spawn used should be in a perfectly fresh condition, this being easily ascertained by breaking it in pieces. If a small white thread-like substance is seen to be permeating the whole brick, it will be quite safe to use; but where the mass has the appearance of dried manure the sample should be rejected. Pieces of spawn about the size of a bantam's egg are generally used, burying these about 2 ins. below the surface, at a distance of 6–8 ins. each way.

A few days later cover the bed to a depth of 2 ins. with finely sifted loam, making the surface even, and beating down firmly with the back of a spade. Place a layer of straw or hay over the bed to prevent rapid evaporation of heat and moisture, also to ensure increased warmth should the temperature show signs of dropping too suddenly.

About six weeks later the covering may be carefully removed and the bed examined. If very dry, a slight watering with tepid water may be given, and from this time forward mushrooms may be expected.

Beds in bearing should be frequently syringed overhead and round about, always using tepid water, and after syringing have the covering material replaced.

Pull up all mushrooms as soon as they attain a fair size, in any case before the under side of the specimen gets really black, always filling in the holes thus made with soil or manure.—F. R. C.

["Spent" beds may frequently be revived by a good soaking of salt water or a solution of nitrate of soda.—EDITOR.]

MYCORHIZA.

Many plants, including heaths, orchids, and trees belonging to the Natural Orders *Coniferæ* and *Cupuliferæ*, form an association between certain of their rootlets and fungi which is known as *Mycorhiza.* In the case of forest trees the mycorhiza is external, on the roots, and forms a sheath of fungal hyphae round the rootlets, and these hyphae function instead of the root-hairs. In the case of orchids, the fungus is internal; it enters the cells and feeds on the stored starch in the outer layers. In the innermost layers the fungus is subsequently digested and yields food for the host plant. The degree of intimacy between the fungus and the host plants varies greatly in different classes of plants; in orchids and others where the association is very close, seedlings cannot be raised unless the right fungus be present in the soil.—A. D. C.

MYOGALUM.—Now included in the genus ORNITHOGALUM.

MYOSOTIDIUM (Nat. Ord. Boraginaceæ).—One species of this little genus is of considerable importance as a half-hardy herbaceous perennial. This, *M. nobile*, popularly known as the CHATHAM ISLAND FORGET-ME-NOT, bears large blue flowers, the margins of which are white. It flowers in April and May, and grows about 1½ ft. in height. Culture is easy if moist,

rich loam is provided in a warm, sunny spot, but in cold districts it should be protected by a covering of straw in the winter. It is best raised by summer-sown seeds.

MYOSOTIS.—This genus is treated under its well-known name *FORGET-ME-NOT.*

MYRIAPODA.—See under MILLEPEDES in *INSECT PESTS.*

MYROBALAN PLUM (*Prunus cerasifera*).—See *TREES.*

MYRRHIS.—See *SWEET CICELY.*

MYRSIPHYLLUM.—See *SMILAX.*

MYRTLE (*Myrtus.* Nat. Ord. Myrtaceæ).—The genus Myrtus is one containing many greenhouse and half-hardy shrubs prized alike for their flowers, foliage, and sweet scent. They thrive in a sharply drained, peaty loam, with leaf-soil added, and are propagated by cuttings. The height averages 5–15 ft.

Culture.—Cuttings of current year's growth, half-matured, will root easily if given a little bottom heat, or kept rather close in a warm house. As the myrtles love a moist, warm atmosphere, the syringe should be freely used throughout the summer months.

USES.—Apart from its ornamental value, the common myrtle is useful economically. A fragrant toilet oil is obtained from the berries, which have also carminative properties, and the leaves and bark are sometimes used for tanning in the East. The plants make handsome wall shrubs in the milder parts of the country, and are useful for sub-tropical work.

Varieties.—The best are Communis, Luma, tenuifolia, and Ugni.—J. L. G.

See also *SHRUBS.*

MYRTLE GRASS (*Acorus Calamus*).—See under SWEET FLAG in *WATER GARDEN: PLANTS FOR THE.*

MYRTUS.—See *CLIMBING AND TRAILING PLANTS, MYRTLE,* and *SHRUBS.*

N

NAPHTHALENE.—See *Soil Fumigating.*

NAPLES GOURD.—See *Ornamental Gourds.*

NARCISSUS BULB FLY.—See *Insect Pests.*

NARCISSUS SPECIES (Nat. Ord. Amaryllidaceæ).—A few notes on some of the best of these may be of interest to bulb enthusiasts. They are all of easy culture and quite hardy, blooming in the spring-time. The height averages 3–18 ins.

Narcissus Backhousei.—This is of garden origin, and has given rise to many varieties. It is a lovely pale yellow or sulphur sort.

N. Barri (Barr's Hybrid Daffodil). — This also is of garden origin, and is available in many varieties. In colour it varies from orange to the palest yellow.

N. biflorus.—This is a pretty white sort worthy of more extensive culture.

N. Bulbocodium (Hoop-Petticoat Daffodil).—This is a very dwarf, early blooming species. The best varieties, ranging in colour from orange to palest lemon yellow, are *citrinus, conspicuus, Craellsii,* and *monophyllus.*

N. Burbidgei.—This is of garden origin, and has given rise to numerous garden varieties. It is a white flower marked red and yellow.

N. cernuus.—This bears pretty pale yellow or white flowers. Its variety *plenus* is difficult to grow.

N. cyclamineus (Cyclamen-flowered Daffodil).—This bears pale yellow flowers with a darker trumpet.

N. gracilis.—This is a tall, yellow species, of which the variety *tenuior* bears pale, almost white flowers.

N. Humei.—This is another sort of garden origin which has given rise to very numerous garden varieties. It bears attractive pale yellow flowers.

N. incomparabilis. — This has given rise to a host of garden varieties, and bears chiefly white or yellow flowers. Its varieties *aurantius plenus,* the popular Orange Phœnix, and *sulphureus plenus,* the well-known Sulphur Phœnix, bear double flowers.

N. intermedius.—This, and its variety *major,* bear light yellow flowers. The variety is the stronger grower.

N. Johnstoni.—This bears attractive flowers of the palest yellow. It has been found useful by hybridists.

N. Jonquilla.— See article on *Jonquils.*

N. juncifolius (Rush-leaved Daffodil). — This is a useful species with rush-like leaves.

N. Leedsii (Leeds' Hybrid Daffodil).—This is of garden origin, and has given rise to a host of varieties. It bears white and yellow flowers.

N. Macleayi.— This, and its varieties *Nelsoni* and *tridymus,* bear white and yellow flowers; those of the latter emitting a pleasant scent.

N. major.—This is a tall, early flowering daffodil with yellow flowers.

N. maximus.—This is a lovely, large flowered, yellow species which should be grown by all.

N. minor.—As its name implies, this is a dwarf-growing sort. The varieties *minimus* and *nanus* are the best, and bear yellow flowers in the early spring.

N. moschatus (Musk Daffodil). —This is a favourite white species,

the flowers of which emit a musk-like scent.

N. muticus.—This is a yellow species which is distinct and useful.

N. odorus (CAMPERNEL).—This is an important species with sweet-scented, yellow flowers. The variety *minor* is known as the SMALL JONQUIL, and *minor plenus* is known by the trade as QUEEN ANNE'S DOUBLE JONQUIL, while *plenus* is popularly called the DOUBLE CAMPERNEL.

N. Poetaz.—This is an important group of hybrids. The best half-dozen are *Aspasia, Elvira, Ideal, Irene, Klondyke,* and *Profusion.* These are various shades of white and yellow. The first three and the last are white, with a yellow cup.

N. Poeticus (POET'S DAFFODIL, POET'S NARCISSUS, PHEASANT'S-EYE NARCISSUS, etc.).—This is a very favourite white sort, and has given rise to numerous garden varieties. Some of the best are *ornatus, poetarum, recurvus,* and *tripodalis.* The first is very useful for early flowering.

N. Pseudo-narcissus (COMMON DAFFODIL).—This and its numerous forms are described in our article on *DAFFODILS.*

N. Tazetta (POLYANTHES DAFFODIL).—A very large number of yellow and white varieties of this are available. Some of the best are *aureus, Bertolonii, canariensis, citrinus, Cypri, dubius, etruscus, italicus, lacticolor, panizzianus, papyraceus* (the well-known PAPER WHITE NARCISSUS), *patulus, polyanthos,* and *syriacus.*

N. triandrus.—This is the popular ANGEL'S TEARS, with white or yellow flowers in the early spring. The best varieties are *albus, concolor, pallidulus,* and *pulchellus.*

NARDOSMIA.—Now included in the genus *PETASITES.*

NARDOSTACHYS.—See *SPIKENARD.*

NARDURUS.—Now included in the genus *FESTUCA.*

NARDUS (MAT-WEED. Nat. Ord. Gramineæ).—This is a small genus of hardy grasses quite unworthy of cultivation. *N. stricta* may be seen at Kew.

NARROW-LEAVED SPINDLE TREE (*Euonymus americanus angustifolius*).—See *CLIMBING AND TRAILING PLANTS.*

NARTHEX.—Now included in the genus *FERULA.*

NASTURTIUM (*Tropaeolum.* Nat. Ord. Geraniaceæ).—It is a pity the genus Tropaeolum has received the popular title of Nasturtium, because this name belongs to the Watercress, and Tropaeolum is not more difficult to pronounce or remember than Nasturtium. The two Peruvian species, *T. majus* and *T. minus,* have for a great many years been among the most popular of garden plants. In the hands of florists and hybridists they have been made to produce a wide range of colour varieties, and some with dark, and others with golden, green, or variegated foliage.

Culture.—This is quite a simple matter. Seeds may be sown in gentle heat in March and the seedlings planted 1 ft. apart, but this method is by no means necessary, as seeds sown out of doors in April about 10 ins. apart will provide for an ample display. A sunny position and poor, light soil are necessary to obtain plenty of bloom; in rich, heavy soil foliage is developed at the expense of flowers. The young leaves of *T. majus* and *T. minus* are a useful addition to the salad bowl. The best sorts are:—

Tropaeolum Lobbianum.—This is a handsome climber with ivy-like leafage and flowers ranging from yellow to crimson in colour. Its height is 6 ft. or more.

T. majus (Syns. *T. elatum, T. hybridum, T. quinquelobum, T. repandifolium* and *T. Schillingii*).—This is the popular CLIMBING NASTURTIUM which flowers throughout the summer, and often grows 6–8 ft. high. There are numerous named and colour varieties, the colours ranging from palest buff to the most brilliant scarlet and deep crimson. Some are self-coloured. Others are spotted.

T. minus (Syns. *T. dentatifolium* and *T. pulchellum*).—This is the popular DWARF NASTURTIUM growing 6–15 ins. high. There are variegated and dark-leaved, as well as light and deep green-leaved forms, and the colour range among the flowers is even wider than in the tall growing varieties described in the last paragraph. The *Tom Thumb* strain is very compact. So well have seedsmen selected all the variations that each one comes almost a hundred per cent. true from seeds. The plants bloom with remarkable freedom from July onwards till frost cuts them down.

T. peregrinum (Syns. *T. aduncum, T. canariense,* and *T. Smithii*).—This is the well-known CANARY CREEPER, a climber that is suitable for arches, as it will grow 12 ft. high. Its flowers are small, numerous, and yellow; they are like tiny golden birds ready for flight, and are produced freely throughout the summer.

See also *SALAD PLANTS*, and under TROPAEOLUM in *CLIMBING AND TRAILING PLANTS*.

NATIVE GUANOS.—See *GUANO*.

NATSU GUMI (*Elaeagnus pungens*).—See *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

NATURAL MANURES.—See *MANURING: PRINCIPLES OF*.

NATURALISING BULBS.

Naturalised bulbs look far more lovely than bulbs grown in any other way, and on account of this form of gardening coming to the fore, we are compelled to devote a few notes to the subject here.

The most suitable site for naturalising bulbs is some lightly shaded woodland glade. Lawns in full view of the house are quite unsuitable, since they cannot be mown till the bulbs have completely died down, and, of course, look somewhat untidy in the later stages.

Provided the soil is fairly light, no special preparation is required. To attempt to plant in any definite-shaped beds or clumps is to mar much of the beauty of the naturalised specimens. Far better to take the bulbs in handfuls and scatter them in all directions, planting them where they fall.

As regards the actual method of planting, if a proper bulb planter (sold by many horticultural firms) is available, by all means use one. If not, use a trowel, lifting the turf, putting in the bulb, replacing the turf and making very firm.

The bigger bulbs in the initial stage of planting should be set about 1 ft. apart to allow for the young bulbs produced to grow up without undue crowding. The smaller bulbs may, of course, be planted much closer up to about 3 ins. apart each way.

Planting of bulbs for naturalising should be done as early as possible. The present writer considers August and September the ideal time, but certainly the work should not be delayed after the end of October, otherwise the bulbs do not get a fair chance to root in the soil before the winter comes on.

It is unnecessary in many cases to purchase new bulbs for naturalising. Those which have been grown in pots or in fibre, those which have been forced, and those used for spring bedding in the borders are all suitable for naturalising. The

best mode of procedure is to shake the soil from these, and lay them in at once in the woodland just as they are, with their green tops on as soon as they are finished with. The tops then die down quite naturally, and the bulbs have a splendid start for the following year. Once planted the bulbs should not be disturbed for at least six years, an annual top-dressing of leaf-mould in the autumn being all they require.

As regards suitable bulbs to plant, the range for choice is very great, including all the hardier bulbs. Naturally one avoids naturalising the choicer Lilies and such like, on account of the very noble appearance of these in the flower borders.

E. T. E.

NAUMBURGIA.—Now included in the genus *LYSIMACHIA*, which see.

NAVARRETIA.—Now included in the genus *GILIA*, which see.

NAVELWORT.—A name applied to *OMPHALODES*, which see. It is also applied at times to the genus *COTYLEDON*, popularly known as PENNYWORT.

NECKERIA.—Now included in the genus *CORYDALIS*, which see.

NECTARINE SHOT-HOLE DISEASE. See under PEACH SHOT-HOLE DISEASE in *PEACH DISEASES*.

NECTARINES.—See *PEACHES*.

NECTARINES AND PEACHES: Indoor Culture.—See *PEACHES*.

NECTARINES AND PEACHES: OUTDOOR CULTURE. — To grow Peaches and Nectarines out of doors the protection of a wall or fence is necessary, and for preference one facing south or south-west.

Although they will grow elsewhere, yet to secure perfect well-flavoured fruit the trees need all the sunshine available, and unless attention can be given to cultural details similar to those grown under glass as regards disbudding, thinning, etc., the space afforded them would be much more profitably employed by being devoted to the choicer Pears and Plums.

Nectarines and Peaches are amongst our earliest fruits to flower, and consequently, if exposed, are extremely liable to injury from early spring frosts, therefore some protection is necessary either in the form of a permanent coping, the temporary use of blinds, or some substitute such as a double thickness of fish netting.

If the latter plan is adopted, means must be afforded so that the blinds may be drawn up during the day when the weather conditions are favourable, to allow the blossoms to become perfectly developed and fertilised, either naturally by the bees or artificially by a sharp tap of the trees about the middle of the day or during sunshine when the pollen is dry and flies.

Though the outlay is greater, a permanent peach case or shelter is much the best, and can be erected by the use of iron standards at every 12 ft., connected with a top rail, which should be 9 ins. lower than the top of the wall to allow a good fall to the movable glazed lights, which are supported between the latter and the wall.

A convenient width for the whole structure when complete is 3 ft. The wall, as a saving of labour for years to come, should be wired as close to the stone as possible to give the trees the benefit of the warmth, but leaving sufficient space to allow of the tying material being placed easily and quickly at the back of them. An ideal fitting to the whole is the use of a wooden trellis to walk upon, and the fixing of guttering and down pipes for collecting, and the use of rain water which would otherwise go to waste.

The iron supports may be made use of also for outdoor Tomatoes or for training Cordon Pears or other fruit against; if so, temporary sticks should be affixed to them to prevent the growth coming in contact with the iron. The best of fruit may be obtained under such a structure equal to that grown under cool house treatment, and, generally speaking, with additional advantages, since during the resting period the trees are permanently exposed to the elements, with the exception of the roof covering, though if this last is made in sections, as previously mentioned, it can also be removed, and at no season of the year is the attention of ventilating needed. Perhaps the greatest boon of all is the rendering of the trees practically immune from the attacks of leaf-curl or peach blister.

In a wet, sunless season the trees and fruit are greatly benefited, besides allowing work to be done during wet weather, whilst in hot, dry summer weather the roof may be shaded over to protect the foliage from the scorching rays of the sun. These advantages therefore compensate for the extra labour entailed in watering and syringing, which after all are necessary with those unprotected to secure the best results.

The type of tree usually employed is the dwarf fan-trained. These should be planted 15 ft. apart, and for the first few seasons the most may be made of the space by planting standard fan-trained trees in between.

Exactly the same remarks apply to planting, training, and other cultural details as to those grown under glass, and the quality of the fruits will largely depend upon judicious thinning, feeding, and mulching, also on the exposure of the fruit to the sun. By selecting early mid-season and late varieties a long season is maintained.

With outside trees syringing must be relied upon to combat insect pests, and insecticides properly diluted according to the makers' instructions should be applied when the weather is dull, and preferably towards evening so as to allow the foliage to remain wet for a longer time. Earwigs and woodlice, two disagreeable enemies, have a great dislike to moisture, and frequent syringings of the trees will do much to keep them away. Trapping of these pests may also be carried out by means of short lengths of bean stalks, and small pots filled with dry hay put down at night and emptied in the morning. After a heavy watering, woodlice can often be killed in great numbers crawling up the wall. Birds, wasps, and bees also prove troublesome at times, and necessitate protection by netting tiffany, muslin, etc.—E. B.

NECTAROSCORDUM.— Now included in the genus *ALLIUM*, which see.

NEEDLE, ADAM'S (*Yucca gloriosa*).— See *YUCCA*.

NEEDLE FURZE (*Genista anglica*).— See *SHRUBS*.

NEILLIA.—For the best species see *SHRUBS*.

NEMATUS.—See CURRANT AND GOOSEBERRY SAWFLIES and LARCH SAWFLY in *INSECT PESTS*.

NEMESIA (Nat. Ord. Scrophulariaceæ).—This is a genus of half-hardy annuals, or, more correctly, half-hardy perennials which are treated as half-hardy annuals. They are useful either for summer bedding or for greenhouse decoration. They may be successfully raised by sowing in heat in the usual way for half-hardy plants, but must be well hardened off in a cold frame prior to planting out. The following are the best species of this brilliant genus :—

Nemesia floribunda (Syn. *N. affinis*).—This bears yellow and white flowers from July to August, and averages 12 ins. in height.

N. pubescens.—This is pure white, but otherwise similar to *N. floribunda*.

N. strumosa. — This, and its variety *Suttoni*, are quite the most popular of all with their brilliant scarlet, orange, red, yellow, or many-coloured flowers from the end of June onwards into the autumn, on plants 9–12 ins. high.

NEW VARIETIES.

Nemesia Marsden Jones. — This bears rich orange flowers, which are marked with crimson.

N. Orange Prince.—This bears bright orange flowers with a violet blotch. It grows only 6–8 ins. high.

NEMOPHILA (CALIFORNIAN BLUE-BELL. Nat. Ord. Hydrophyllaceæ).—*Nemophila insignis* would rank very high if a census were taken with a view to gauging the popularity of hardy annuals, but the other members of the family are not held in such high esteem. An autumn sowing, and also one or two spring sowings are desirable, but thin sowings in light soil, followed by thinning the seedlings to 6–12 ins. apart, are essential if the plants are to develop their full beauty. As a rule they are sown thickly and left unthinned, consequently they remain stunted and soon pass out of bloom. One well-grown plant of *Nemophila insignis* will occupy nearly 9 sq. ins. of ground. We briefly describe the three best species below :—

Nemophila insignis.—This has a blue flower with a white centre, and will bloom freely throughout the summer. There are numerous colour variations offered by seedsmen, and there are large-flowered or grandiflora strains. The foliage is quite elegant, and the plant grows 9–15 ins. high.

N. maculata (Syn. *N. speciosa*).—This is a white sort, with a purple spot on each of the five corolla lobes. The flowers are large for the size of the plant, and are freely produced throughout the summer. The height is 6–8 ins.

N. Menziesii (Syns. *N. atomaria*, *N. auriculaeflora*, *N. crambeoides*, and *N. modesta*).—There are many varieties of this, for example, *alba* is white, with a black centre ; *coelestis* is blue and white ; *discoidalis* is purple and white ; and *oculata* is blue and black. All flower freely from July onwards, and average 9–12 ins. high.

NEOGAYA.—Now included in the genus *LIGUSTICUM*.

NEOTINIA.—Now included in the genus HABENARIA.

NEOTIOPTERIS.—Now included in the genus ASPLENIUM, for which see *FERNS AND FERN GARDENING*.

NEPETA.—See *CATMINT*.

NEPHRODIUM.—For the best species and varieties see *FERNS AND FERN GARDENING*.

NEPHROLEPIS.—For the best species and varieties see *FERNS AND FERN GARDENING*.

NERINES.—See *GUERNSEY LILIES*.

NERTERA (Nat. Ord. Rubiaceæ).

Nertera depressa (Syn. *N. repens*), popularly known as CORAL-BERRIED DUCKWEED, is frequently offered in nurserymen's catalogues as a desirable subject for edging the border or for the rock garden, with the information that it thrives in sandy loam and leaf-soil. There are, however, many better things. True, its red berries are quite attractive, but both the flowers (which are greenish) and the plants themselves are insignificant, as their height averages only 1–2 ins., and they are

thus best excluded where space is precious in favour of choice subjects.

N. depressa is too tender for northern gardens.

NETTING.—See *GARDEN NETTING.*

NETTLE.—See RED DEAD NETTLE and STINGING NETTLE in *WEEDS.*

NETTLE LEAF BELLFLOWER (*Campanula Trachelium*). — See *CAMPANULA.*

NETTLE TREE.—A name applied to the genus CELTIS. See *TREES.*

NEUBECKIA.—Now included in the genus *IRIS.*

NEW ENGLAND STARWORT (*Aster Novae Angliae*).—See *ASTER.*

NEW HOLLAND VIOLET (*Viola hederacea*).—See *VIOLA SPECIES.*

NEW VARIETIES OF PLANTS, 1914–1919. Notes on the best of these are added at the end of the chief Flower, Fruit, and Vegetable articles.

NEW YORK STARWORT (*Aster Novi Belgii*).—See *ASTER.*

NEW ZEALAND BURR. — See *ACAENA.*

NEW ZEALAND FLAX.—See *PHORMIUM.*

NEW ZEALAND SPINACH.—See *SPINACH: NEW ZEALAND,* and *TETRAGONIA.*

NEWCASTLE THORN (*Crataegus Crus-galli*).—See *TREES.*

NEWSPAPER.

This is most valuable to the gardener after the news has been read, and should not be destroyed wholesale as is so often the case. In greenhouses which are only slightly heated, hundreds of plants may be saved from being frosted if a thick layer of newspaper is put over them the night before, and in cold frames this is even more valuable. In the latter case flower sticks should be put in at intervals for the paper to rest upon, and this should be as near the glass as possible. The newspaper can be used over and over again if it is spread out in the sun or in some warm place indoors to dry after use.

NICKAU PALM (*Rhopalostyle Sapida*). See *PALMS.*

NICOTIANA.— See *ANNUALS, HALF-HARDY: LIST OF,* and *TOBACCO PLANT.*

NICOTINE AND SOAP WASH.—See *INSECT PESTS: GENERAL METHODS OF DESTRUCTION.*

NIGELLA.—See *LOVE-IN-A-MIST.*

NIGHT-SCENTED STOCK (*Hesperis.* Nat. Ord. Cruciferæ).—There are twenty annual, biennial, and perennial species of Hesperis, many of them sweet-scented. The plant under notice (*H. tristis*) is the best biennial sort, and may be easily raised by sowing seeds in the open garden in April, May, or June, and transplanting to the border in autumn. It makes a first-class wall plant; its pretty cream, or at times brownish-red or purple flowers, being given from April to August on plants 1–2 ft. high. Another good biennial sort is *Hesperis grandiflora,* which bears white and purple flowers from July onwards on plants 3–4 ft. high, and a third sort sometimes grown is *H. laciniata,* which bears pretty purple flowers in May on plants 2½ ft. high. The ANNUAL SPECIES are hardly worth describing, but the PERENNIAL SPECIES will be found in our article on *ROCKET.*—J. F.

See also *STOCKS: ANNUAL SPECIES.*

NIGHT SOIL.

It always seems to us one of the biggest national sins that Night Soil is not taken more care of than it is. Under the present arrangements, outside water-closets run into ashpits, into which kitchen ashes, by no means free from cinders, are thrown daily by the resident of that house. In due course the ashpit is "full"—in other

words, it is up to the level of the gap through which ashes are thrown, and it becomes necessary to have it emptied. A cart calls at midnight and empties this pit, the material of which is fully charged with plant-food, and very often the carter sells the material to some gardener or other for use on his land. This night soil is very often the undoing of the gardener; instead of being good stuff, it is often terrible material, on account of the many sharp fragments of cinder ashes it contains. So the gardener should avoid it, for it will produce scores of scabs in potatoes, parsnips, beet, and other roots, both of a tuberous- and tap-rooted nature.

The proper way of making night soil is to have the closet entirely separated from the ashpit. The closet if outside should on no account be a water-closet, but an earth-closet of the good old-fashioned type. The urinal should be separate, and should run to a cesspool with the drainings from the house. The contents of the pan, which ought, of course, for sanitary reasons to be emptied daily, are very rich as regards food and humus, and provided the earth used is earth in the strictest sense of the word, and entirely distinct from ground grit or ashes, then the material will be of high value as manure. The most convenient way is to form a long, low stack of it in some out-of-the-way part of the garden free from trees, and cover the heap with a good thick layer of earth. After decomposing for a few months, this grand material can be freely used for the vegetable garden, and also in the fruit garden. Four to six cwts. can be used per square rod if put on in the autumn. Any ordinary disinfectant used in the closet will not impair the value of the manure, but may indeed improve it. Probably it is best to avoid applying lime when stacking the night soil, as lime is apt to vaporise the ammonia it contains.—E.

NIGHTSHADE.—See *SOLANUM*, and under BLACK NIGHTSHADE and ENCHANTER'S NIGHTSHADE in *WEEDS*.

NIGRITELLA.—Now included in the genus HABENARIA.

NIKKO SILVER FIR (*Abies homolepis*).—See *TREES*.

NOCTUIDS.—See SURFACE LARVÆ in *INSECT PESTS.*

NOISETTE ROSE (*Rose noisettiana*).—See *ROSE SPECIES.* For the best varieties see *ROSE CLASSES.*

NOMOCHARIS (Nat. Ord. Liliaceæ).—This is a new genus, a native of China, partaking of the characters of Calochortus, Fritillary, and the Lily. *N. pardanthina* is the only species so far introduced. The flowers, which appear in June, are widely bell-shaped, drooping, and in colour rose, with crimson spots at the base ; the outer surface is dark. The leaves are scattered or in whorls, and the height is 1 ft. It is hardy, and will thrive in any well-drained soil, and calls for no special cultural treatment. Propagation is best effected by seeds. The bulbs are used for food by the Chinese.

NON-METALLIC ELEMENTS. — See under OTHER ELEMENTS in *CHEMISTRY FOR GARDENERS.*

NORTH BORDERS : SOME PLANTS FOR.—Many more plants will thrive satisfactorily in a north border than is usually known, though naturally such plants are later in growth and flowering than when placed in more congenial positions. The nature of the background, too, which gives the northerly aspect, has much to do with their development and success. For example, north borders backed by a brick or stone wall will make plants later than if the background were a wood-fence, a shrubbery, or a hedge ; and this because, through the latter, some warm air and light will be sure to penetrate to the plants, whereas none is possible through a rigid wall.

But the chief requisite for successful cultivation of plants on a north site is, I am convinced, the nature of the soil. If this is reasonably light, and the border properly drained, artificially, if not naturally, then success can be assured with a fairly large choice of subjects. On the other hand, if the soil is heavy, and sticky in texture, and the position badly drained, it is practically useless to expect those healthy results which gladden the hearts of all really true gardeners. Indeed, money, time, and plants are almost wasted if the rooting medium for plants in any position is unfavourable, but especially is this true when dealing with plants destined to fill northerly situations where a ray of sunshine rarely, if ever, comes. At the same time, it should be remembered that a north border rightly prepared can become the means of prolonging the flowering season of many of our hardy plants.

It may be helpful to beginners to divide the examples now given into two groups—spring flowering and summer flowering.

Spring-Flowering Plants. — Bluebells, Columbines, Crocuses, Fritillaries, Hepaticas, Lily of the Valley, Narcissus—under which name is included the commoner Daffodils—Primulas—especially those of which japonica is representative — Primroses, Saxifrages—the London Pride

(*Saxifraga umbrosa*) being worthy of special mention—and Snowdrops.

Summer - Flowering Plants. — Asters (Michaelmas), *Campanula persicifolia, Eupatorium hirsutum,* Helianthus, Iris (Spanish, and the yellow water Iris), Lupines, Mallows, Musk, *Myosotis palustris,* Spiraeas. All these, once they are established, may be relied upon to succeed, though naturally the date of their flowering will be later than if they were growing in warmer places. The lists are not exhaustive, but they are given as a guide to those whose lot it has not been to glean largely in the field of experience.

In addition to the above there are a few plants for usage which may be termed temporary subjects—plants prepared in pots, usually, to fill up gaps and produce a little extra brightness. A few of such are—among Annuals—Asperula, Candytuft, Viscaria; Ageratums and Calceolarias, these latter enjoying the cool and shade perfectly; Canterbury Bells, whose flowering period is greatly prolonged by the northern aspect, and dwarf blue Lobelias. Of those plants just mentioned, the Lobelia in particular, it is safe to say, is known and thought of as a sun-loving summer bedding plant, yet the writer has had it flower splendidly on a north border, some parts of which were quite untouched by sun.

Hardy Ferns. — Another feature of true permanent worth for north borders is the use of Hardy Ferns. Most natural and pleasing results follow the planting of bulbs between a few Ferns grouped together. It hardly matters which kind of spring blooming bulb one employs for associating with Ferns. The arrangement is bound to satisfy; and by the time the foliage of the bulbs become unsightly, the Fern fronds have developed into a natural screen of such. Hardy Ferns, too, can be used in conjunction with the flowering plants, both being irregularly grouped in lots according to the space at disposal. Deciduous and Evergreen species are available for this purpose.

Climbers.—These, too, have a place in the north border, though the selection is much more restricted when compared with those serviceable for other aspects. Where the background is of shrubs, or a hedge, no climbers are really necessary, but some can be used if wished, and trained to single posts, tripods, or a framework. Should a wall or wooden fence be in existence, the desire for masking will be felt. This can be done with the hardiest climbing Berberises, Cotoneasters, *Crataegus Pyracantha,* Escallonias, *Garrya elliptica,* Ivies, Jasmines, Perennial (Everlasting) Pea, Roses, Virginian Creeper, and, where not too exposed to winds, the hardier Camellias can be tried. Some of these, though not strictly climbers, can be successfully so used when trained. Where it is desired to combine utility—food-value—with beauty, nothing better can be employed than Crab Apples, Morello Cherries, Gooseberries, and Red Currants. Both Cherry and Crab in blossom are a truly grand sight.—C. T.

NORTHERN FOX GRAPE, or FOX GRAPE (*Vitis Labrusca*). — See *CLIMBING AND TRAILING PLANTS.*

NOTICE TO QUIT.—See *GARDENING LAW.*

NOTIFIABLE DISEASES AND PESTS. — It is remarkable that so few gardeners know that certain diseases and pests which attack their crops are notifiable to the Board of Agriculture at Whitehall Place, London, S.W.1, under penalty of a fine of £10. It is unnecessary to print here the order governing such notification, as copies can be had from the Board's Office, but every gardener should acquaint himself with its provisions if he wishes to steer clear of censure or fines. The following, however, are the names of the notifiable diseases and pests :—

Diseases. — American Gooseberry Mildew, American Pear Blight, Black Knot, Black Scab, Cucumber Canker, Melon Canker, Tomato Leaf Spot, and Wart Disease.

Pests.—Brown Tail Moth, Cherry Fly, Colorado Beetle, Gypsy Moth, Large Larch Sawfly, Mediterranean Fruit Fly, Narcissus Fly, Nun Moth, Potato Moth, San José Scale, and Vine Louse.

The majority of these are described in our articles on *DISEASES OF PLANTS*, *INSECT PESTS*, *POTATO DISEASES*, and *TOMATO DISEASES*. One or two are omitted as they are practically non-existent in England, but should an unfamiliar disease or pest be discovered on any plant a sample should at once be sent to a qualified mycologist or entomologist for examination and report.

[It should be noted that Schedules dealt with under the Destructive Insects and Pests Acts or Orders vary from time to time. Gardeners can, however, always obtain the latest particulars with regard to these orders from the Board's Office. All alterations are, of course, widely advertised.—EDITOR.]

NOTIFIABLE PESTS.—See *NOTIFIABLE DISEASES AND PESTS.*

NOTOBASIS.—Now included in the genus *CNICUS.*

NOTOSPARTIUM.—For best species see *SHRUBS.*

NUPHAR.—See *YELLOW WATER LILY.*

NURSERY AND MARKET GARDENS. See *WOMEN GARDENERS.*

NUT, COMMON.—See under COBNUT, FILBERT, AND HAZEL in *NUT CULTURE.*

NUT CULTURE.

Considering the importance of Nuts as food, the cultivation of the various Nut-producing trees has never received, in this country, the attention it deserves. In nutritive value Nuts take a high place, and in some parts of the world they form a staple article of diet. The Sweet, or Spanish Chestnut, for example, is consumed in great quantities in some parts of the Continent, there being several methods of preparing it for table, one of which is the well-known "polenta," a form of porridge. Until recent times, considerable quantities of all kinds of Nuts were annually imported into Great Britain. It must, of course, be admitted that some kinds, such as the Brazil Nut and the Cocoanut, are altogether unsuited to outdoor cultivation in our climate; while others, such as the Almond and the Spanish Chestnut, though hardy, are uncertain in cropping, unless given conditions favourable to the ripening of their fruits. But even the Cobnut and Filbert, varieties of *Corylus Avellana*, and indigenous to Britain, are in most gardens sadly neglected, rarely producing anything like the crops of which they are capable under good cultivation, while they likewise present a splendid field for experiment at the hands of the hybridist. The following are notes on some of

the most important Nut-producing trees :—

Almond, Sweet (*Prunus Amygdalus dulcis*).—The Almond is chiefly grown here as an ornamental tree, and there are numerous varieties. It is one of the first trees to flower early in the year, and in consequence the blossoms are cut off by frost and cold winds, so that it rarely bears fruit. But in a fairly sheltered situation the tree under notice will often ripen its fruits. It will grow in any good soil, well dug, and containing lime. The usual method of propagation is by grafting on the common Plum stock. It reaches a height of about 20 ft., and calls for no special treatment. The Bitter Almond (*P. Amygdalus amara*) fruits under similar conditions.

Barcelona Nut.—See below, under COBNUT, FILBERT, AND HAZEL.

Brazil Nut.—This is produced by *Bertholletia excelsa*, an evergreen tree which, in its native home, reaches a height of 100 ft. In this country it can only be grown in a greenhouse with a winter temperature of 55–60° F. The soil should be a mixture of peat and loam.

Butter Nut.—This is the fruit of *Caryocar nuciferum*, a tropical tree growing 100 ft. high, the culture of which in this country is not possible.

Chestnut.—The edible Chestnut is known as the SWEET or SPANISH CHESTNUT, and botanically as *Castanea sativa*. The HORSE CHESTNUT (*Æsculus Hippocastanum*) is totally unfit for human food, nor will the horse touch it. The Sweet Chestnut makes a very handsome tree, reaching to 50 ft. in height, and the timber is of considerable value. It likes a deep, but by no means heavy loam; but if Nut production be the object of its cultivation, its root run should be restricted by planting it where the soil is not more than 18–24 ins. deep, with a thick layer of stones or bricks at the bottom. This prevents the formation of tap-roots, and stimulates the growth of fibrous roots, which in their turn lead to a dwarf habit and earlier fruiting. The situation should be warm, and the trees should not be exposed to cold winds from the North. Beyond this, no special treatment is required, and little or no pruning is called for—indeed, pruning means no fruit, the Nuts being borne at the ends of the shoots. There are several varieties, of which *Devonshire*, *Downton*, and *Prolific* are most grown of British Chestnuts; of French, *Marron* and *Marron ordinaire* are esteemed, others being *Châtaigne Ancisse*, *Châtaigne Bois Jaune*, *Châtaigne Crosnière*, and *Châtaigne Vert de Limousin*, but these are not so suitable for the English climate. They are propagated by grafting on the common Chestnut.

Cobnut, Filbert, and Hazel.—These are all varieties of *Corylus Avellana* and *C. maxima*, to which also belong the BARCELONA NUT or SPANISH NUT. The term COB was formerly given to those Nuts with a short calyx or husk; while those with a long calyx were known as FILBERTS, supposed to be derived from "full beard," referring to the calyx; but nowadays, owing to intercrossing, this distinction of naming is not maintained. The HAZEL embraces all forms, including the COMMON NUT or WILD NUT. Almost any soil will suit these trees, but they especially revel in a fairly light loam. Whatever the nature of the soil, it should be deeply dug and well drained. Left to themselves they make dense bushes, throwing up numerous suckers from the base, and bearing little "fruit." With proper training they can be made very productive. The usual

method is that known as the Kentish or Maidstone system. This consists in growing the trees on short stems, up to 2 ft. in height, from which a head of six or eight main fruiting branches is formed. These branches are shortened back a third or one-half, and the centre of the bush is kept open, to assume a vase-like form. From the cut-back shoots others will spring, which in turn are shortened the following year, the leading shoots also being shortened. The Nuts will be borne on spurs on the laterals or side branches, and once the trees are formed the pruning will consist in cutting out those shoots that have fruited, and shortening the growths so that the trees are not more than 6 ft. or so in height. The fruit is borne on ripened shoots of the previous year's growth. All suckers that spring from the base or from the stem must be promptly cut out, also all dead wood and unnecessary twigs. The male and female blossoms are borne separately, the females being small, and scarlet or pink in colour; the male blossoms are long, soft catkins. These shed their pollen in early spring, and not till after this is done should pruning be attempted—if done too soon, the female blossoms will not be fertilised, and there will be no Nuts. Gathering should not be done till they are fully ripe and brown; they can then be stored in a dry place or in sand. The BARCELONA NUT is *Corylus maxima barcelonensis*. Of the numerous varieties of Cobnuts and Filberts, the following are among the most popular: *Cosford Cob, Kentish Cob, Duke of Edinburgh, Pearson's Prolific, Red-skinned Filbert, Webb's Prize Cob, and White-skinned Filbert.* Propagation is usually effected by layers, cuttings, and grafting.

Cocoanut.—The fruit of *Cocos nucifera*, an East Indian Palm, reaching 50 ft. in height, and suitable only for greenhouse culture in Britain. [It is also known by the name of COCONUT.—EDITOR.]

Hazel.—See COBNUT, FILBERT, AND HAZEL.

Hickory.—See WALNUT.

Nut, Common.—See COBNUT, FILBERT, AND HAZEL.

Pistachio Nut.—This is the fruit of *Pistacia vera*, which does best on a wall, or on a sheltered south aspect. Male and female blossoms are borne on separate trees, and, when planting, care should be taken that both sexes are represented. A rich loam, deeply worked, is best for this tree. The Nuts grow in clusters. It may be well to point out that this tree so seldom fruits in this country that, if Nuts are the object, it cannot be recommended for general culture. The Nuts require to be cooked to be palatable.

Sweet Almond.—See ALMOND, SWEET.

Walnut.—This, by many regarded as the King of Nuts, is the fruit of *Juglans regia*, a handsome tree, valuable also for its timber. It reaches a great height, and does not commence to bear freely until it attains a good age; but by special cultivation varieties have been produced of dwarfer habit, which fruit when much younger. It should have a good loamy soil, but does not need shelter, as it is quite hardy. There were at one time many varieties which are now rarely met with, such as *The Yorkshire, Highflyer, Duck Nut, Hâtif*, and *Thin-shelled; Fertilis* is a more modern, early-fruiting variety. The HICKORY NUT of America (*Carya sp.*) belongs to the same family, the Nuts being distinguished by their smooth shells, which are very hard, and mostly with a small kernel. It requires the same treatment as Juglans.

W. J. C.

NUT GRASS (*Cyperus rotundus*).—See *CYPERUS*.

NUT PINE (*Pinus sabiniana*).—See *TREES*.

NUT WEEVIL.—See *INSECT PESTS*.

NUTMEG.—A name applied to the genus TORREYA. See *TREES*.

NUTMEG GOURD.—See *ORNAMENTAL GOURDS*.

NUTMEG HICKORY (*Carya myristicaeformis*).—See *TREES*.

NUTTALLIA.—Now included in the genus CALLIRHOË. See also *SHRUBS*.

NYCTERINIA.—See *ANNUALS, HALF-HARDY : LIST OF*.

NYMPHAEA.—See *WATER LILIES*.

NYSSA.—For the best species see *TREES*.

O

OAK.—For best sorts see QUERCUS in *TREES*.

OAK FERN (*Polypodium Dryopteris*). See *FERNS AND FERN GARDENING*.

OAK MILDEW.—See *DISEASES OF PLANTS*.

OAK-TONGUE.—See EDIBLE FUNGI in *FUNGI: EDIBLE AND HARMFUL*.

OAT.—See *AVENA*.

OBLONG WOODSIA (*Woodsia ilvensis*). See *FERNS AND FERN GARDENING*.

OCIMUM (BASIL. Nat. Ord. Labiatæ).—This is a genus chiefly of tender exotic annuals and shrubs suitable for the hothouse. The most important species is *O. Basilicum*, popularly known as BASIL or SWEET BASIL, the culture of which is briefly outlined in our article on *POTHERBS*, which see.

ODONTARRHENA.—Now included in the genus *ALYSSUM*.

ODONTIODA, ODONTOCIDIUM, ODONTOGLOSSUM, and ODONTONIA.—See *ORCHIDS*.

ODONTOSORIA.—Now included in the genus DAVALLIA, for which see *FERNS AND FERN GARDENING*.

ŒNANTHE (WATER DROPWORT. Nat. Ord. Umbelliferæ).—This is a genus of weedy and poisonous plants of no garden value, but dangerous to have about. They are sometimes grown in the wild garden, but might well be dispensed with. *Œ. crocata* (Syn. *Œ. apiifolia*) is the well-known WATER HEMLOCK, the leaves of which omit a violently poisonous juice when crushed; *Œ. peucedanifolia* (Syns. *Œ. silaifolia* of some authorities, and *Œ. Smithii*) is the SULPHUR-WORT; *Œ. Phellandrium* is the HORSE-BANE; and *Œ. pimpinelloides* (Syn. *Œ. Lachenalii* of some authorities, not of Grueliy), is the MEADOW PARSLEY.

ŒNOTHERA.—This genus is treated under *EVENING PRIMROSE* and *GODETIA*.

OHIO BUCKEYE (*Æsculus glabra*). — See *TREES*.

OHIO SQUASH.—See *ORNAMENTAL GOURDS*.

OIL OF VITRIOL.— The same as SULPHURIC ACID. See *ACIDS: THEIR USES IN HORTICULTURE*. It is also the same as VITRIOL. See *WEED KILLERS*.

OILEUS.—Now included in genus NARCISSUS. See *NARCISSUS SPECIES*.

OLD BLACK SOILS: IMPROVING.—See *SOIL IMPROVEMENT*.

OLD-FASHIONED FLOWERS.

It is of interest to consider what were the flowers of gardens in the days of our great-grandmothers, or of about a hundred years ago, and to think how charming those gardens must have been, although many of the plants that we now think indispensable were then unknown. From the middle to the end of the eighteenth century there had been in operation that great change in the treatment of pleasure-grounds that involved the inclusion of much larger spaces. In some ways it was a wholesome innovation, for it gave a wider outlook in all senses; but, as with all matters of prevailing fashion, it had regrettable consequences. For there were then existing all over the country the small enclosed gardens of Manor Houses and those belonging to many a modest dwelling of fairly well-to-do people; gardens that had remained unchanged since Jacobean and even Tudor times, but that must now be swept away in obedience to the new fashion of landscape gardening. But a few people were faithful to the old gardens, and to the old garden flowers also, and to

this day these remain and retain a special degree of loving appreciation such as we do not extend to the many newcomers, however gorgeous they may be and however well fitted to take their places in our modern pleasure-grounds.

There were then, as now, special fanciers of one kind of flower, so that by long-continued care in breeding or selection better varieties had been obtained; but these examples of what we should call florists' flowers were then confined to very few sorts. If one mentions Auriculas, Carnations, laced Polyanthus, and Tulips, it was about all. Pansies were the next to be taken up. Then, about the middle of the nineteenth century, came the use of tender plants for summer bedding. It was a cruel blow to the old-fashioned flowers, for in many gardens they were either abolished or so little considered that they ceased to count. Happily nothing was absolutely lost, and we have now made up, by restoring them to use, for the neglect of those thirty or forty years when the bedding system was almost exclusively in vogue.

We ask ourselves, Is it the force of old association, or is it that our ancestors had the sense to get hold of the most delightful flowers? We know not; we only feel that what we know as old-fashioned flowers have a kind of charm that makes them more lovable than all the fair plants of more recent introduction. We cannot fail to realise this when we think of a few, such as Honeysuckle, Jasmine, and Moss Rose.

To pass briefly in review, season by season, some of the chief of the old-fashioned flowers—the earliest expected were Snowdrops, then Crocuses, white, purple, and yellow, in lines or patches in flower borders; no one had then thought of the better way we have now lately learnt of having them in grass, nor were they in such numbers of varieties as now. Daffodils also were but few, the one most general in gardens being the old double yellow *Narcissus Telamonius*. Here and there one might find an early form of *N. incomparabilis*, and perhaps a few patches of *N. nanus* and the pretty little *N. minor*. Others were known, such as the good double Queen Anne's Daffodil and the white *N. moschatus*; but they were in special collections only, not in general use. There were the sweet-scented Jonquils, both the true rush-leaved kind and the commoner Campernelle, also the single and double *N. Poeticus*. During January and February there were three good flowering shrubs—Laurustinus, Yellow Jasmine, and, almost more generally than now, the sweet-scented *Daphne Mezereum*, a plant beloved of cottagers, and never seen to greater advantage than in one of those little garden strips between road and cottage that do so much to give beauty and interest to our English roadsides.

In March there was that charming plant Blue-eyed Mary (*Omphalodes verna*), of creeping habit, with leaves of vivid green and pure blue flowers much like Forget-me-not—one of the best of spring flowers and much, too much neglected. Then came double Daisies, red and white, of moderate size, favourite plants for edging, and better in proportion than the modern ones, in which size is greatly overdone. Violets were still of small size; the usual garden kind, known as the Russian Violet, was only a shade larger, if larger at all, than the deliciously scented purple, white and ruddy forms of the wild plant. But there was a double purple Violet, fairly hardy—

that was more fully double than the kinds now grown in frames, the bloom being almost globular—that has now become rare in cultivation. Rosemary, one of the oldest and most favoured of garden shrubs, is in bloom very early in the year; it was in every garden. And there were always two bulbous plants blooming in March or earliest April —the Common Dog's Tooth Violet (*Erythronium*), with its dull pink flowers and beautifully spotted and marbled leaves, and the Purple Fumewort (*Corydalis*), also of a "sad" pinkish colouring of the same class.

Primroses were always favourites, though the singles were in fewer kinds and colourings than now. But the pretty double Primroses, white, yellow, and lilac, were then more grown, and much attention was paid to the laced Polyanthus. Wallflowers were always welcomed, though for a long time there were none but the brown. But there was a capital plant, now only lingering in cultivation and but rarely seen, that was formerly in almost every garden—the perennial double yellow Wallflower. It is a bushy, half-woody plant that goes on for years; just a little tender, and likes to have its back against a warm wall. [This plant is delightful.—EDITOR.]

The end of April brings the Poet's Narcissus, and its still better and later blooming double kind; a flower unsurpassed for beauty and value by any of the more modern Daffodils. With it comes the sweet-scented leafing of Sweetbrier. Crown Anemones will have finished their bloom, but from the end of April to the middle of May Tulips are in full beauty. The kinds are those that have of late years been searched out and restored to favour under the general name of Cottage Tulips, besides the Breeders and Byblœmens of the Dutch, and a number of the flaked and feathered named sorts of the Tulip florists. May also brings Columbines; they were of the short-spurred kinds only, in the purple, white, and dull red colourings in which we still have them. Lily of the Valley and Solomon's Seal were in every garden, though now we plant them by preference in woody places. Pansies were already the subject of special cultivation, though the pretty kinds we now have with frilled edges and rich red colouring were not yet known. Then in May also came the Sweet Rocket, both white and purple. The excellent and still more sweetly scented double Rockets, flowering later, were also old favourites; they are still to be had, though they are no longer in general cultivation. The wealth of Flag Irises that we now have were not available three generations ago; the old blue Flag alone was in every garden, and the grey-white *Iris florentina* was not uncommon. Thrift was prized as an edging plant, also London Pride and the good old white Pink, and for this use we have not found anything better among flowering plants. The white Pink is in fact a better thing than the larger modern kinds that in so many gardens have taken the place of the old favourite, one of whose many merits is its close habit and good silvery foliage in winter. May also brought the grand old double Paeonies, varieties of *P. officinalis*, in three colourings, crimson, deep rose, and pinkish-white; these remain much as they were in the old days. May was always the special month for flowering shrubs, and white Broom, Deutzia, Guelder-rose, Laburnum, Lilac, Ribes, and Syringa were in every garden. Lilacs that have of late years been so greatly improved by the work of French nurserymen

were then of two kinds only, namely, white, and the soft light purple that has made "lilac" a colour word. The Honeysuckle that we know as *Early Dutch* was one of the old favourites, and was much used for covering arbours. Another old arbour plant was the Tea-tree or Box Thorn (*Lycium*); still the best thing for forming a neat living shelter. One of the later of the flowering bulbs, the Feathered Hyacinth (*Muscari monstrosum*), was a favoured plant. The aromatic Southernwood (*Artemisia Abrotanum*), though without flower in our climate, should not be forgotten, for it was much prized in cottage gardens, when it was commonly the custom for a spray of it to accompany the prayer-book to church, both being wrapped round in a clean handkerchief.

June brought Day Lilies and the great Orange Lilies, perennial Lupines, Pinks, and Red Valerian (*Centranthus*), with all the old Roses. The Roses, in fact, began in May with the bloom of the Scotch Briers, white, pink, and red, and the clear pink of the early bloom of China Rose. But in June came the Damask Roses, red, and red and white, and the old garden rose nearly related to Damask named *Reine Blanche*, creamy-white, with a narrow edging of red that makes the buds nearly all red. Cabbage Roses too and their crested varieties the Moss Roses; also a number of sorts of the old *Rosa gallica*, nearly all now discarded. There were also a number of Climbing Roses, the Musk Rose and a number of those we knew as Ayrshires, hybrids of *Rosa sempervirens*, many of which are still unbeaten in spite of the large numbers of modern kinds. There were also the Boursaults, Roses without prickles, derived from *Rosa alpina*. One of these, the *Blush Boursault*, has a purity of colouring, of milk-white deepened to a rosy centre, such as no other Rose can show.

With June and July came in the taller of the border Campanulas, *C. latifolia* and *C. persicifolia*, with Canterbury Bells and Sweet Williams, also the rosy Everlasting Pea, the sweet late Dutch Honeysuckle, Monkshoods, both purple and purple and white, several kinds of Stocks, and, above all, Carnations. Of the last, the one most generally grown was the *Old Crimson Clove*, of hardy nature and sweetest scent. There was an old kind something between a Pink and a Carnation called *Anna Boleyn*, in colour soft pink with darker centre, and very sweet. This appears to be lost, as recent inquiries for it have been answered by an assortment of flowers bearing the same name, but in no way equal to the original. Then there was the old kind called *Painted Lady*, with the back of the petals almost scarlet, and so short and stocky in habit that it was difficult to layer. This still exists, but has become rare.

The White Lily (*L. candidum*) was one of the glories of the July garden, as it still remains, for, notwithstanding the introduction of a number of other splendid species, the White Lily, in its stately beauty and purity, always holds its own. The other Lilies of the old gardens were the purple Martagon, two scarlet kinds, *L. chalcedonicum* and *L. pomponium*, the orange *L. croceum*, already mentioned, Tiger Lilies, and the earlier *L. pyrenaicum*, not of any great beauty and with a rank, unpleasant smell.

Lavender was always one of the joys of August, precious for drying and as an ingredient of potpourri, and the same season brought the ever-welcome white Jasmine, a well-

deserved favourite of all time. Then came Phloxes, few in number and very poor in quality compared with those of the present day; thin and narrow petalled and of straggling habit. There were also a few Snapdragons of what we should now consider wretched quality, some Dahlias of the old show kinds, and China Asters.

The September show of bloom was not of much account save for the continued flowering of the Dahlias, but there were also French and African Marigolds. Of other annuals there were certain old favourites: Sweet Peas in four sorts only, viz. white, pink and white, purple (light and dark), and the finely splashed mixture that may be called roan. But they were deliciously sweet, a good quality that has been in large measure lost with the improvement of the bloom and the increase of the number of the varieties. These annuals were also commonly grown: the always charming *Collinsia bicolor*, Convolvulus, both tall and dwarf, Cornflowers, blue and purple, Love-in-a-Mist, Mignonette, Nasturtium, and the pretty blue Nemophila, Night-scented Stock, Sweet Sultan, and Virginian Stock. This brief account is by no means an exhaustive description of the resources of the old gardens, but it gives a fair idea of the flowers commonly in use about a hundred years ago.—G. J.

OLIVES.

Although the genus Olea comprises about thirty species of evergreen trees or shrubs, there is only one which is of general cultivation in England, namely, the COMMON OLIVE, *Olea europaea.* It is usually treated as a greenhouse plant; it will, however, thrive and grow freely out of doors in the warmer parts of Great Britain, such as the south-west of England and parts of Ireland provide. Around London it is quite hardy when planted against a wall, with a south aspect.

Culture.—Olives are among the easiest of plants to cultivate, but whether grown in pots or planted out it is essential they should have a well-drained, loamy soil. They must never be subjected to a very high degree of artificial heat, a temperature of 45° F. in winter being sufficient to keep them in a healthy condition. Propagation may be effected in the spring by means of seeds and cuttings, or by grafting; the latter method is largely practised in countries where they are cultivated extensively for their fruit, but it is only by grafting the special varieties on the wild Olive stock that they are maintained.

In order to secure evenly-balanced, well-shaped trees, it is necessary to prune them carefully. This should be performed in early spring, when the longest branches may be shortened back to within two or three buds of the former year's wood.

The Olive forms a low-branching, evergreen tree, 20–30 ft. high. Its leaves are dark green above and silvery beneath. The flowers are produced in small axillary panicles from wood of the previous year's growth, and appear in June and July. The fruit consists of an oily flesh and a hard kernel, at first of a yellowish-green colour, but turning black when ripe.

From the earliest stages Olives have been cultivated in their native countries Syria and Greece; for the oil which is obtained by pressure from the pulp of the fruit. The quality of the oil differs according to the variety, to the country of growth, also with the care in preparation. As a source of food, and in the cooking of other articles, it is one of the most valuable of all oils; it is also of great use in many industrial processes, being extensively used in the tinning of sardines. In this country its principal use is in the preparation of salads, etc. In Italy and Greece the fresh fruits are used for dessert, whilst unripe Olives appear as a pickle, and they are said to promote digestion. The best oil for the table is from Tuscany, next to it come the Florence and Lucca oils, while the Spanish oil is generally of an inferior quality. Olive Oil is used in medicine, for its nutritious and laxative properties, it is also largely employed in the preparation of ointments. Branches of the Olive have for ages past been regarded as emblems of peace and plenty.—T. W. T.

OMPHALODES (Navelwort, etc. Nat. Ord. Boraginaceæ).—All who know and value the beautiful spring flowering *Omphalodes verna* will appreciate its annual relative *O. linifolia*, which is a dainty little plant of easy growth, succeeding in a moist and shady position. Once sown in the spring or early autumn it seeds itself so freely that a succession of plants is easily secured. The white flowers are freely produced in July. The height varies from 6 ins. to 12 ins.

Rock Garden Species.—These are all ow-growing tufted perennials not difficult to establish. Most will thrive in half-shady situations in rich deep soil. They are increased by division in the autumn or spring, also by seeds sown in gentle heat in March.

Omphalodes cornifolia (Syn. *O. cappadocica*).—This has tufts of grey-green leaves. Flowers dark blue, in loose panicles. Site, half-shade. Soil rich leafy. Flowering Period, May to June. Height, 1 ft.

O. Luciliae.—A sort with tufts of glaucous leaves. Flowers pale sky-blue. Site, half-shade. Soil gravelly loam. Flowering Period, June to September. Height, 6 ins.

O. verna (Creeping Forget-me-not).—A creeping plant, with deep green rugose foliage. Flowers rich blue, with white eye. Site, half-shade. Soil rich sandy loam. Flowering Period, April to June. Height, 4 ins. Its variety *alba* has pure white flowers.

ONCIDIODA and ONCIDIUM. — See *ORCHIDS*.

ONCOCYCLUS.—Now included in the genus *IRIS*.

ONION (*Allium Cepa*. Nat. Ord. Liliaceæ).—The dawn of the present century witnessed a "boom" in the cultivation of onions, and unlike other booms in the horticultural world, thanks to the usefulness of the crop, each succeeding year has witnessed a large addition to the ranks of Onionists, and today the desire to grow bulbs 18 ins. in circumference, weighing from 3 lb. to 4 lb., is not restricted to the

professional or trade grower, it being most noticeable that even the merest tyro in kitchen gardening endeavours to secure a good bed of these. Even though the cost of producing these extra large bulbs is very considerable, there is not the slightest doubt as to their being a truly paying crop.

Bulbs half the size of those mentioned above are perhaps the most useful, and, providing the soil and the season are favourable, such may usually be secured with little more trouble than that given to other less useful or important crops.

Site and Soil Preparation.—No matter whether large or medium-sized bulbs are required, the site for the bed should be an open and sunny one, quite away from overhanging trees or shrubs, as bulbs, unless raised in sunny situations, lack both in size and keeping qualities.

A deep root-run is essential, and if the intended bed can be prepared by thorough trenching early in the winter, manure being added on a more liberal scale than for most vegetables, so much the better for the crop, four to six good barrowloads to each square rod forming a liberal dressing. The manure should be well buried.

It should be remembered that, providing the bed is kept free from pests, it may be occupied by onions for an indefinite number of years, each year with better results following; this being so, none need mind the extra trouble and expense the proper preparation of the bed for the first crop involves.

If trenching is decided upon, endeavour to mix a liberal amount of manure with the three spits, enriching the surface with plenty of lime, soot, or wood ashes, and always leaving the surface in a rough state all the winter.

Sowing.—Providing the soil is in a good friable condition, an outdoor sowing may be made any time after the middle of February until as late as the first fortnight of April, but as early sowing usually means early ripening, the sooner the seed is set, the better the bulbs will be ripened in a bad season. A good firm seed-bed is of great importance, and if the soil is made firm previous to sowing, and raked down quite level before drawing the drills, the seed will germinate better, and growth be more even than if the making firm follows the sowing. The distance between the rows should be about 8–12 ins., and they should run north and south. Sow not more than an inch deep, and rake the bed down level with a wooden rake, treading on it as little as possible.

When the plants are well above the soil reduce to not less than 2 ins. apart; the surplus seedlings may either be transplanted or used as a salad. A few weeks later thin them again, leaving them 4 ins. apart, at which distance very serviceable bulbs may be expected.

If what are termed as "boilers" are wanted in quantity, instead of sowing in the open air, sow seed of one of the largest growing varieties in boxes containing a good depth of rich soil, taking care that each seed stands clear of its neighbour. If this is done, and the box stood in a light airy position in the greenhouse, very useful plants should be available for transplanting to open quarters about the middle of April. If these are allowed a foot between the rows, and 8 ins. between the plants, bulbs large enough for most culinary purposes are assured.

For Exhibition.—To grow extra large bulbs, a good strain of a big variety must be secured. To be

sure of getting this, buy seed only from the raisers, or firms having a reputation for straightforward dealing. Sow in well-drained boxes not less than 4 ins. deep, filled with rich but porous soil—a too close soil preventing free root action. A compost of equal parts good oak leaf-soil, turfy loam and well-decayed manure is that used by many of our leading growers; this should be passed through a half-inch sieve, afterwards adding about an eighth part of coarse silver sand.

Distribute the seed very evenly, and not less than an inch apart. If sown more thickly than this, the plants grow very weak from the start, or require transferring to other boxes before each have made sufficient roots to enable the transfer being made without serious check to growth. Should pricking out not be decided upon, do the sowing with extra care, and for a few days following keep the soil on the dry side and shade from bright sun. During the early stages of growth seedling onions need very careful watering; cold water must be avoided, also a continual soddened soil, as where this is not guarded against disastrous results often follow.

From the middle of March to April 15th the plants should be stood in a cold frame, quite near the glass, and have abundance of air night and day when conditions are favourable. From the middle to the end of April, the light may be removed entirely or the boxes stood in a sheltered position in the garden until May.

Transplanting into the open bed should be done as early in May as possible. In doing this more than ordinary care should be taken to preserve the roots from injury. Where the plants are growing in boxes, it will be an advantage if one side of these is removed entirely, allowing a trowel or strong label to be placed beneath the drainage and the whole mass gently lifted without unduly disturbing the plants. Others in pots or pans should be knocked out without breaking the ball of soil, and when dividing endeavour to leave as much of this on each plant as possible. Allow not less than 15 ins. between the rows (18 ins. would be even better), and about 12–14 ins. between the plants. Set with a trowel, seeing that the holes are large enough to prevent cramping, and make very firm. Avoid burying more of the stem than is necessary to keep the plant in an upright position, and give a good watering immediately. Frequent syringing overhead is advisable, not only during the first few days after planting, but throughout the whole period of growth.

A month after the plants have become well established, well blacken the soil with old soot, and from the time bulbing commences until the middle of August, a weekly application of Nitrate of Soda or Sulphate of Ammonia, at the rate of an ounce per square yard, should be given. Following the application of the above, failing rain, the bed should be well hoed and if possible receive a thorough watering. On light soils watering is absolutely necessary during the summer months, if large bulbs are to follow, care being taken to give this in sufficient quantity to reach the lowest roots.

Should the summer be dry, and watering not possible, mulch the bed not less than an inch deep with half-decayed manure as soon as the plants show signs of forming bulbs; this will conserve the moisture in the soil, and subsequent rains will wash down plant-food to feed the roots.

Harvest the crop in September, taking care to handle the bulbs of all sizes very carefully, and store under cool conditions, but away from frost. See article *Vegetables: Harvesting and Storing.*

Good Varieties: — *For General Crop.* — Bedfordshire Champion, Brown Globe, Improved Banbury, James' Long Keeping, Model, Nuneham Park, Reading, Rousham Park, Sutton's A1, Up-to-date, Walker's Exhibition.

For Large Bulbs. — Carter's Record, Cranston's Excelsior, Dickson and Robinson's Premier, Dobbie's Golden Globe, Exhibition, Sutton's A1, Sutton's Ailsa Craig, Sutton's Prizewinner, Webb's Masterpiece.

Pickling Onions.—These are very useful and may be grown in soils of any description with every prospect of success. Sow thickly early in March or April in rows 6 ins. apart, only removing plants where these are very crowded. The variety chiefly sown for this purpose is *Silver Skinned*, but *Carter's Model* is a great improvement on this. Any of those advised for general crop will give good results sown at the distance here mentioned.

Potato Onions (*Allium Cepa aggregatum*).—Although by no means a popular crop with many kitchen gardeners, cottagers and amateurs in some districts find these most interesting and profitable to grow. They have the advantage over ordinary onions of being less trouble to cultivate, and being ready to leave the ground in July, allow ample time for a crop of another kind to follow. The treatment advised in our article on *Shallots* will give equally satisfactory results if followed for these.

Tree Onions (*Allium Cepa proliferum*). — These find but limited favour in many quarters, yet if given good cultivation there is no reason why they should not be as profitable to the grower as are many better known vegetables, particularly in households where much value is placed upon pickles or chutney, the small bulbs being most suitable for this purpose. They may be expected to give good results from land of almost any description, but like all of this family, the richer the soil, the better the results are likely to be. A position in the full sun should always be found for them, and not less than a foot allowed between the rows. It is open to the grower to plant either bulbs borne on the stem, or from the root. Planting should be done in March, and as growth proceeds support must be provided for the stems or many may be broken. As soon as the bulbs are fully ripe, gather them with care and store in a dry room or shed.—F. R. C.

New Variety.

Autumn Triumph. — The bulbs are as large as a *Giant Rocca*, but unlike that variety keep good until April or May.

ONION DISEASES.

Of such importance to food growers, amateurs, allotment-holders, and professional gardeners alike are Onion Diseases that we think it well to treat them in this separate article rather than include them in the general article on *Diseases of Plants*. The three diseases described will form good subjects for future research, and those with a taste for pathology would be doing the country a service if they could discover a speedy cure which would obviate the necessity of a lengthy rotation. The onion is a crop of great food

value, and the diseases are a serious menace to its successful culture.—EDITOR.

Onion Mildew (*Peronospora Schleideni*).—This Mildew occurs wherever onions are cultivated, and causes damage to the foliage, which hinders the proper swelling of the bulbs. It usually appears in June as a white mould on the leaves, which soon assumes a purplish hue. If the weather is dull and damp, it spreads with great rapidity. More damage is done if mildew comes on early in the season than if it comes on when growth is finished.

REMEDIES.—(1) Dust the plants when wet with dew with black sulphur, or lime and sulphur (1 part lime to 2 parts sulphur), as soon as the disease is noticed, or spray with Burgundy or Bordeaux mixture. (2) Give at least a three-year rotation as the resting spores persist in the soil. (3) Cultivate well, as this assists the plant to withstand mildew. (4) Keep a special watch on autumn-sown onions as these often start the disease.

Onion Smut (*Urocystis cepulae*).—Onion Smut is a serious disease in America, though comparatively rare in this country. It occurs chiefly in spring and early summer and is characterised by the presence of black streaks in the leaves and on the young bulbs. These finally burst open and liberate masses of sooty black spores. The latter fall to the ground, and hence the disease is carried to the soil, where it persists for several years. Leeks are also attacked.

REMEDIES. — Diseased plants should be carefully removed and burned as soon as seen. The selection of a new site and strict attention to clean culture as advocated for Onion White Rot are all that can be recommended.

Onion White Rot or **Dry Rot** (*Sclerotium cepivorum*). — In this very destructive disease the onion bulbs are attacked at the base by a fungus which forms a copious white mycelium and kills the roots and lower part of the bulbs. Both old and young bulbs are attacked. The fungus later produces minute round black bodies termed *sclerotia*, which are found in plenty on the dead and dying bulbs. These are resting bodies and reproduce the disease. The fungus is difficult to eradicate as the sclerotia retain their vitality for four or five years, and no substance has been discovered which will kill them without injuring the soil.

REMEDIES. — Diseased onions should be lifted at once; sound parts may be used as food, diseased portions should be burned. Onions should not be grown on infected soil for at least five years, and great care should be taken that the new bed is not contaminated with soil or manure from the old bed. Lime dressings have not been found of any avail.—A. D. C.

ONION DRY ROT.—The same as ONION WHITE ROT. See *ONION DISEASES*.

ONION FLY or MAGGOT.—See *INSECT PESTS*.

ONION MILDEW and SMUT. — See *ONION DISEASES*.

ONION TRIBE.—See *KINDS OF CROPS*.

ONION WHITE ROT, or DRY ROT.—See *ONION DISEASES*.

ONISCIDÆ. — See WOODLICE in *INSECT PESTS*.

ONOCLEA.—For the best species and varieties, see *FERNS AND FERN GARDENING*.

ONONIS (REST HARROW. Nat. Ord. Leguminosæ).—This is a large genus containing many hardy and tender annual, biennial, and perennial species. It is unneces-

sary to describe any here save those which are hardy herbaceous perennials. Some of the dwarfer of these last may be effectively used in the rock garden. All require the ordinary culture usually bestowed on perennials and rock plants, and succeed in common garden soil. They may be propagated by summer sown seeds or root division in the spring, and are best planted about the middle of March. We recommend the following :—

Ononis arvensis.—This is the well-known REST HARROW of the fields—not a very desirable garden plant—which bears purple flowers from June to August, and grows about 12 ins. high.

O. campestris.—Syn. *O. spinosa*, which see.

O. fruticosa.—This is the most popular of all the species, with its pretty pink flowers in May and June on plants 1½–2½ ft. high.

O. Natrix.—The flowers of this desirable species are veined red on yellow ground-work. They are produced from June to August on plants 1½–3 ft. in height.

O. spinosa (Syn. *O. campestris*).—This, and its variety *alba*, bear purple-pink and white flowers respectively from July to August, and average 12 ins. in height.

See also *SHRUBS*.

ONOPORDON (COTTON THISTLE. Nat. Ord. Compositæ).—This is a large genus of weedy, hardy annuals and biennials, the increased culture of which is not to be recommended. The best known species is *O. Acanthium*, the SCOTCH THISTLE, a very troublesome weed in many districts where the soil is on the poor side.

ONOSMA (ALPINE COMFREY. Nat. Ord. Boraginaceæ).—This is a large genus of rock plants requiring a dry position in full sun, and thorough drainage is essential for their success. They are propagated by seeds sown in gentle heat in March, or by cuttings in July. We describe the three best species :—

Onosma albo-roseum.—This has hoary, white leaves on sub-shrubby stems. Flowers white, changing to rose, in racemes. Site sunny. Soil gritty loam. Flowering Period, June. Height, 4 ins.

O. Bourgaei.—This has hoary leaves in tufts. Flowers white and bell-shaped. Site sunny. Soil gritty and stony. Flowering Period, June. Height, 4 ins.

O. echioides (Syn. *O. tauricum*) (GOLDEN DROP).—This has deep-green foliage, and produces narrow leaves in tufts on sub-shrubby stems. Flowers bright yellow. Site sunny. Soil, deep gritty or rock crevice. Flowering Period, May to July. Height, 9 ins.

ONYCHIUM.—For the best species see *FERNS AND FERN GARDENING*.

OPADIA.—See PLUM RED GRUB in *INSECT PESTS*.

OPENINGS FOR WOMEN GARDENERS. — See *WOMEN GARDENERS*.

OPHIOPOGON (SNAKE'S-BEARD. Nat. Ord. Haemodoraceæ).—Three species of this, *O. intermedius*, *O. Jaburan fol. var.*, and *O. japonicus*, are useful house plants for the home or conservatory, thriving in light loam, to which some peat has been added, the second species having pretty, variegated leaves. All bear yellow flowers from June to August, and average 1–1½ ft. in height. Being half-hardy perennials botanically, they are best propagated by root division in the spring.

OPHIORRHIZA (Nat. Ord. Rubiaceæ).—This plant, of which the English name is SNAKE-ROOT, must not be confused with the hardy Snake-roots of *Liatris* and other genera. It requires greenhouse

treatment in light, peaty soil, when it will produce white flowers in August on plants 1 yd. high. It cannot be said to be a plant of much value, though in the olden times it found favour as a remedy for snakebites.

OPIUM POPPY (*Papaver somniferum*).—See *POPPIES: ANNUAL SPECIES*, and *MEDICINAL HERBS*.

OPOPONAX PLANT (*Opoponax*, Nat. Ord. Umbelliferæ).—Two forms of this plant are sometimes grown in herbaceous borders, or in the wild garden, as hardy herbaceous perennials. These, *O. Chironium* and *O. hispidum* (Syn. *O. orientale*), are both yellow-flowered, and bloom in June, averaging 4–5 ft. in height. They have no special requirements, neither have they any special points of commendation.

OPORANTHUS.—Now included in the genus *STERNBERGIA*.

OPUNTIA.—See *CACTI*.

ORACHE.— See COMMON ORACHE in *WEEDS*.

ORACHE: or Mountain Spinach (*Atriplex hortensis* and *A. h. rubra*. Nat. Ord. Chenopodiaceæ).—This is one of the many plants the leaves of which serve as a substitute for Spinach. It is but little grown by gardeners in this country, excepting as an ornamental plant in the herbaceous border. It usually thrives in districts where ordinary Spinach fails.

Culture.—If an early crop is desired a little seed may be sown in a number of small pots early in March, placing these in a warm greenhouse and reducing the seedlings to one in a single pot soon after germination. Plant out in the open some time in April or early May when there is little danger of frost. The first outdoor sowing should not be made before the end of March, further sowings following at intervals of a few weeks throughout the summer and early autumn.

Sow in drills from 18 ins. to 2 ft. apart, and quite early in growth reduce the seedlings to 15 ins. apart in the row.

On rich soil the plant grows very quickly, and if a fair crop is to be taken from each plant, the importance of constant soil stirring, together with the systematic gathering of the leaves, should not be minimised, for even when grown under the most favourable conditions, the plant quickly forms flower spikes, after which the quantity of leaves produced suitable for culinary purposes is very limited; in fact, wherever possible sufficient rows should always be coming on to allow those showing signs of running to seed to be destroyed as soon as flowers appear.

ORCHARD HOUSE: MANAGEMENT OF.—The most suitable structure for an orchard house is one with a span roof, about 20 ft. wide, 5 ft. in height to the eaves, 10–12 ft. to the ridge, with spacious running ventilators on either side top and bottom, and having a central bed 7 ft. wide, surrounded by walls 2 ft. high, with beds arranged on either side of the house each 3 ft. 6 ins. wide, with similar walls. These beds should be filled in with any material suitable

for plunging the pot trees in; or if the trees are to be planted out in the beds, put in the bottom 6–9 ins. of broken bricks, etc., for drainage,—on this lay turves grass-side downwards, and fill in with good chopped fibrous loam, with old mortar rubble, charcoal, and bonemeal mixed in with it, in which plant the trees. Growing the trees in pots is much to be preferred to planting them out, as they are more under control and can be removed after the fruit is gathered, into the open for the winter months and derive much benefit therefrom.

Housing the Pot Trees.—Obviously the trees must be brought in before the flower-buds burst; this generally has to be done quite early in March, as by then Apricots, Nectarines, Peaches, and Plums are getting advanced. Plunge the pots to the rims in the beds, making them level and firm; arrange each different variety in separate groups, placing the Cherries on the shady side of the house, and putting Peaches and Nectarines where they will get the most light.

Ventilation.— Considering the inmates are all hardy fruits revelling in full light and air, it would be unnatural to coddle them, and this must not be attempted. Maintain a circulation of air continuously night and day, but avoid opening the bottom ventilators, which will admit gusts of cold air, while biting north or east winds are blowing in the early spring. If ventilation is not thorough, mildew will soon attack the young and tender foliage.

Fertilising.—To ensure an even set, assist the dispersion of the pollen artificially. When the flowers are fully expanded, brush them lightly over with a rabbit's tail, or fine-hair brush, about midday on sunny days. The atmosphere surrounding the trees in flower must be kept dry.

Syringing.—To keep the trees healthy and free from insect pests, syringe them twice daily on all fine days, commencing to do so as soon as they have passed out of flower, continuing right up to the time signs of the fruit ripening are observed. Should green or black fly appear, spray the trees with Quassia Extract, or some other safe insecticide, immediately it is noted.

Stopping and Thinning.—As pot trees are usually grown in bush or pyramid form, fruiting spurs must be encouraged to develop; this is done by pinching back the young lateral growths to about three joints while quite young, repeating the operation later when other growths are produced, allowing the leading shoots on the main branches to go unrestricted. Thinning the fruits must be done gradually, leaving the final thinning of all stone-fruits until after the stoning period is over; Apples and Pears may, however, be thinned directly the young fruits are seen to be swelling freely. Overcropping leads to exhausted trees and under-sized fruits.

Watering and Feeding. — These are the most important details connected with the orchard house. Trees must never lack moisture at the roots at any time. Early in the season they do not require much water, but need a lot more as the season advances. They will want watering four and five times a day during the summer. Feeding should be done regularly and systematically, commencing at first while the fruits are quite small with weak soot water, or liquid manure, at each alternate watering; later, supplement this once a week with a surface dressing of artificial manure, washing it in with clear water, gradually increasing the quantity as time goes on.

The placing of zinc collars around the top of the pots enables top-

dressings of chopped loam, intermixed with bonemeal, soot, and artificial manure occasionally to be applied.

The Ripening Period.—This extends over several months, commencing with early Cherries, finishing with late Plums and Pears. With a view to enhancing both colour and flavour of ripening fruits, expose them to all the light possible at this period. Apples and Pears must be tied on with raffia to secure them from falling. Wasps should be excluded by stretching wasp netting over the ventilators. Directly the trees are cleared of their crop move them outside, shading them at first from full sunlight to prevent the foliage scorching, but directly they become inured, sink them in the plunging ground, giving full attention to watering still.

Re-potting.—Directly the foliage changes colour in the autumn the trees should all be re-potted. In doing this, turn them out of their pots, and remove every bit of the old soil it is possible to work away from their roots. It will then be found that most trees will go back easily into the same size pots ; occasionally an extra vigorous tree will require a larger size, but be sure never to overpot, the secret of success being to have the pots well filled with roots. A compost consisting of good fibrous loam, old mortar rubble, charcoal, and bonemeal will be found suitable. Take care while potting to get the soil well home ; work it in by degrees, forcing it down with a thin rammer, and make it very firm. After potting return the trees to the plunging ground, and water them in.

Pruning. — Shorten back any young wood, removing all except two or three fruiting buds on the spurs and the extension shoots to two thirds of their length, as soon as the leaves have fallen.

VARIETIES TO GROW.

APPLES.—Suitable varieties for the Orchard House are : *Beauty of Bath, Charles Ross, Cox's Orange Pippin, James Grieve, King of the Pippins, Peasgood's Nonsuch, Ribston Pippin, Rival, Wealthy, Worcester Pearmain.*

APRICOTS. — *New Large Early, Moorpark, Oullin's Early.*

CHERRIES.—*Early Lyons, Early Rivers, Elton, Emperor Francis, Frogmore, Governor Wood, Mayduke.*

FIGS. — *Brown Turkey, Negro Largo, White Ischia.*

NECTARINES. — *Dryden, Early Rivers, Elruge, Humboldt, Lord Napier, Pineapple.*

PEACHES. — *Bellegarde, Crimson Galande, Duchess of Cornwall, Duke of York, Peregrine, Sea Eagle, Stirling Castle.*

PEARS.—*Clapp's Favourite, Conference, Doyenné du Comice, Le Lectier, Marguerite Marrillat, Marie Louise, Triomphe de Vienne.*

PLUMS.—*Coe's Golden Drop, Coe's Violet, Jefferson, Kirke's Belle de Louvain, Oullin's Golden Gage, Pond's Seedling, Primate, Reine Claude de Bavay.*—T. B. F.

ORCHARD TREES : ARRANGEMENT OF.— See *ORCHARDS : MAKING AND MANAGEMENT OF.*

ORCHARDS : ASPECT FOR. — See *ORCHARDS : MAKING AND MANAGEMENT OF.*

ORCHARDS : DRAINAGE FOR.— See *ORCHARDS : MAKING AND MANAGEMENT OF.*

ORCHARDS : MAKING AND MANAGEMENT OF.—After many years' practical experience of hardy fruit culture, and the opportunities afforded of examining the methods of other growers, the writer's conclusion is that there must be a radical change in the cultivation and management of Orchards, if they are to be the true success they might be. More attention should

be paid to details, and with a system of careful culture, a judicious selection of varieties to suit the soil, district, and markets there is a great future for the fruit growers of this country.

Aspect. — When selecting a site for an Orchard, the essential considerations are, aspect and soil. Some form of shelter is necessary from cutting winds or late spring frosts, and if no natural shelter exists, the difficulty may be overcome by planting on the windward side a belt of deciduous and evergreen trees. The ideal site is a gentle slope with a south aspect, well sheltered from other quarters, and high enough to miss the spring frosts, but not too elevated to be exposed to the north and east winds. The soil may not be so deep as in the lower or flat ground, but the quality, flavour, and colour of the fruit will be much finer, through being naturally more exposed to the sun and air.

Soil.—This is next in importance to shelter. Most soils by good treatment can be made to produce first-class fruit. Soils and subsoils vary considerably, and undoubtedly a good heavy loam of a greasy or retentive nature, resting on a clay subsoil, is the best.

It may be possible to obtain satisfactory results for a few years on shallow soils resting on a subsoil of gravel and rock, but not for long, since the roots in course of time penetrate the uncongenial lower stratum in search of food, and then the trees commence to canker and eventually die. Some of the finest *Cox's Orange Pippin* apples the writer ever saw were grown on ground with a subsoil of gravel, but the superstratum of excellent soil ran to a great depth. Very rarely does this happen, for usually subsoils of gravel or rock carry very shallow surface soils of inferior quality.

Drainage. — When the site is selected, drainage should be the first consideration, and whatever the condition of the soil may be, it is most essential that the land is efficiently drained. Stone drains are preferable to pipes in the writer's opinion. They should be set in rows 25 ft. apart, and buried at least 3 ft. in depth. Such drains serve the purpose admirably, and never get out of order. The land must be properly prepared—all new ground should be trenched 2 ft. deep, and the bottom of each trench turned over a spade's depth, and broken up, but not brought to the surface. If the work is commenced in the autumn or winter, it is advisable to delay planting until the following autumn, cropping the ground the following summer with potatoes, giving the seed plenty of space so that the soil can be freely cultivated. This will not only improve the crop of potatoes, but bring the soil into excellent condition for planting the trees in the autumn.

Planting. — The best time for planting all Orchard trees is from the end of October to the end of November. The soil being still warm at that period, the trees commence root action at once before the cold weather sets in. Presuming it is intended to lay the Orchard down in grass, standard trees should carry stems at least 5 ft. in length, so that the branches are beyond the reach of cattle.

Particular attention should be given to staking the trees and protecting the stems securely. As regards the distance at which the trees should stand from each other, it is very important that ample space be allowed for the admission of sun and air.

Standard Orchard trees should be

planted from 15 ft. to 25 ft. apart, the latter distance for preference, if the intervening spaces are cropped with vegetables for several years, which is advisable. To produce these vegetable crops, the soil has to be heavily manured and well cultivated, but the crops leave it in a splendid condition for the roots of the trees, when they have been established long enough to take advantage of it, namely, in about five years. The soil should then be levelled, rolled firm, and sown with grass seeds.

Arrangement of Trees.—Whether the trees are planted in squares or triangles, is a matter for the grower to decide, although planting in squares is strongly recommended, especially for Orchards on a large scale. This method facilitates the work of the horse cultivator, the carting of manure, and other work usually done by horse power. Standard trees should not be planted on a large scale, unless it is the intention eventually to sow the land with grass for grazing purposes. Bush trees are greatly preferable. They can be planted closer than standards; moreover, the work of spraying, pruning, and gathering the fruit is carried out with greater dispatch. Bush trees also come into bearing much sooner, and if they do not carry quite such heavy crops, this is more than repaid by the extra trees. Then the intervening spaces may be utilised for planting bush fruits such as Gooseberries, Raspberries, and Strawberries. The trees should not be allowed to carry much fruit for a few years, it being more essential to encourage growth and vigour by severely thinning the fruits.

Lime for Stone Fruits.—Calcareous loams are the best soils for all stone fruits, because they contain lime, and where this is deficient the soil should be corrected by a liberal dressing of old mortar rubble or slaked lime, in preference to any one of the widely advertised proprietary limes which are really of little use. This should be lightly forked into the ground previous to planting.

Mulching.—This matter is of some importance to the grower of Orchard fruit trees. The writer's opinion is that a light surface mulching of short stable litter should be placed round each tree after planting, to serve the dual purpose of protecting the roots from injury by frost in winter, and of retaining the moisture in dry summer weather. [We prefer not to mulch at planting time as the food in the manure cannot then be used.—EDITOR.] At a later period, when the trees are established and in fruiting condition, much heavier mulchings may be applied. Decayed vegetable refuse, soot, wood ashes, turf edgings, and half-rotted manure, all well incorporated some weeks in advance, form the best dressing for fruit trees. They not only encourage the young fibres to come to the surface, but impart colour to the fruit, and show a marked improvement in the foliage, especially after a heavy shower.

Weeding.—This also is important work for Orchard Gardeners. The surface soil should be kept scrupulously clean and free from all forms of wild plants. There is no better method of eradicating these harbours of insect pests than the frequent use of the hoe. It is impossible to exaggerate the importance of hoeing, to prevent rapid evaporation of moisture that takes place in hot weather.

Diseases.—The most destructive fungoid diseases with which the fruit grower has to contend are *Bladosporium dentriticum* on Pears, and Brown Rot (*Monilia fructigena*) on Apples. The latter attacks Apples,

Cherries, Peaches, Pears, and Plums, but it is more in evidence on Apples and Pears. The disease first attacks the foliage, but is usually noticed when it appears on the young fruit, in small brown spots, gradually increasing in size until the whole fruit is affected. The fungus spreads rapidly, and if neglected the young growths and fruit spurs become affected and covered with spores which mature during April and May. Carefully collect and burn all affected fruit, also the shoots when pruning. No cure is yet known, but preventive measures should be taken by spraying the trees when the leaf-buds are expanding with very weak Bordeaux Mixture, repeating the operation at intervals. [Other Diseases will be found in our articles on *Apple Diseases*, *Diseases of Plants*, etc.—Editor.]

Pests.—The Winter Moth, the Great Winter Moth, the March Moth, and the Codling Moth are the most destructive and troublesome of Orchard Insects. These are dealt with in the article on *Insect Pests*, which includes also Woolly Aphis (American Blight), Mussel Scale, Green and Black Aphis, Apple Blossom Weevil, and the Pear Midge. As soon as an attack is observed immediate steps must be taken to exterminate the pests, or great damage may be done.

Varieties.—The experienced grower is the best judge of varieties which suit any particular district, and the amateur will do well to study local conditions, including the soil, ere he makes a selection. However, there are very few soils in which the varieties named in our articles on each individual fruit will not thrive and give an abundant crop for all purposes.—W. J. G.

[It will be noticed that our contributor assumes that Orchards are to be sown with grass seed, but we should like to urge the wisdom of omitting the practice when circumstances allow. We are well aware of the happy associations connected with Orchards laid down in grass; our boys and girls love their games in the Orchard; a walk in a grass-laid Orchard in the spring when the trees are in full bloom has been said to be as near heavenly loveliness as it is possible on this earth to be; and lovers would be sorry indeed if Orchards were no longer laid down in grass; but even so it must be pointed out that grass has its disadvantages. It is so apt to get coarse, and then it will help to starve the trees, and rob their roots of air and warmth as well. Likewise it harbours millions of pests unless well looked after. We hope that new Orchards will be planted as described, but the soil left without the sowing of grass. Such would assist the trees greatly and keep them cleaner and more healthy, we feel sure. There would, however, be no objection to the planting of a few vegetables on the vacant ground beneath the trees, provided that only surface rooting crops were used.—Editor.]

ORCHID BORER.—See *Insect Pests*.

ORCHID HOUSE: Management of. Orchids as grown under glass in England comprise plants found in different countries and at different altitudes, hence the necessity of having houses maintained at different temperatures where a comprehensive collection has to be accommodated.

Orchids are divided into classes, namely, Warm, Intermediate, and Cool, and the respective houses are known by these names. The majority of Orchids known in our collections today, both species and hybrids, can be successfully cultivated in one or other of the houses named; but satisfactory results cannot be attained by attempting all classes of Orchids in one house.

Cool house Orchids comprise at the present day some of the most beautiful plants in cultivation. They are very popular, and rightly so, as

their beauties may be enjoyed without subjecting oneself to the, at times, uncomfortable temperatures of the warmer divisions. The old-time idea, that Orchids are difficult plants to grow, is an utter fallacy, and once the rudiments of their culture are mastered, there is no reason why anyone with the proper convenience should fail to grow them satisfactorily.

All plants grown by the artificial methods of glasshouses depend entirely upon the conditions provided for them, hence the necessity of paying strict attention to the details of temperature, atmospheric moisture, ventilation and shading, which make up the general routine of Orchid House Management. Watering and potting, although having some relation to the matter mentioned, are outside my province in this article, and are treated in the article *ORCHIDS: POTTING AND WATERING OF.* To simplify matters I propose to divide the year into two seasons: the spring and summer we will call the growing season; the autumn and winter the resting season. Rest is an absolute necessity to plant life, just as much as it is to the individual who attempts Orchid cultivation, hence the reason for keeping everything quiet or resting during the dull dark days of winter.

Temperatures.—The following temperatures may be regarded as averages; slight fluctuations will do no harm, but every effort should be made to keep the temperatures as steady as possible, since drastic changes are most harmful.

WARM HOUSE.—During the spring and summer months a temperature of 65–70° by night, and 70–80° by day, rising even higher with sunshine. In the autumn and winter 60–65° by night, and 65–70° by day. Warm House Orchids include: Ærides, Angræcum, Dendrobium, Phalænopsis, and Vanda.

THE INTERMEDIATE HOUSE.—This should be kept during summer at 60–65° by night, and 65–70° by day. During winter 55–60° by night, and 60–65° by day. Orchids for this House include: Cattleyas, Coelogynes, Brassocattleya, Cypripediums, Dendrobiums, Lælias, Læliocattleya, Miltonia, Oncidiums, Pleiones, etc.

THE COOL HOUSE.—This should be kept as near 60° as possible by day, and 55° by night during the summer season. In winter the night temperature may fall to 45° without injuring the plants; but 50° is the proper figure, and the temperature should be increased to 55° or 57° during the day. In this house may be grown many Orchids, chief among which may be named: Masdevallias, Nanodes, Odontiodas, Odontoglossums, and Oncidiums.

All the temperatures given are Fahr.

Atmospheric Moisture.—This is used to counteract the drying influences of the hot-water pipes necessary to heat the different houses, and to produce humid growing conditions, whilst the plants are making their growth, also to prevent attacks of insect pests, whilst the plants are at rest.

The paths, walls, and stages of the different houses should be damped with a syringe or water-pot two or three times a day, according to the outside conditions, and this is called "damping down." The general principle to be followed is: the greater the amount of heat, from whatever source, the greater amount of moisture is necessary. In the growing season a more humid atmosphere is desirable than when the plants are at rest. During hot weather the plants may be syringed or sprayed once or twice a day with clean soft water, which must be the same temperature as the house.

The chief atmospheric conditions to avoid are: a low temperature heavily charged with moisture; and a hot, dry temperature; both are the forerunner of disease and disaster.

Ventilation.—As nearly all Orchids come from hilly and mountainous countries, fresh air is indispensable to them, and should be admitted on all favourable occasions, particularly in the cooler divisions.

In the warm house with its higher temperature, though quite as beneficial to the plants, air cannot be so freely admitted, as a sudden lowering of the temperature may do much harm. Top ventilation must not be used to the extent of allowing the atmospheric moisture to escape too rapidly.

Air is best admitted chiefly through the bottom ventilators, which should be placed in the walls of the houses; the air, coming in contact thereby with the heat of the pipes, is warmed before reaching the plants. Fresh air should be admitted also during the night whenever the outside conditions will allow.

A proper balance of heat, light, air, and moisture must be maintained at all times according to the season of the year.

Light being a great factor in successful plant culture indoors, the glass should be kept clean at all times.

Shading.—Although all Orchids appreciate light, they are not able to stand strong sunshine or the direct rays of the sun; therefore, some means must be provided to protect them.

Wood lath blinds raised some 12 ins. from the roof answer the purpose better than any other material, and at the same time allow a current of air to pass between the blind and the roof, keeping the intense heat back and enabling an even temperature to be maintained.

Whatever material is used, it is better to be left in position all through the summer season, and should be so arranged as to be easily run up and down. In a changeable climate such as we have in Britain, a command over the shading is a distinct advantage to, and often an essential to the success of the Orchid cultivator.

J. T. B.

ORCHID SPOT DISEASE.—See *DISEASES OF PLANTS.*

ORCHID: Water Garden Species.—See *WATER GARDEN: PLANTS FOR THE.*

ORCHIDS.

Acineta.—Plants of stout habit, with slightly furrowed bulbs, bearing large plicate leaves. Flowers produced in drooping racemes from base of bulb. Natives of Tropical America and Mexico.

A. Barkeri.—Large flowers, golden-yellow, lip spotted dark red; summer. Height, 18–24 ins.

A. densa.—A beautiful species; sepals bright yellow, petals crimson-spotted, lip-marked with deep red; spring. Height, 12–18 ins.

A. Humboldtii.—Flowers chocolate-purple, petals rose, pendent spikes 2 ft. long; spring. Height, 12–18 ins.

Ada.—Represented in gardens by *A. aurantiaca*, a neat plant bearing erect spikes of cinnabar-orange flowers produced in late winter and spring. Native of Colombia. Height, 1 ft.

Ærides.—A genus of evergreen plants, with erect stems on which the foliage is arranged distichously. Flowers borne in pendent racemes, of wax-like texture, often scented. Natives of India, Malay Archipelago, and Eastern Asia.

A. affine.—Flowers rose, lip with darker spots; summer. Height, 10–20 ins.

A. crispum.—Flowers scented, white, rose-tipped, lip rose-purple; summer. Height, 2–5 ft.

A. Lawrenceæ.—Very handsome, large flowers waxy-white, tipped with purple; autumn.

A. maculosum.—Branched racemes of fragrant flowers, light-rose, purple spotted; summer.

A. odoratum.—Flowers creamy-white, marked with magenta; summer. Height, 2–4 ft.

A. Sanderianum.—Very showy, spike 2 ft., creamy-white, magenta marked; summer. Height, 1–4 ft.

A. virens.—Fragrant, flowers whitish, marked with purple; summer. Height, 1–3 ft.

Angræcum.—Remarkable epiphytes with opposite foliage, from the axils of which the flowers are produced. The long slender spur to the lip is a noteworthy feature. Natives of Tropical Africa and Madagascar.

A. citratum.—Neat habit, flowers creamy-white, borne on arching spikes; summer.

A. eburneum.—Leaves stiff, about 18 ins. long, flowers large, pure white; summer. Height, 1–3 ft.

A. infundibulare.—Elegant and rare, broad lip of flower pure white, the long funnel-shaped spur pale green; summer.

A. Kotschyi.—Many flowered pendulous racemes, creamy-white, very long spur red-brown; autumn.

A. Sanderianum.—Stems, 10–15 ins., drooping scapes of pure white flowers; summer.

A. sesquipedale.—Flowers very large, ivory-white, spur about a foot long; winter. Height, 1–3 ft.

Anguloa.—Large handsome-flowered plants producing cradle-shaped, fleshy flowers from the base of the bulb. The broad leaves plicate and erect, from 18–24 ins. high. Natives of Colombia.

A. Cliftonii.—Sepals and petals lemon-yellow with dark purple base, lip brownish-yellow; spring.

A. Clowesii.—Fragrant flowers, golden-yellow, lip whitish; spring.

A. eburnea.—Sepals and petals pure white, lip slightly pink-spotted; spring.

A. Ruckeri.—Sepals and petals yellow, crimson-spotted, lip crimson; summer.

A. uniflora.—Flowers white, flushed with pink; summer.

Ansellia.—Noble plants, producing large panicles of flowers. Natives of Tropical Africa and Natal.

A. africana.—Flower spike borne from apex of bulb, yellow, spotted with red; winter. Height, 3 ft.

Arachnanthe.—Closely allied to VANDA. Stems leafy, bearing loose racemes of showy flowers. Natives of Malay Archipelago.

A. Cathcartii.—Tall scrambling habit, flowers large and fleshy, yellowish, banded with red, lip white; summer.

A. Lowii.—Flowers produced on spikes which are often 12 ft. long, yellowish, blotched with chocolate-red; autumn. Height, 2–10 ft.

Arpophyllum.—A small genus with slender bulbs and narrow leaves. The numerous flowers are produced in dense, cylindrical racemes. Natives of Mexico and Central America.

A. giganteum.—Flowers rose-purple, spike about 12 ins. long; spring. Height, 20–36 ins.

Bifrenaria.—Allied to MAXILLARIA. Bulbs usually stout, angled, rather pointed, bearing stiff leaves. Natives of Brazil and British Guiana.

B. aurantiaca.—Flowers in racemes, yellow, orange spotted; autumn and winter. Height, 6–9 ins.

B. Harrisoniæ.—Flowers large, ochreous yellow, scented; spring. Height, 6–9 ins.

Brassavola.—Comprising about a dozen species. Bulbs flat or cylindrical, and bearing fleshy leaves. Flowers produced on apex of bulb. Natives of Central and Tropical America.

B. Digbyana.—Bulbs about 6 ins. high, bearing a fleshy leaf, flower large, greenish-white, lip broad and deeply fringed; autumn.

B. glauca.—Neat habit, flowers white, shaded with green; spring.

B. nodosa.—Flower white, lip spreading; autumn. Height, about 12 ins.

Brassia.—Resembling the genus Oncidium, but differing in the narrow, very elongated sepals and petals. The species inhabit Tropical America, Brazil, and the West Indies.

B. maculata.—Spikes, 9–18 ins. long, flowers light yellow, brown spotted; spring. Height, 9–12 ins.

B. verrucosa.—Spikes about 2 ft. long, flowers greenish, blotched with dark purple. Height, 9–15 ins.

Brassocattleya.—Derived through the intercrossing of the genera Brassavola and Cattleya. By using *Brassavola Digbyana* many elegant and attractive flowers have been produced, the main distinguishing feature being the unusually large and prettily fringed labellum.

Brassolælia.—Obtained by uniting the genera Brassavola and Lælia. Many excellent hybrids have resulted when *Brassavola Digbyana* has been one of the parents.

Brassolæliocattleya.—A combination of the genera Brassavola, Lælia, and Cattleya; numerous hybrids in this section have been produced, the flowers generally being remarkably attractive when *Brassavola Digbyana* is included.

Broughtonia.—This genus is usually represented in gardens by *B. sanguinea*, of compact habit, roundish bulbs, from the apex of which the arched panicles of blood-coloured flowers are produced; summer.

Bulbophyllum.—A genus of widely distributed and curious plants, chiefly of botanical interest and requiring warm treatment.

B. barbigerum.—Dwarf habit, small bulbs, the spike carrying about eight flowers, the lip like a tuft of hair, so delicate that it moves with the slightest breath, which gives it the appearance of a living thing; spring and summer.

B. Lobbii.—Flowers comparatively large, buff-yellow, the upper sepal marked with purple; summer.

Calanthe.—Terrestrial plants divided into two sections—evergreen and deciduous, the latter being more largely cultivated. Flower spikes produced from base of bulb.

C. masuca.—Evergreen, height 20–30 ins., flowers deep violet and purplish; summer.

C. rosea.—Deciduous, typically rose-pink, but varying; winter.

C. veratrifolia.—Evergreen, flowers white, lip deeply cut; summer.

C. vestita.—Deciduous, flowers creamy-white, sometimes with a coloured eye; winter.

Calanthe Hybrids.—Numerous and useful, the best known being *Sedenii* (Veitchii × vestita), and *Veitchii* (rosea × vestita). *C. Dominyi* (furcata × masuca) is of interest as being the first Orchid hybrid artificially raised.

Cattleya.—A most important and popular genus, dedicated to Wm. Cattleya, who died in 1832. Flowers large, showy, produced on apex of the bulbs, and in the bud state protected by a sheath. Natives of Tropical America.

C. amethystoglossa.—Bulbs 1½–3 ft.

high, flowers light rose, purple spotted, lip magenta-purple ; spring.

C. bicolor.—Bulbs slender, 15–20 ins. high, flowers bronzy-green, lip rose-purple ; late summer.

C. Bowringiana.—Stems 9–18 ins. high, swollen at base, spikes of rose-purple ; autumn.

C. citrina.—Dwarf habit, bulbs globular, flowers pendent, bright yellow, fragrant ; spring.

C. Dowiana.—Bulbs club-shaped, flowers nankeen-yellow, lip crimson-purple, streaked with gold ; autumn.

C. Eldorado.—Bulbs round, smooth, flowers blush-white, lip purplish-magenta ; early summer.

C. Gaskelliana.—Bulbs club-shaped, flowers rose-flushed, lip amethyst-purple ; late summer.

C. granulosa.—Stems terete, two-leaved, 15–30 ins. high, flowers olive-green, lip white and crimson ; late summer.

C. Harrisoniana.—Bulbs slender, 12–24 ins. high, flowers rose-lilac ; summer.

C. intermedia.—Bulbs slender, 10–20 ins. high, flowers rose, lip purple ; summer.

C. labiata.—Bulbs club-shaped, 6–10 ins. high, flowers deep rose, lip crimson-purple ; late autumn.

C. Lawrenceana.—Bulbs 12–15 ins. high, flowers rose-purple ; spring.

C. Leopoldii.—Bulbs 1½–3 ft. high, flowers bronze, lip crimson-purple ; summer.

C. Loddigesii.—Bulbs slender, 12–24 ins. high, flowers lilac-rose ; late summer.

C. Luddemanniana.—Bulbs thick, flowers light rosy-purple, lip amethyst and white ; summer.

C. maxima.—Flowers rose, lip veined dark crimson ; winter. Height, about 15 ins.

C. Mendelii.—Large flowers, blush-rose, lip rich magenta ; early summer.

C. Mossiæ.—Flowers large and variable, light rose, lip crimson and rose with yellow markings ; early summer.

C. Percivaliana.—Flowers of medium size, deep rose, lip richly coloured ; early winter.

C. Rex.—Flowers creamy-white to yellow, lip crimson ; summer.

C. Schilleriana.—Flowers large, rosy-brown, lip striped with purple ; summer.

C. Schroderæ.—Bulbs club-shaped, flowers light rose, deeper on lip ; spring.

S. Skinneri.—Stems 9–18 ins. high, flowers rose-purple ; early summer.

C. Trianæ.—Flowers large, blush, lip purple-crimson ; early spring.

C. Warneri.—Flowers large, deep rose, lip rich crimson ; summer.

C. Warscewiczii.—Flowers very large, dark rose, lip broad, magenta-purple ; summer.

Cattleya Hybrids.—Of the numerous hybrids in this genus the most useful are :—

Adula (bicolor × Hardyana) ; *Atalanta* (Leopoldii × Warscewiczii) ; *Empress Frederick* (Mossiæ × Dowiana aurea) ; *Fabia* (labiata × Dowiana aurea) ; *Hardyana* (Warscewiczii × Dowiana aurea) ; *iridescens* (bicolor × Eldorado) ; *Iris* (bicolor × Dowiana aurea) ; *Lord Rothschild* (Gaskelliana × Dowiana aurea) ; *Maggie Raphael* (Dowiana aurea × Trianæ alba) ; *Mantinii* (Bowringiana × Dowiana aurea) ; *Octave Doin* (Mendelii × Dowiana aurea) ; *Portia* (Bowringiana × labiata) ; *Sybil* (iridescens × Dowiana aurea) ; *Tityus* (Enid × Octave Doin) ; and *Venus* (Iris × Dowiana aurea).

Chysis.—Deciduous, with stout, fleshy bulbs about a foot in height, and broad lanceolate leaves. Flowers carried on short racemes produced from the young growths.

C. aurea.—Sepals and petals yellow, lip tawny, marked with crimson ; early summer.

C. bractescens.—Sepals and petals white, lip yellowish, with crimson markings ; spring.

C. lævis.—Sepals and petals orange-yellow, lip yellow, crimson blotched ; early summer.

Cirrhopetalum.—An interesting genus, dwarf habit, the inflorescence usually umbel-like, the lateral sepals considerably developed. Allied to BULBOPHYLLUM.

C. Medusæ.—Apex of spike producing a dense cluster of small creamy flowers.

C. picturatum.—Flowers yellowish-green, upper sepal red spotted ; autumn.

C. robustum.—Robust, flowers large, glossy, yellow, lip chocolate-red ; summer.

C. Rothschildianum.—Flowers 5 ins. long, dark red-purple, with traces of yellow ; autumn.

Cochlioda.—Allied to ODONTOGLOSSUM, noteworthy on account of the various meritorious hybrids produced by *C. Nætzliana.* Natives of Peru and Ecuador.

C. Nœtzliana. — Habit dwarf, flowers rich orange-scarlet; winter and spring.

C. rosea. — Flowers rose-carmine, column white; winter.

C. sanguinea.—Flowers rose-pink, lip paler; autumn.

C. vulcanica.—Erect spikes of dark rose flowers, lip paler; spring.

Cœlia.—Bulbs globose, with two or three narrow leaves. Flowers produced on erect spikes from base of bulb. Natives of South America.

C. bella.—Flowers large, creamy-white, tipped with magenta, lip yellow; autumn.

C. macrostachya.—Flowers rose-red, in tall, erect spikes; late summer.

Cœlogyne.—A useful genus widely distributed throughout the East, *C. cristata* being one of the most popular Orchids cultivated. Flowers usually produced from the young growths.

C. barbata.—Spike erect, flowers pure white, lip bearded with brown hairs; winter.

C. cristata.—Racemes of pure white flowers, centre of lip orange-yellow; winter to spring.

C. Dayana.—Scapes pendent, 2–3 ft., flowers ochre-yellow, lip white and chocolate; early summer.

C. flaccida.—Drooping racemes of whitish flowers, lip with yellow disc; spring.

C. pandurata.—Bulbs set widely apart, flowers large, greenish, lip warted, blotched with black; summer.

C. Sanderæ.—Erect spike of whitish flowers, orange blotch on lip; summer.

C. speciosa.—Flowers large, tawny, lip yellow outside, brown within; various.

Colax.—A small genus related to Lycaste and Maxillaria.

C. jugosus. — Bulbs 2–3 ins. high, leaves 6–9 ins., flowers white, marked with purple; early summer. Native of Brazil.

Coryanthes.—Remarkable for the extraordinary structure of the flowers, part of which is in the form of a pouch so arranged as to catch a secretion dropped by two lobes at the base of the column. Natives of Tropical South America.

C. macrantha.—Flowers rich yellow, speckled with red; summer.

C. maculata.—Flowers light yellow, spotted with crimson; summer.

Cycnoches.—Stems thick and fleshy, 6–10 ins. high, bearing three or four large leaves, which decay when the bulbs are completed. On account of the long, slender, arching column the flowers resemble the Swan, from which the generic name is derived.

C. chlorochilon. — Flowers large, yellowish-green, lip white, with blackish blotch at base; summer.

Cymbidium.—A popular genus with short, stout bulbs sheathed with long, narrow foliage. The erect or semi-pendent spikes are produced from the base of the bulb, and carry numerous flowers. During recent years the hybridist has added many beautiful novelties.

C. eburneum.—Spikes one to three flowered, ivory-white, centre of lip yellow; winter and early spring.

C. giganteum.—Spikes with seven to fifteen flowers, large, yellowish-green, striped with red; winter.

C. grandiflorum. — Flowers large, sepals and petals green, lip yellow, marked with crimson-purple; winter and spring.

C. insigne.—Spike 3–4 ft. long, carrying many flowers, light rose, lip marked with rose-purple; spring.

C. Lowianum.—Spikes long, fifteen to thirty flowers, yellowish-green, lip with crimson blotch; early spring.

C. Parishii.—Erect spikes of three to five flowers, ivory-white, lip blotched with crimson-purple; spring.

C. tigrinum.—Dwarf habit, spikes drooping, flowers olive-green, lip marked with purple; autumn.

C. Tracyanum. — Flowers large, yellowish, lip marked with crimson; summer.

C. Wilsonii.—Spike slender, about five flowers, light green, lip yellowish, marked with red-brown; late winter.

Cymbidium Hybrids.—The following selection embraces the finest hybrids:—

Alexanderi (eburneo-Lowianum × insigne); *Doris* (insigne × Tracyanum); *Lady Colman* (eburneo-Lowianum × Tracyanum); *Pauwelsii* (insigne × Lowianum); *rosefieldense* (grandiflorum × Tracyanum); *Schlegelii* (insigne × Wiganianum); *Wiganianum* (eburneum × Tracyanum); and *Woodhamsianum* (eburneo-Lowianum × Lowianum).

Cyperorchis. — These plants are allied to, and often included in, the genus Cymbidium, but differ in having the segments of the flowers more or less united at their basal halves, and hence do not open so fully.

C. elegans. — Racemes sub-erect, flowers closely set, straw-yellow; autumn.

C. Mastersii.—Spikes erect, flowers ivory-white, lip rose-spotted; winter.

Cypripedium.—A well-known and largely cultivated terrestrial genus containing numerous species and a multitude of hybrids. Many have variegated foliage, while the handsome dorsal sepal and the singular pouch-like lip render them ever attractive.

C. barbatum.—Foliage tessellated, dorsal sepal white, flushed and striped with purple; summer.

C. bellatulum.—Leaves tessellated, flowers white, spotted with dull purple; summer.

C. Boxallii.—A dark variety of *C. villosum.*

C. callosum. — Leaves marbled, dorsal sepal white, green at base, striped with crimson; spring and summer.

C. Chamberlainianum.—Leaves dark green, dorsal sepal with rose markings, petals twisted; various.

C. Charlesworthii.—Leaves narrow, green, dorsal sepal broad, rose, with darker veining; late summer.

C. concolor. — Leaves marbled, flowers light yellow, speckled with crimson; early summer.

C. Curtisii. — Foliage tessellated, flowers bold, dorsal sepal greenish, with darker veining; spring and summer.

C. Fairrieanum. — Leaves green, dorsal sepal white, veined with purple, petals deflexed; summer.

C. hirsutissimum.—Leaves green, flowers large, dorsal sepal dark purplish-green; spring.

C. insigne.—Leaves green, dorsal sepal green, with brown-purple spots, apex white; winter.

C. Lawrenceanum.—Foliage tessellated, flowers large, dorsal sepal white, with purplish veins; early summer.

C. niveum.—Habit dwarf, flowers satiny-white, round in outline; summer.

C. Rothschildianum.—Leaves about 2 ft. in length, dorsal sepal yellowish, with black stripes, petals horizontal and long; summer.

C. Spicerianum. — Leaves green, dorsal sepal white, with median purple stripe; winter.

C. Stonei.—Leaves green, dorsal sepal white, striped with blackish-crimson, petals 5 ins. long; autumn.

C. superbiens.—Foliage tessellated, dorsal sepal whitish, green veined; summer.

C. tonsum. — Foliage tessellated, dorsal sepal greenish, with darker veining; autumn.

C. venustum. — Foliage mottled, dorsal sepal greenish-white, with purple stripes; spring.

C. villosum.—Foliage green, flowers large, glossy, dorsal sepal brown and green; early spring.

Cypripedium Hybrids. — Of the immense number of hybrids raised in gardens the following are among the most useful:—

Actæus (insigne × Leeanum); *Arthurianum* (insigne × Fairrieanum); *aureum* (nitens × Spicerianum); *Draco* (Hera × insigne); *Helen II* (bellatulum × insigne); *Hera* (Boxallii × Leeanum); *Lathamianum* (Spicerianum × villosum); *Leander* (Leeanum × villosum); *Leeanum* (insigne × Spicerianum); *Leoniæ* (callosum × insigne); *Lord Wolmer* (Hera × Leeanum); *Mons. de Curte* (Boxallii × insigne); *Morganiæ* (Stonei × superbiens); *nitens* (insigne × villosum); *picturatum* (Spicerianum × superbiens); *Priam* (insigne × Niobe); *Psyche* (bellatulum × niveum); *Rossettii* (insigne × Maudiæ); *Tracyanum* (aureum × Leeanum); *Troilus* (insigne × nitens); and *W. R. Lee* (Rothschildianum × superbiens).

Cyrtopodium. — Handsome plants with tall bulbs, having long, strap-shaped leaves. Flower spike tall and branching, produced from base of bulb.

C. Andersonii.—Stems 3–4 ft. high, spike taller, flowers yellowish tinged with green; spring.

C. punctatum.—Stems 2–3 ft. high, flowers yellow, marked with red; spring.

Dendrobium.—A large genus distributed throughout the East, from India, through Burma, Assam, and to the Philippines and Australia. Bulbs vary from three inches to several feet high. Flowers produced in clusters of two or three from the nodes of the bulb, as in *D. nobile*; on erect apical spikes, as in *D. phalænopsis*; and in drooping apical clusters, as in *D. densiflorum.*

D. acuminatum. — Bulbs small, quadrangular, spike from apex, flowers rose-purple; late winter.

D. atroviolaceum.—Flowers in terminal spikes, creamy-white, spotted with purple; winter.

D. aureum.—Flowers from nodes, fragrant, amber, lip marked with brown; early spring.

D. bigibbum.—Flowers in terminal spikes, magenta-purple; late autumn.

D. Brymerianum.—Flowers large, in

short racemes, golden, lip deeply fringed; spring.

D. crassinode. — Stems knotted, flowers from nodes, white tipped with purple; late winter.

D. Dearei.—Flowers from apex, in clusters, large, white; early autumn.

D. densiflorum.—Bulbs stout, flowers in dense pendulous trusses, yellowish; spring.

D. Falconeri. — Stems knotted, flowers from nodes, white tipped with purple; spring.

D. fimbriatum—Flowers in pendulous racemes, orange-yellow, lip fimbriated; spring.

D. formosum.—Bulbs black-haired, flowers in apical clusters, large, white; autumn.

D. infundibulum. — Stems black-haired, flowers in apical clusters, white; spring and summer.

D. Jamesianum. — Stems black-haired, flowers in apical clusters, white, lip marked with cinnabar; spring and summer.

D. macrophyllum. — Stems stout, flowers in terminal spikes, yellowish, lip marked with purple; summer.

D. nobile.—Flowers from nodes, whitish, tipped with rose-purple, lip blotched; spring.

D. phalænopsis. — Flowers in terminal spikes, deep rose; autumn.

D. Pierardii.—Stems slender, pendent, flowers from nodes, blush-white, lip purple-veined; spring.

D. Sanderæ.—Stems tall, racemes on upper part, flowers white, lip lined with green; early autumn.

D. speciosum. — Stems stout, flowers in terminal spikes, pale yellow; spring.

D. suavissimum. — Stems stout, flowers in terminal racemes, golden-yellow, lip blotched; spring.

D. superbum. — Stems pendent, flowers from nodes, magenta-rose; spring.

D. thyrsiflorum.—Stems thick, flowers in drooping thyrses, whitish, lip orange; spring.

D. Victoria Regina.—Flowers from nodes, whitish, outer portions purplish-blue; autumn.

D. Wardianum. — Stems stout, flowers from nodes, waxy-white, tipped with amethyst purple; spring.

Dendrobium Hybrids.—The following are all worthy of cultivation :—

Ainsworthii (aureum × nobile); *chessingtonense* (aureum × Wiganiæ); *Euryalus* (Ainsworthii × nobile); *melanodiscus* (Findlayanum × Ainsworthii); *Ophir* (signatum × aureum); *Schneiderianum* (Findlayanum × aureum); *Thwaitesiæ* (Ainsworthii × Wiganiæ); *Venus* (nobile × Falconeri); *Wiganiæ* (signatum × nobile); and *Wiganianum* (Hildebrandii × nobile).

Disa.—Terrestrial plants with tuberous roots, producing leafy, erect flower spikes from their centre. Natives of South Africa.

D. grandiflora.—Flower stem tall, large, scarlet; spring and summer.

D. racemosa.—Flower stem with many blooms of rose-purple; summer.

D. Veitchii.—Garden-raised hybrid between grandiflora and racemosa.

Epicattleya.—Garden-raised hybrids between the two genera Epidendrum and Cattleya.

Epidendrum. — A large genus, variable as to habit, size, and shape of the flowers. The majority are only of botanical interest.

E. cochleatum.—Spike erect, flowers greenish, lip shell-shaped, blackish; various.

E. fragrans.—Scapes short, erect, flowers creamy, lip streaked with red-purple; late summer.

E. nemorale. — Spike branching, flowers large, rosy-mauve; summer.

E. prismatocarpum.—Spikes erect, flowers cream-yellow, blotched with purple; summer.

E. radicans.—Stems long, slender, producing aerial roots, flowers orange-scarlet; various.

E. vitellinum.—Bulbs ovoid, flowers cinnabar-red; autumn.

Epilælia. — Garden-raised hybrids between Epidendrum and Lælia.

Epiphronitis. — Garden-raised hybrids between Epidendrum and Sophronitis, generally represented by *E. Veitchii* (E. radicans × S. grandiflora).

Eulophia.—Terrestrial plants, widely distributed, represented in gardens by *E. guineensis*, which has pear-shaped bulbs bearing large, plicate, deciduous leaves; flowers purplish-green, lip white, striped with crimson; summer.

Eulophiella. — Handsome plants, natives of Madagascar, and represented in gardens by the following :—

E. Elizabethæ.—Bulbs at intervals on rhizomes, leaves narrow, spikes 1–2 ft. long, flowers fleshy, white; spring.

E. Peetersiana.—Habit much larger than above, spikes 3–5 ft. high, flowers 3–4 ins. across, rose-purple; spring.

Grammatophyllum. — Robust epiphytes, flowers from long scapes, pro-

duced from base of bulb, which vary considerably in size.

G. Fenzlianum.—Bulbs short, stout, flowers yellow and green, blotched with chocolate ; summer.

G. multiflorum. — Bulbs short, flowers brownish-purple, lip yellowish, streaked with chocolate ; summer.

G. speciosum.—Bulbs 4–10 ft. high, spike 5 ft. long or more, flowers yellow, blotched with purple ; various.

Habenaria. — Terrestrial, tuberous rooted, deciduous and widely distributed. Foliage grows in a rosette-like form, the leafy flower spike produced from the centre.

H. carnea.—Spike 1 ft., flowers flesh coloured, lip deeply cleft ; autumn.

H. rhodocheila.—Flowers medium size, lip vermilion ; summer. Height, 6–12 ins.

H. Susannæ.—Flowers large, pure white, lip three-lobed ; autumn. Height, 18–36 ins.

Houlletia. — A small genus, bulb bearing a single, large, plicate leaf, and producing from its base an erect spike of six to twelve flowers.

H. Brocklehurstiana.—Spike 12–24 ins. high, flowers chocolate brown, lip yellow, spotted ; summer.

H. odoratissima.—Of smaller habit than the above, flowers brownish-red, lip tipped with yellow ; summer.

Lælia.—A genus of pretty Orchids, differing from Cattleya by having eight pollinia instead of four. Natives of Mexico and Brazil.

L. albida.—Bulbs ovate, spikes five to eight flowered, white, lip rose flushed ; winter.

L. anceps. — Bulbs 3–6 ins. high, spikes tall, flowers rose-lilac, lip crimson-purple. There are many varieties, some with white segments.

L. autumnalis.—Bulbs 2–4 ins. high, tall spikes of rose-purple flowers ; late autumn.

L. cinnabarina.—Bulbs 6–9 ins. high, erect spikes of cinnabar-red flowers ; spring.

L. crispa. — Bulbs 6–12 ins. high, flowers large, whitish, lip crisped ; summer.

L. flava.—Bulbs 3–6 ins. high, erect spikes of canary-yellow flowers ; summer.

L. Jongheana.—Bulbs short, flowers large, rose-purple, lip with yellow ridges ; early spring.

L. pumila.—Habit dwarf, flowers large, rose-purple, lip purplish-crimson ; autumn.

L. purpurata.—Bulbs with leaf 20–30 ins. high, flowers large, rose-white lip crimson-purple ; spring.

L. superbiens.—Bulbs 10–15 ins. high, two-leaved, spikes long, flowers deep-rose, lip crimson ; winter.

L. tenebrosa. — Flowers reddish-brown, lip dusky purple ; spring.

Læliocattleya.—A very popular and numerous section obtained by crossing the various species of Lælia and Cattleya. No less than 1500 different crosses have been named. The best include :—

Aphrodite (C. Mendelii × L. purpurata) ; *Baroness Schroder* (L. Jongheana × C. Trianæ) ; *bella* (C. labiata × L. purpurata) ; *bletchleyensis* (C. Warscewiczii × L. tenebrosa) ; *callistoglossa* (C. Warscewiczii × L. purpurata) ; *Canhamiana* (C. Mossiæ × L. purpurata) ; *Dominiana* (C. Dowiana × L. purpurata) ; *elegans* (C. Leopoldii × L. purpurata) ; *Epicasta* (L. pumila × C. Warscewiczii) ; *Fascinator* (C. Schroderæ × L. purpurata) ; *Golden Glory* (C. Mossiæ × L.-C. Zephyr) ; *Haroldiana* (C. Hardyana × L. tenebrosa) ; *Henry Greenwood* (C. Hardyana × L.-C. Schilleriana) ; *Martinetii* (C. Mossiæ × L. tenebrosa) ; *Ophir* (C. Dowiana × L. xanthina) ; *St. Gothard* (C. Hardyana × L.-C. Gottoiana) ; *Thyone* (L.-C. Ophir × C. Dowiana aurea) ; and *Wellsiana* (L. purpurata × C. Trianæ).

Lowiara.—A combination of the genera Brassavola, Lælia, and Sophronitis, the first raised being *L. insignis* (B.-L. Helen × S. grandiflora).

Lycaste.—A popular genus of easy culture, for the most part natives of Central America. Characterised by stout, ovoid bulbs bearing plicate leaves.

L. aromatica.—Habit dwarf, flowers golden-yellow ; winter.

L. cruenta.—Habit dwarf, flowers yellow, lip blotched ; spring.

L. Deppei.—Flowers large, sepals green, petals white, lip yellow, red spotted ; winter.

L. gigantea.—Bulbs and flowers large, olive-green, lip purplish ; winter.

L. macrophylla. — Flowers large, sepals olive-green, shaded red, petals white, rose-spotted ; late winter.

L. Skinneri.—Flowers large, handsome, light rose, petals darker, lip whitish, crimson spotted ; winter.

Masdevallia.—An interesting genus of small tufted plants, devoid of bulbs, natives of South America. The sepals are the prominent part of the flower, usually extending into a tail-like form.

M. Chimæra.—Flowers large, variable, yellowish, thickly spotted with reddish-purple; spring and summer.

M. Harryana.—Flowers blood-crimson, many varieties; spring.

M. ignea.—Flowers large, cinnabar-red; spring.

M. polysticta.—Flowers white, purple spotted; spring.

M. Schroderiana.—Handsome flowers, rose-purple and white, long yellow tails; summer.

Maxillaria.—Widely distributed throughout Central America. Bulbs comparatively small, producing single flowered scapes from the base. While some species have short rhizomes and clustering bulbs, others have ascending rhizomes with the bulbs farther apart.

M. grandiflora.—Large flowers, milk-white, lip yellow, marked with crimson; spring.

M. luteo-alba.—Flowers large, white and tawny-yellow; various.

M. Sanderiana.—Flowers about 6 ins. across, white, marked with blood-red; spring.

M. tenuifolia.—Bulbs at intervals on ascending rhizome, leaves narrow, flowers reddish, marked with yellow; spring.

M. venusta.—Flowers large, white, lip yellow; winter.

Miltonia.—Large flowered epiphytes, producing flower spikes from base of bulb. Natives of Brazil and Colombia.

M. phalænopsis.—Leaves narrow, spikes of rose-white flowers, lip blotched with purple; late spring.

M. spectabilis.—Bulbs at intervals on rhizome, flowers rose, broad lip, purple; summer.

M. vexillaria.—Bulbs flat, oval, spikes of large lilac-rose flowers; spring.

M. Warscewiczii.—Bulbs flattish, erect spikes of reddish flowers, lip rosy-purple; spring.

Miltonioda.—Hybrids obtained by crossing Cochlioda and Miltonia.

Mormodes.—Remarkable for the curious structure of their flowers, which are produced on stout scapes from the base of the bulb.

M. luxatum.—Flowers yellowish-green, marked with brown; summer.

M. pardinum.—Flowers light-yellow, spotted with brownish-red; summer.

Odontioda.—A beautiful section of garden-raised hybrids between the genera Odontoglossum and Cochlioda. The majority include *C. Nætzliana*, and yield many-flowered spikes of varying scarlet and reddish tints.

Odontocidium.—Garden-raised hybrids between Odontoglossum and Oncidium.

Odontoglossum.—The most popular section of cool house Orchids. Bulbs usually ovoid, leaves at base and apex, spike produced from base. Though natives of tropical countries, the plants are found at considerable altitudes, where the atmosphere is cool and moisture abundant.

O. Adrianæ.—Natural hybrid between crispum and Hunnewellianum; spring.

O. Andersonianum.—Natural hybrid between crispum and gloriosum; spring.

O. aspersum.—Natural hybrid between maculatum and Rossii; winter.

O. bictoniense.—Bulbs flattish, oval, flowers yellowish-green, blotched with brown; autumn.

O. Cervantesii.—Dwarf habit, flowers round, whitish, with concentric red bars; spring.

O. cirrhosum.—Segments of flowers tapering, white, spotted with purplish crimson; spring.

O. citrosmum.—Spike pendulous, flowers round, rose-white; spring.

O. Coradinei.—Natural hybrid between crispum and Lindleyanum; spring.

O. cordatum.—Flowers chestnut-brown, petals yellow; spring.

O. coronarium.—Bulbs large, at intervals on rhizome, flowers round, glossy, red-copper, lip yellow; spring.

O. crispum.—Arching spikes of white flowers, sometimes tinged with rose or blotched with purple; spring.

O. Edwardii.—Bulbs long, spike tall, flowers small, numerous, purplish-mauve; spring.

O. excellens.—Natural hybrid between Pescatorei and triumphans; spring.

O. gloriosum.—Flowers with narrow segments, yellow, brown-spotted; spring.

O. grande.—Flowers 5–7 ins. across, bright yellow, barred with chestnut-brown; autumn.

O. Hallii.—Flowers yellow, blotched with chocolate-red, lip broad, fringed; spring.

O. Harryanum.—Flowers large, sepals brown and yellow, petals whitish and mauve-purple, lip broad with prominent crest; spring.

O. hastilabium.—Spikes erect, 3–5 ft., flowers yellow, shaded with green, spotted with purplish-brown; summer.

O. Hunnewellianum.—Flowers small,

yellow, heavily spotted with dark brown; spring.

O. Insleayi.—Flowers large, yellow, barred with chestnut-red; late summer.

O. Kegeljani. — Flowers yellow, blotched with brown; spring.

O. Lindleyanum. — Flowers with narrow segments, yellow, with brown markings; spring.

O. luteopurpureum.—Flowers large, chestnut-brown, marked with yellow, lip brown; spring.

O. maculatum.—Sepals brown, petals yellow, lip yellowish-white; spring.

O. nævium. — Segments narrow, white, spotted with red-purple; summer.

O. nebulosum.—Flowers roundish, white, with red-brown spots; late spring.

O. odoratum.— Segments narrow, yellow, with brown-red blotches; winter.

O. Pescatorei. — Spikes branching, flowers white, lip with broad apex; spring.

O. pulchellum.— Erect spikes of small, pure white flowers; spring.

O. Rossii.—Dwarf, flowers white or rose, with dark brown spotting; winter.

O. Ruckerianum.—Natural hybrid between crispum and gloriosum; spring.

O. triumphans. — Flowers golden-yellow, blotched with brown; spring.

O. Uro-Skinneri.—Spike erect, sepals and petals greenish, marked with brown, lip large, rose; spring.

O. Wilckeanum.—Natural hybrid between crispum and luteopurpureum; spring.

Odontoglossum Hybrids. — A large number of attractive hybrids have been raised during recent years. The following are among the most useful :— *Ardentissimum* (crispum × Pescatorei); *Dora* (Lambeauianum × Pescatorei); *eximium* (ardentissimum × crispum); *Fascinator* (Adrianæ × crispum); *illustrissimum* (ardentissimum × Lambeauianum); *Lambeauianum* (Rolfeæ × crispum); *MacNabianum* (Harryanum × Wilckeanum); *Ossulstonii* (crispo-Harryanum × Pescatorei); *percultum* (Rolfeæ × ardentissimum); *Queen Alexandra* (Harryanum × triumphans); *Rolfeæ* (Harryanum × Pescatorei); *Thompsonianum* (Edwardii × crispum); and *Vuylstekei* (harvengtense × Wilckeanum).

Odontonia.—Garden-raised hybrids between the genera Odontoglossum and Miltonia.

Oncidioda.—Garden-raised hybrids between the genera Oncidium and Cochlioda.

Oncidium.— A large and varied genus, distributed throughout South America and the West Indies.

O. ampliatum. — Bulbs broad, flowers 1½ ins. across, yellow; spring.

O. bicallosum. — Bulbless, leaves leathery, flowers yellow; winter.

O. Cavendishianum. — Bulbless, leaves leathery, flowers 1–2 ins. across, yellow, spotted with red; spring.

O. concolor. — Spikes drooping, canary-yellow; early summer.

O. crispum.—Flowers large, brownish, segments crisped; various.

O. curtum.—Spike 2–3 ft. high, branched, flowers brown and yellow; spring.

O. flexuosum.—Bulbs at intervals on ascending rhizome, large yellow lip; summer.

O. Forbesii.—Flowers large, segments broad, chestnut-brown, yellow markings; autumn.

O. incurvum.—Spikes 3–6 ft. long, flowers small, rose-pink, tipped with white; autumn.

O. Kramerianum.—Spike 2–3 ft., flowers large, lower sepals and lip yellow, marked with red-brown; various.

O. macranthum.—Spike several feet long, flowers large, sepals brownish, petals yellow, lip white and purple; early summer.

O. Marshallianum. — Lip large, spreading, bright yellow; early summer.

O. ornithorhynchum.—Spikes 1–2 ft., flowers small, rose-lilac; winter.

O. papilio.—Resembling *O. Krameri-anum*, but upper part of scape is flattened; various.

O. tigrinum.—Spikes 2–4 ft., flowers large, lip spreading, yellow; late autumn.

O. varicosum. — Spikes 3–5 ft., branched, lip large, bright yellow; autumn.

Peristeria.—Characterised by stout bulbs, from the base of which the flower spikes are produced; broad, plicate leaves, and large fleshy flowers of globular shape. Natives of Central America.

P. elata.—Robust, bulbs 6 ins. high, erect spike 3–6 ft., flowers waxy-white.

Phaiocalanthe. — Garden-raised hybrids between the genera Phaius and Calanthe.

Phaius.—Bulbs short, stout, on thick rhizomes. Leaves tall, plicate, spike erect, flowers large, lip spurred at its base.

P. bicolor.—Bulbs small, flowers reddish-brown, lip white and rose; summer.

P. Blumei.—Spike 3–4 ft. high, flowers buff-yellow, mottled with red, front of lip crimson; spring.

P. flavus.—Bulbs 3–5 ins. high, flowers ochre-yellow; summer.

P. Humblotii.—Spike 18–30 ins. high, flowers light rose-purple; spring.

P. maculatus.—Leaves spotted, flowers buff-yellow, lip reddish; spring.

P. tuberculosus.—Bulbs stem-like, flowers white, lip rose; winter.

P. Wallichii.—Spike 3–5 ft., flowers tawny-buff, shaded red, lip white with yellow base; late winter.

Phalænopsis.—Distinguished by absence of bulbs, the plants having large, broad, usually leathery leaves. Roots flat and clinging, often of considerable length. Distributed throughout the Eastern Tropics.

P. amabilis.—Leaves green, flowers 3–5 ins. across, segments broad, pure white; winter.

P. Aphrodite.—Somewhat similar to *P. amabilis*, but more compact, lip broader; winter.

P. esmeralda.—Erect spikes of amethyst-purple flowers about an inch across; late summer.

P. Lowii.—Dwarf, leaves green, flowers 1½–2 ins. across, white, lip purple; summer.

P. rosea.—Leaves green, flowers 1½ ins. across, white flushed with rose-purple.

P. Sanderiana.—Flowers large, rose-pink, lip white marked with rose-purple; late autumn.

P. Schilleriana.—Leaves marbled, green and grey, spike 2–4 ft., flowers light rose-purple, sepals speckled; spring.

P. Stuartiana.—Leaves mottled, flowers white, lightly spotted; winter.

P. violacea.—Leaves bright green, flowers 2–3 ins. across, white shaded with violet-purple; summer.

Platyclinis.—Bulbs small, bearing a single, stalked leaf, and producing from the apex a slender, many-flowered spike. Natives of the Philippines.

P. filiformis.—Bulbs 1 in. high, flower stalk very slender, canary-yellow; summer.

P. glumacea.—Bulbs 2 ins. high, flowers yellowish-white, scented; spring.

Pleione.—Distinguished from Cœlogyne by the bulbs being of annual duration only. Leaves deciduous, usually falling after the bulbs are matured.

P. humilis.—Flowers 2–3 ins. across, blush-white, lip purple spotted; winter.

P. lagenaria.—Flowers rose-lilac, lip white, marked with crimson; winter.

P. maculata.—Flowers white, lip marked with crimson; autumn.

P. præcox.—Flowers 3 ins. across, rose-purple; early winter.

Pleurothallis.—Epiphytal plants of tufted habit, or stems borne at intervals on a creeping rhizome. Flower spikes produced from base of leaf, in many instances for several successive years.

P. Grobyi.—Flowers small, yellow streaked with crimson; various. Height, 3–4 ins.

P. Rœzlii.—Spikes nodding, flowers blackish-purple; spring. Height, 12–15 ins.

Renanthera.—Allied to VANDA, clothed with distichous leaves, and bearing panicles of showy flowers on lateral peduncles.

R. coccinea.—Stem tall, flowers 3–4 ins. across, blood-red, lip small, yellow and red; various.

R. Imschootiana.—Dwarf, flowers many, bright vermilion; spring.

Restrepia.—Somewhat similar in habit to PLEUROTHALLIS. Flowers produced singly on slender peduncles. Upper sepals and petals thread-like, lower sepals much larger. Natives of cool districts in Colombia, etc.

R. antennifera.—Flowers yellowish, marked with red; summer. Height, 4–6 ins.

R. maculata.—Flowers yellowish, densely spotted with brown-purple; summer.

R. striata.—Flowers yellowish, lower sepals striped with maroon; summer.

Rhyncostylis.—A small genus closely allied to SACCOLABIUM. Flowers in dense cylindrical racemes, produced from the axils of leaves; labellum a long, saccate, compressed spur.

R. cœlestis.—Leaves 4–6 ins. long, scape erect, flowers tipped with blue; summer.

R. retusa.—Leaves 8–12 ins. long, scape pendulous, 1–2 ft. long, flowers white, purple spotted; summer.

Saccolabium.—Stems furnished with leathery distichous leaves, from the axils of which the flowers are produced.

The basal portion of the lip developed into a saccate spur. Natives of India, Burma, etc.

S. bellinum.—Flowers yellow, marked with purple, lip spreading, fimbriated; spring. Height, 4–6 ins.

S. curvifolium.—Flowers cinnabar-red; summer. Height, 6–12 ins.

Sarcochilus.—A polymorphic genus, distributed from Burma to Australia and the Philippines. Flowers usually with a saccate lip, and often prettily coloured.

S. Fitzgeraldii.—Stems short, spike drooping, flowers 1 in. across, spotted with rose-purple; summer.

S. Hartmanni.—Stems short, leaves fleshy, flowers white, marked with red; spring.

Schomburgkia. — Robust plants, allied to LÆLIA, bulbs somewhat cylindrical, leaves leathery. Flowers produced at apex of long, arching spikes.

S. crispa.—Bulbs 4–8 ins. high, spike 2–4 ft., flowers crisped, brown and yellow, lip whitish; winter.

S. Lyonsii.—Bulbs 6–12 ins. high, spike 3–4 ft., flowers white, marked with purple; summer.

S. tibicinis.—Bulbs 9–18 ins. high, spike 3–5 ft., flowers reddish-brown; early summer.

S. undulata.—Bulbs 9–12 ins. high, spike 2–4 ft., flowers purplish-brown; spring.

Scuticaria.—Characterised by fleshy stems and long sub-terete leaves, which are pendent. Short scapes produced from side of stem.

S. Hadwenii.—Leaves 9–18 ins. long, flowers 3 ins. wide, yellowish-green, blotched with brown; summer.

S. Steelii.—Leaves 2–4 ft. long, flowers 3 ins. wide, light yellow, marked with reddish-brown; summer.

Selenipedium.—South American representatives of the genus Cypripedium. Leaves leathery, strap-shaped. Scape producing a succession of flowers, only one or two being open at the same period.

S. caudatum.—Flowers large, petals ribbon-like, often 30 ins. long; early summer.

S. longifolium.—Leaves 2 ft. long, dorsal sepal green, with rosy veins, petals twisted; various.

Sobralia. — Evergreen, terrestrial plants, chiefly of Central America. Stems reed-like, tall, furnished with sheathing leaves. Flowers large, produced from apex of stem.

S. macrantha.—Stems 4–8 ft. high, flowers crimson-purple, lip broad; summer.

S. rosea.—Stems 3–6 ft., flowers rosy-mauve, lip crimson-rose; summer.

S. Ruckeri.—Stems 4–6 ft. high, flowers rose-flushed, lip lilac-rose; summer.

S. Sanderiana.—Stems 4–8 ft., flowers rose-tinted, lip crimson-purple; summer.

S. xantholeuca.—Stems 3–8 ft., flowers creamy-yellow, lip darker; summer.

Sophrocattleya.—Garden-raised hybrids between the genera Sophronitis and Cattleya.

Sophrolælia.—Garden-raised hybrids between the genera Sophronitis and Lælia.

Sophrolæliocattleya. — Garden-raised hybrids between Sophronitis, Lælia, and Cattleya.

Sophronitis. — Epiphytal plants of dwarf habit, the small bulbs having a single, leathery leaf. Natives of Brazil.

S. grandiflora.—Flowers comparatively large, brilliant scarlet; winter.

S. violacea. — Rhizome creeping, flowers violet-magenta; winter.

Spathoglottis. — Terrestrial, distributed throughout the East, from Burma to China. Rhizomes creeping, with small, corm-like bulbs, and tall, plicate, grass-like foliage.

S. aurea.—Leaves 2–3 ft., flowers 3 ins. wide, yellow; autumn.

S. Fortunei.—Leaves 9–18 ins. high, flowers 1–1½ ins. wide, yellow; autumn.

S. plicata.—Leaves 2–3 ft. high, flowers 1–2 ins. wide, rose-purple; summer.

S. Vieillardii.—Leaves 2–3½ ft. high, flowers 2 ins. wide, rose-white; autumn.

Stanhopea. — Epiphytal plants, natives of Central and South America, and producing large, handsome flowers, the lip of which is of remarkable construction and wax-like substance. Bulbs usually ovoid, with a single, broad leaf; spikes pendulous.

S. eburnea.—Flowers fragrant, ivory-white; summer.

S. oculata.—Flowers large, yellowish, with red spots; summer.

S. tigrina.—Flowers large, yellow and blood-red; summer.

S. Wardii.—Flowers large, fragrant, golden-yellow, spotted with red-purple; summer.

Thunia.—A small genus of tropical plants, having leafy, tapering stems, which produce nodding racemes of flowers.

T. alba.—Stems 2–4 ft. high, flowers white, lip fringed ; summer.

T. Bensoniæ.—Stems 2 ft. high, flowers amethyst-purple ; summer.

T. Marshalliæ.—Stems 2–3 ft. high, flowers white ; summer.

Trichopilia.—Epiphytal plants distributed throughout Central America. Bulbs usually flattish, with a single, leathery leaf. Spikes of large flowers produced from base of bulb.

T. crispa.—Spikes two to three flowered, crimson, margin crisped ; early summer.

T. fragrans.—Spike erect, flowers greenish-white, lip spreading ; autumn.

T. laxa.—Flowers dull rose, lip whitish ; various.

T. suavis.—Flowers large, cream-white, rose spotted ; spring.

T. tortilis.—Flowers with narrow twisted segments, rose, lip blotched with red-brown ; various.

Vanda.—Handsome epiphytal plants distributed throughout the warmer countries of the East. Stems erect, clothed with distichous, evergreen leaves. Flowers produced on scapes from the axils of the leaves.

V. Amesiana.—Stems short, flowers fragrant, white, lip deep rose.

V. coerulea.—Stems 1–3 ft. high, flowers large, sky-blue, lip small ; autumn.

V. Hookeriana.—Stems 2–5 ft. high, leaves slender, cylindrical, flowers whitish, purple flushed ; autumn.

V. Kimballiana. — Leaves 6–9 ins. long, flowers white, purple flushed ; autumn. Height about 1 ft.

V. lamellata.—Dwarf habit, leaves 12–15 ins. long, flowers yellow, blotched with brown ; winter.

V. Parishii.—Stems short, leaves 6–9 ins. long, flowers greenish-yellow, marked with brown, lip purple ; summer.

V. Sanderiana.—Flowers 5 ins. across, rose, marked with reddish spots and veins, lip small. Very handsome ; late summer.

V. suavis.—Leaves 12–18 ins. long, flowers white, purple spotted, lip rose-purple ; various. Height, 2–5 ft.

V. teres.—Stems and leaves terete, flowers rose-white to magenta-rose ; spring.

V. tricolor.—Leaves 12–18 ins. long, flowers yellowish-white, with reddish-brown marks ; various. Height, 2–5 ft.

Vanda Hybrids. — Two elegant hybrids artificially raised are *Marguerite Maron* (suavis × teres) and *Miss Joaquim* (Hookeriana × teres).

Vanilla. — Climbing or scandent plants, usually with fleshy leaves, and with large flowers. The elongated capsules yield the well-known flavouring material.

Vuylstekeara. — Garden-raised hybrids between the genera Cochlioda, Miltonia, and Odontoglossum.

Wilsonara.—Garden-raised hybrids between the genera Cochlioda, Odontoglossum, and Oncidium.

Zygocolax.—Garden-raised hybrids between Colax and Zygopetalum.

Zygonisia.—Garden-raised hybrids between Aganisia and Zygopetalum.

Zygopetalum.—A large, polymorphic genus, epiphytal, and distributed chiefly through Central America.

Z. crinitum.—Bulbs 2–3 ins. high, leaves 1–2 ft., flowers green and brown, lip white, with densely haired violet-blue veins ; winter.

Z. intermedium.—Somewhat similar to *Z. crinitum*, but lip slightly downy ; autumn.

Z. Mackayi.—Differs from *Z. intermedium* by its perfectly hairless lip ; autumn.

Z. maxillare.—Bulbs 2–3 ins., at intervals on creeping rhizome, lip violet-blue, with fleshy crest ; various.

Z. rostratum.—Bulbs 2–3 ins. high, at intervals on creeping rhizome, flowers greenish, lip white ; summer.

G. W.

ORCHIDS : HARDY. — See *HARDY ORCHIDS.*

ORCHIDS : POTTING AND WATERING OF. The cultivation of Orchids forms an important branch of the gardener's art, and next to the provision of the necessary houses, with suitable climatic conditions, comes the question of potting and watering of the plants. The latter includes the important process of damping down, by which the necessary amount of atmospheric moisture is provided, and this in turn depends largely upon the outside conditions and the amount of artificial heat that has to be given.

Potting.—Orchids fall naturally into two great classes, *terrestrial* and *epiphytic*, the cultivation of the former presenting no more difficulty than that of an ordinary stove or greenhouse plant. The roots of a plant serve the double purpose of obtaining a secure anchorage to the soil and of absorbing the food materials, by means of the absorbent root hairs. In terrestrial Orchids the roots are either of the

usual fibrous nature or are thick and fleshy, with numerous root hairs, the latter class chiefly thriving where there is a large mixture of humus in the soil. Epiphytes are more or less adapted to an aerial mode of existence, and many of them grow naturally up in the trees, where the conditions are very different from those of the forest floor. This position is mainly determined by the necessity of obtaining an adequate amount of light, but it entails modifications of root structure which renders special cultural conditions necessary. Terrestrial Orchids are mainly natives of woodlands, of more or less shaded rocks, or of open prairies and marshes. There is a kind of intermediate class, sometimes called *pseudo-epiphytes*, the members of which grow chiefly among accumulations of humus in forks of the branches of the trees, and these, as regards their cultural requirements, are practically humus-loving terrestrials.

True epiphytes are mainly known by a modification of root structure, this taking the form of a white, papery covering to the thickened aerial roots, this covering—known technically as the *velamen*—being partly protective and partly absorbent of atmospheric moisture. Aerial roots generally attach themselves to the bark of the branches of the trees, and besides absorbing the necessary nutriment, also provide a secure anchorage for the plant. In culture they frequently attach themselves to the sides of the pots or baskets. An important cultural point is that when the roots are actively growing, a green point protrudes from the apex, which becomes what is termed "sealed over" when the plants are at rest. Epiphytic Orchids are generally grown in wood baskets or shallow pans—occasionally on branches of trees with a little fibre wired on—and suspended from the roof of the house at a suitable distance from the glass. The larger kinds should be grown in ordinary pots and stood on the stages.

The best time for potting is just when the young roots are beginning to push out as the plants resume their season's growth; they are then able to avail themselves of the new compost. The chief exception to this rule is where the plants flower just when the young growths and roots are appearing, in which case delay is permissible until the flowers are over, but extra care must be taken that the young roots are not broken during the process. There is no fixed time for potting, as different Orchids start into growth at quite different periods, and this is a great convenience where large numbers are grown.

Composts depend largely upon the class of Orchid being dealt with, and different growers often have their own special mixtures. For such widely grown Orchids as Masdevallias, Miltonias, Odontoglossums, and Oncidiums, however, a mixture of good peat, A1 fibre,[1] and sphagnum moss in equal parts is suitable. For the whole of the Cattleya group use clean A1 fibre with a liberal admixture of sphagnum moss. Peat or osmunda fibre may also be added, the chief thing being that the fibre is clean, porous, and consequently not too retentive of moisture. Angræcums, Phalænopsis, and Vandas succeed in a similar compost, with rather more sphagnum added. For Dendrobiums and similar plants use three parts of A1 or osmunda fibre with one part sphagnum. For such terrestrial Orchids as Calanthes, Lycastes, Phaius, Zygopetalums, and the green-leaved Cypripediums, a mixture of peat, A1 fibre, and loam fibre, with an admixture of sphagnum, some broken leaves, and a little sharp sand and finely broken crocks to keep it open, is suitable. The tessellated-leaved Cypripediums succeed best when the loam is left out. Most other Orchids can be referred to one or other of these classes.

Use clean, well-drained pots, with a little of the roughest of the compost over the drainage to keep it open. Any dead roots or old pieces of the rhizome should be cut away, after which insert the plant in position, and add the compost gradually, making it firm with a potting stick. Firm potting is important, and a stake should be added whenever necessary. Epiphytic Orchids should have the base of the plant about level with the rim of the pot, but terrestrial kinds should be put rather lower, so as to leave more room for watering. The compost should be only slightly moist when used, after which very slight watering is required until the new roots have taken hold of it.

[1] A1 fibre is not a proprietary article, as every Orchid grower will be aware.—EDITOR.

Watering. — This depends largely upon the season of the year, and whether the plant is in active growth or at rest. After potting, the roots generally take hold of the new compost quickly, and the plants then begin to grow strongly, when they will require an ample supply of water. Care should be taken not to give water until the compost has become moderately dry, as this helps to keep it from becoming sour; on the other hand, no plants must suffer from want of water at this stage. When water is required give a good soaking, and any surplus will drain away at once. As soon as growth is completed, the supply of water at the root should be gradually reduced until the plant is at rest, when only sufficient will be required to keep the compost just moist.

The requirements of different groups differ greatly, and no absolute rules can be given. In a general way it may be said that deciduous or semi-deciduous species, and those with very fleshy leaves, require moderate drying when at rest, while at the other extreme are species which are never quite at rest, and for these the compost should be kept just moist in the winter. Species having pseudo-bulbs can generally be kept drier when at rest than those without them. Perfect drainage and a well-aerated compost are essential in the case of all epiphytic Orchids, as this approximates to their condition in a state of nature. Stagnant water hastens the decay of the compost, and a sour compost in turn leads to the loss of roots and a consequent reduction in the food supply of the plant.

The question of atmospheric moisture is a very important one in Orchid culture, particularly in hot weather, and this is provided for by damping down the floors and stages of the house as necessary, and on hot afternoons by a light syringing of the pots and surface of the compost, care being taken not to lodge water in the young growths, which may result in their decay. On wet, sunless days less damping down is necessary, since the air is naturally moist; also the plants need much less when at rest, especially during the winter months. During the latter period the use of much fire heat to maintain the necessary temperatures results in a drying of the atmosphere, and this is corrected by an increase in the amount of damping down. Judgment is necessary, the time of year and the condition of the plants being taken into consideration, but experienced growers on entering the house can tell by the feeling of the atmosphere whether the conditions are right.

R. A. R.

ORCHIS.—For the best species see *HARDY ORCHIDS.*

OREGON CRAB APPLE (*Pyrus rivularis*).—See *TREES.*

ORGANIC MANURES.—See *MANURING: PRINCIPLES OF.*

ORGANIC MATTER.—See *CHEMISTRY FOR GARDENERS* and *MANURING: PRINCIPLES OF.*

ORGANIC PRODUCTS.—See NITROGENOUS MANURES in *MANURES.*

ORGANISATIONS.—See *ALLOTMENT ORGANISATIONS.*

ORGYRIA.—See VAPOURER MOTH in *INSECT PESTS.*

ORIENTAL PLANE (*Platanus orientalis*).—See *TREES.*

ORIENTAL POPPIES (*Papaver orientale*).—See *POPPIES: PERENNIAL BORDER SPECIES.*

ORIENTAL SPRUCE (*Picea orientalis*).—See *TREES.*

ORIGANUM (MARJORAM. Nat. Ord. Labiatæ). — A few of the many species of this genus are worthy of including in the herbaceous border apart from such herbs as SWEET MARJORAM (*O. Majorana*); POT MARJORAM (*O. Onites*); and WILD or COMMON MARJORAM (*O. vulgare*). See article on *POTHERBS.* One of these desirable species, *O. Dictamnus,* popularly known as DITTANY OF CRETE, is an attractive pink, July blooming border plant about 12 ins. high. Another, *O. hybridum,* is useful in the rock garden, and bears its little pink flowers from June to August on plants 6–9 ins. high. A third, *O. pulchrum,* is also pink, and similar to *O. hybridum,* but it may attain a height of 12 ins. All thrive under the treatment usually given to rock plants and the dwarfer perennials if grown in light soil, and may be propagated by cuttings,

division of the roots, and seeds, at the usual times in the spring and summer.

ORLAYA.—Now included in the genus *DAUCUS*.

ORMENSIS.—Now included in the genus *ANTHEMIS*.

ORNAMENTAL GOURDS.

Apart from the edible gourds and pumpkins (see notes on *PUMPKINS AND GOURDS*) there are a large number of kinds which are exceedingly curious and ornamental. The majority are easily grown, and if given the ordinary treatment for vegetable marrows will succeed admirably. The best way, however, is to treat them as half-hardy annuals, sowing early in heat, and either potting on or pricking off as soon as large enough to handle, subsequently planting them out when all danger of frost is past, so that they can ramble over arbours, trellis work, rockeries, or rooteries. Beauty spots can easily be made if these are planted in ugly corners, and heaps of rotting vegetable refuse might easily be beautified by planting these on them.

The best ornamental sorts are: BISHOP'S MITRE GOURD, BOTTLE GOURD, HEDGEHOG GOURD, HERCULES' CLUB, LOOFAH, MAMMOTH GOURD, NAPLES GOURD, NUTMEG GOURD, OHIO SQUASH, OSTRICH EGG, POWDER FLASK, RED TURK'S CAP, SCARLET GOURD, SNAKE CUCUMBER, SQUIRTING CUCUMBER, SYPHON GOURD, TEASEL GOURD, WARTED GOURD, WAX GOURD, WHITE TURK'S CAP, and YELLOW HUNDREDWEIGHT. Seeds of these can be obtained from all first-class seedsmen.

ORNAMENTAL GRASSES.

Considering their undoubted value, and the ease with which they may be grown, it is strange that ornamental grasses are not more frequently seen in gardens. They are admittedly decorative in flower borders, and everyone who has had the care of cut flowers for vase decoration will know how easy it is to get a pretty effect if only a few light sprays of grasses are available, and yet it is just these latter that are generally lacking. It surely must be that they are overlooked at sowing time. In the green state, grasses are a very agreeable change from the usual Gypsophila in the making up of bouquets, and they are available for a longer period, while for adding grace to winter posies of "Everlasting" flowers and highly-coloured berries, they are, of course, indispensable. For this latter purpose the grasses should be cut as soon as the flower heads are fully expanded, tied in small bunches, and hung upside down to dry in an airy position.

The greater number of the best sorts are hardy annuals, and thrive with the minimum of care which is generally allotted to annual flowers, but whether it is grasses or flowers a good return is always got by sowing thinly and allowing ample space for development. It will be found necessary, in most cases, to pull the seed-heads into small pieces for convenience of sowing. All the varieties may be grown in vacant spaces in the flower border, but they are well worth a small plot reserved exclusively for them. The perennial sorts may be sown any time from March till June, and being much slower in growth, they require more care than the annuals. It is well to sow them thinly on a well-prepared seed-bed, transplanting as soon as large enough, and putting into flowering positions in the autumn. All grow freely in ordinary garden soil.

Some of the dwarf-growing sorts, such as *Lamarkia aurea* and HARE'S-

TAIL GRASS (*Lagurus ovatus*), make a very neat and effective edging for summer beds, while the perennial FEATHER GRASS (*Stipa pennata*), with its long drooping plumes, is available where a permanent bordering is desired.

Some Good Varieties.—The following notes include only the most desirable sorts of easy cultivation. All are annuals unless otherwise stated :—

Agrostis nebulosa (CLOUD GRASS). —Very light and graceful, the fully developed panicles resembling a mist-like veil. One of the most useful for small vases. It grows about 18 ins. high.

Agrostis laxiflora is somewhat similar to the preceding, but has longer branches to the seed-head.

Agrostis pulchella is a miniature form, growing 4–6 ins. high, but has the same elegant inflorescence. It is well adapted for edgings and for pots in the cold greenhouse.

Avena sterilis (ANIMATED or WILD OATS). — This is a strong-growing grass about 2 ft. high, with large drooping spikelets. There are pale-seeded and dark-seeded forms, and the latter are generally considered the more decorative.

Briza gracilis (LITTLE QUAKING GRASS).—This is a miniature form of the native Quaking Grass of our upland pastures. It is an exceedingly pretty little species, with pale green nodding spikelets on hair-like branches. Height, 9 ins.

Briza maxima is the GIANT QUAKING GRASS or PEARL GRASS, and well worth growing for its bold effect and large seed-heads. Height, 18 ins.

Bromus brizaeformis.—An elegant biennial grass, similar in habit to *Briza maxima*, but the spikelets are longer and narrower. Very decorative in the mixed border. Height, 1½–2 ft.

Coix Lachryma-Jobi (JOB'S TEARS). — A half-hardy species, which requires to be sown in February or March and planted out. In warm districts the seeds may be sown in April or May. The plant attains a height of 2 ft., and is unique in appearance on account of its peculiar large, greyish, round seeds, which hang in clusters from their sheaths, and from which the popular name is derived.

Eragrostis elegans (LOVE GRASS). —A large, spreading, loose-headed grass, particularly valuable for bouquets and large vases. Height, 2 ft.

Gynerium argenteum (PAMPAS GRASS).—One of the noblest and best known of all ornamental grasses. Its huge plumes are particularly striking in the autumn months. The plant is perennial, withstands the severest winters, and its long, handsome, curving foliage is attractive at all seasons of the year. There are some varieties with pinkish and creamy plumes, and a batch of seedlings will generally give such variations. Height, 5–8 ft.

Hordeum maritimum (SQUIRREL-TAIL GRASS).—One of the best types of the Barley Grasses. It has very long, hairy, gracefully curved spikes, and grows about 2 ft. high. For winter use this grass should be gathered just after the spike has emerged from the sheath, as the seed-heads are liable to break in sections if allowed to become too ripe.

Lagurus ovatus (HARE'S-TAIL GRASS).—A very handsome grass with large, oval, downy heads, which suggest its common name. It is found wild in some parts of the country, and grows about a foot high. This is one of the favourite varieties, and some fine specimens may be obtained if sown during the autumn in a sheltered position, and planted out in the spring.

Lamarkia aurea has no recognised common name, but it is a well-known and pretty dwarf species, quite worthy of a place in all collections of Ornamental Grasses. Height, 6 ins.

Pennisetum longistylum (PLUME GRASS). — A downy-headed grass somewhat resembling the Hare's-tail, but the heads are much longer, sometimes growing to a length of 6 ins. This elegant species is not so hardy as some others, and will well repay sowing in slight heat and planting out. It grows about half a yard in height.

Stipa pennata (FEATHER GRASS). —A most desirable perennial, with long, slender, drooping plumes which reach nearly to the ground; extremely ornamental. Height, 18 ins.

Zea Mays variegata (VARIEGATED MAIZE).—This also belongs to the natural order of grasses, but will be found dealt with elsewhere.

S. & S.

ORNAMENTAL VEGETABLES.

In these brief notes will be enumerated a few species and varieties of vegetables noted for their decorative value in addition to their culinary worth. Such are given as a guide for those who, for any reason, wish to grow, or perforce must grow, vegetables near the house, and would like to know of those possessing some claim to ornamental or distinctive leafage.

First of all we must mention that greatly prized, early, succulent vegetable, *Asparagus*. For five or six months of the year its feathery sprays wave to and fro in the breeze, first green, then yellow, with its seeds of scarlet berries. Its presence in markets among cut flowers is well known. Then the *Globe Artichoke* is a handsome plant with greyish-toned, divided foliage, and, like Asparagus, can be planted to remain a number of years, if the position chosen be warm and sheltered. Its edible portion of scaly-globe heads is both interesting and attractive.

Beetroot is, perhaps, the best known of ornamental vegetables, and, in addition to usage in beds and borders, can be interplaced singly or grouped among other subjects. Preference should be given to the black-leaved variety as being the most striking. The finely cut fern-resembling tops of *Carrots*, we may mention, might more often be used in floral work, thus placing this root high among those of ornate importance. Beds of Carrots retain a neat appearance throughout the season. Well-grown *Endive* is also most pleasing, the curly-leaved sorts particularly evoking admiration.

Extremely picturesque are the *Kales* (Borecole or May Greens) with their curly and incised leaves. All Kales are more or less attractive, but for being the most distinct we may vote the Russian variety to first place; its leaves in a rather remarkable degree resemble deer's antlers. *Kohl Rabi* must claim a place on account of its most peculiar, albeit neat, growth. In addition to the usual central leaves, others spring out singly at different parts of the Turnip-like root, for which vegetable it makes a good substitute. We may mention that the purple variety is the more attractive. An old favourite comes next, namely, *Lettuce*. The cabbage type is the best for the purpose now in view. Nicely rounded heads of these are prim and pleasant to look upon, but special praise must be accorded the brown-tinged *Continuity*, which is very distinct, also to the beautiful Endive-leaved and Fringe-leaved varieties. *Maize* (Indian Sugar Corn or Sweet Corn) is another attractive and ornamental crop, with its up-

right and stately foliage, the cobs of corn having a frizzy tassel on each top. Long famed in Canada, it is getting more recognised, and rightly so, in English gardens.

Parsley is, perhaps, more strictly a herb, but because of its abundant and wide usage we class it here among ornamental vegetables. Large breadths of its rich green always look inviting, but it is as an edging plant it excels. For elegance of form choose the Crested and Fern-leaved sorts. [Many of the *Pot-herbs* and *Medicinal Herbs* are distinctly ornamental, and the reader should refer to the two articles on these.—Editor.]

The last three to be here dealt with are *Scarlet Runners*, *Tomatoes*, and *Vegetable Marrows*. Each requires some support to show its best in floral effect and utility. The bright scarlet blossoms of the Runners, and later the hanging clusters of Beans, are familiar sights clambering up poles and fences. Then we have the extensively grown Tomato. The blossoms, true, are rather insignificant, but the bunches of fruit ever in the green state are, at least, an agreeable sight. But what shall we say of the scarlet clusters hanging on plant after plant? It is no exaggeration to call them beautiful.

Lastly, we may mention the humble Vegetable Marrow, which indeed makes a gratifying picture if trained up rough trellis-work, or allowed to ramble its own way over banks or mounds of turf and rubbish. It will cover many an unsightly spot with its verdant foliage lit up by its dazzling golden-yellow flowers, with here and there a huge dark green fruit. One cannot help wondering why this crop is not more grown by the gardener who wishes to combine utility with beauty.—C. T.

ORNAMENTAL WALLS.—These are referred to in the editorial note in *Garden Walls*.

ORNITHOGALUM.— See *Star of Bethlehem*.

ORNITHOPUS (Bird's-foot. Nat. Ord. Leguminosæ).—This is a genus of weedy, hardy annuals of no garden value. *O. perpusillus* is the Common Bird's-foot, and *O. sativus* is the weed known as Serradella. They bear yellow flowers from June to July, and average 6 ins. in height.

OROBUS.—Now included in the genus *Lathyrus*.

ORPINE (*Sedum Telephium*).— See *Sedum*.

ORRIS ROOT.—See *Medicinal Herbs*.

ORTHOPHOSPHATES.—See Calcium Orthophosphates in *Lime Compounds*.

ORTHOPHOSPHORIC ACID.— See Phosphoric Acid in *Acids: Their Uses in Horticulture*.

OSIER (*Salix viminalis*).—See *Trees*.

OSMANTHUS.—For the best species see *Climbing and Trailing Plants*.

OSMOSIS.—See *Plant Physiology*.

OSMUNDA.—For the best species and varieties see *Ferns and Fern Gardening*.

OSO BERRY (*Nuttalia cerasiformis*). See *Shrubs*.

OSTEOMELES.—For the best species see *Shrubs*.

OSTRICH EGG.—A name applied to a decorative gourd. See *Ornamental Gourds*.

OSTRICH FERN (*Onoclea germanica*). See *Ferns and Fern Gardening*.

OSTROWSKIA (Nat. Ord. Campanulaceæ).—One species of this genus, *O. magnifica*, is a magnificent, hardy, herbaceous perennial, but a rather shy bloomer except in warm districts. It dislikes a dry and ultra-sunny spot, but otherwise is easy to grow, and may be propagated without any difficulty by root division in March. It bears

pale blue flowers from June to July, and grows 3–5 ft. in height.

OSTRYA.—For the best species see *TREES.*

OSWEGO TEA (*Monarda didyma*).—See *MONARDA.*

OTHOCALLIS.—Now included in the genus *SCILLA.*

OTIORHYNCHUS.—See OTIORHYNCHUS WEEVILS and RASPBERRY WEEVIL in *INSECT PESTS.*

OTIORHYNCHUS WEEVILS. — See *INSECT PESTS.*

OUTDOOR CHRYSANTHEMUMS.—See *CHRYSANTHEMUMS : CULTIVATION OF.*

OUTDOOR CUCUMBERS. — See *CUCUMBERS : OUTDOOR.*

OUTDOOR TULIP CULTURE.—See *TULIPS.*

OVAL-LEAVED PRIVET (*Ligustrum ovalifolium*).—See *SHRUBS.*

OVARY.—See under LIFE HISTORY OF FLOWERING PLANTS in *PLANT PHYSIOLOGY.*

OVERCUP OAK (*Quercus lyrata*). — See *TREES.*

OX-EYE DAISY (*Chrysanthemum Leucanthemum* and *C. maximum*).—See *CHRYSANTHEMUM : PERENNIAL BORDER SPECIES.*

OXALIC ACID.—See *PLANT PHYSIOLOGY.*

OXALIS (WOOD SORREL. Nat. Ord. Geraniaceæ). — This is a very large genus of hardy annuals, hardy herbaceous, or hardy perennials, doubtfully hardy or distinctly half-hardy bulbs, greenhouse herbaceous perennials and bulbs, half-hardy or stove evergreens, and hardy or half-hardy rock plants. It is impossible to describe species under each of these sections, but the most important are mentioned below.

Annual Species.—These require none but the usual treatment bestowed on hardy annuals, and are of very easy culture. The best species is :—

Oxalis corniculata.—This bears yellow flowers from August onwards, and averages 3 ins. high. Its variety *atropurpurea* has dark purple leaves, and *rubra* has darker leaves still.

Bulbous Species.—Most of these are not very hardy, and are most successful if given pot culture. They are not specially beautiful, though useful in the spring and autumn for greenhouse decoration. For outdoor culture a warm site and a light soil is required, and propagation by bulbils is the best way of increasing one's stock. Of the large number of species we recommend the following :—

Oxalis Bowiei.—Syn. *O. purpurata,* which see.

O. cernua (BERMUDA BUTTERCUP or BUTTERCUP OXALIS).—This bears umbels of bright yellow flowers in April, and grows 1 ft. high.

O. hirta (Syn. *O. rubella*).—This and its varieties bear lilac to crimson flowers in October, and grow 3–9 ins. high.

O. purpurata (Syn. *O. Bowiei*).—This, known by some as the CAPE SHAMROCK, bears bright rose flowers from August to September, and averages 6 ins. in height.

O. rubella.—Syn. *O. hirta,* which see.

O. tetraphylla.—This bears lilac flowers, sometimes inclining to rose, from June to July, and averages 6–9 ins. high.

O. versicolor.—This bears white flowers, which are red outside, in March and April on plants about 3 ins. high.—J. J. & E. T. E.

Greenhouse Species. — All the bulbous species just named are suitable for pot culture in the greenhouse, but should be kept dry in the winter. The following herbaceous kinds are also suitable for greenhouse culture, and should be kept moderately dry from November to March. These are best propa-

gated by seeds and root divisions in the usual way, and grown in a mixture of good loam, peat, and sand. Temperature required for all grown in greenhouse culture, 40–45° F.

Oxalis floribunda.—Rosy-red, pure red, pure white, blush and lilac varieties of this blooming in March are grown at Kew. Height, 6 ins.

O.rosea.—Rose. Flowers in March. Height, 6 ins.

O. tuberosa.—Pink. Flowers in November. Height, 5 ins.

Perennial Border Species.—Only one is at all suitable, and this spreads rather rapidly. It requires none but the usual treatment given to hardy perennials, thrives in common garden soil, and is propagated by seed and division in the usual way.

Oxalis Acetosella (COMMON WOOD SORREL or WOOD SORREL).—This bears white flowers from May onwards, and grows 3 ins. high.

Rock Garden Species.—These are easily grown plants, generally with a tuberous or fleshy rootstock. They will thrive well in warm districts, and are best propagated by division of the roots in the autumn or spring. The three best are :—

Oxalis adenophylla. — This has greyish leaves in tufts from a tuberous rootstock. Flowers pink, with dark eye. Site, half-shade. Soil deep, gritty loam. Flowering Period, May to July. Height, 4 ins.

O. enneaphylla (NINE-LEAVED WOOD SORREL).—This has greyish leaves in tufts from fleshy rootstocks. Flowers usually white, though a rosy form is in cultivation. Site, half-shade. Soil deep, gritty loam. Flowering Period, May to July. Height, 4 ins.

O. lobata.—This has green foliage in tufts from tuberous roots. Flowers yellow. Site, half-shade. Soil gritty loam. Flowering Period, October. Height, 3 ins.

[An edible species, *O. Deppei*, is grown and used as a vegetable on the Continent, but is relatively unimportant here, and so its culture need not be described.—EDITOR.]

OXYCOCCUS.—For the best species see *SHRUBS.*

OXYGEN.—A few notes on this element are given in our article on *CHEMISTRY FOR GARDENERS.*

OXYRIA.—See *MOUNTAIN SORREL.*

OXYTENANTHERA.—See *BAMBOOS.*

OXYTROPIS (Nat. Ord. Leguminosæ).—This is a genus of comparatively little known but attractive, hardy, herbaceous perennials for rockwork, for edgings to borders, and for other similar purposes. They thrive with remarkable freedom in some rock borders where plenty of stone is used. For ordinary culture, a dry, sunny site and light soil are required. Propagation may be best effected by seeds or cuttings. The best time to plant is early in March. Of the numerous species that have been described most are purple. *O. montana* is yellowish-purple, *O. ochroleuca* is cream, *O. splendens* is rosy-red, and *O. uralensis* (Syn. *O. Halleri*) is purple. They bloom from April to July, and average 3–6 ins. high. For fuller descriptions larger works must be consulted.

NEW VARIETY.

Oxytropis hybrida grandiflora alba.—This has white flowers, with a dark spot on the keel.

OYSTER PLANT (*Mertensia maritima*). See *MERTENSIA.* The name is also applied to *SALSAFY.*

OYSTER SHELL BARK SCALE.—See *INSECT PESTS.*

OYSTER SHELLS.—See *FISH AS MANURE.*

OZOTHAMNUS.—For the best species see *CLIMBING AND TRAILING PLANTS.*

PACKING FLOWERS AND PLANTS.—It is often necessary to send flowers or plants by post, and the majority of gardeners are at a loss to know how to do this so that the subjects may arrive at their destination as fresh as possible. The following few hints will no doubt be useful in this direction.

Flowers.—In packing these, use a strong, covered-in wicker basket where possible, or a flat, wooden box. Cardboard boxes, even if very strong, are quite unsuitable, as they inevitably get badly damaged in going by rail or through the post. Spread a layer of strong but soft paper in the bottom and round the sides. Damp this thoroughly, and lay the flowers as flat as possible in layers, with the stems and heads alternately at each end of the box. Fill as full as possible, making up the centre part with soft paper to prevent the flowers shaking about; damp thoroughly once more, cover the whole with more of the paper, and fix the lid on firmly.

Another way is to pack the flowers in thin layers between damp moss. The box should be lined and the top covered with similar material. This is not very suitable for flowers it is desired to keep spotlessly white.

Where the flowers have to go a very long journey, it is well to pack them so that their stems all go to the centre of the box. A small wooden archway is then put over the stalks at each side, and the central part filled with wet sand. The rest of the box is packed tightly with soft, crumpled paper, to prevent shaking, and a very close-fitting lid is required to prevent the sand from getting out of its compartment into the rest of the box.

Cotton-wool and sawdust should never be used for packing flowers, as they absorb too much of their moisture.

Plants.—The packing of small plants and seedlings is a comparatively easy and simple process. Seedlings should be made up into a nice bunch, the roots being tied round with well-damped moss, and the entire bunch wrapped in newspaper. Then thick, corrugated cardboard should be wound round them, with circular bits cut to fit the ends, and then the package should be wrapped in strong brown paper, tied with strong string, and a tie-on label fixed upon it. Small clumps of hardy herbaceous plants may be wrapped individually in damped newspaper and tied up with bast. They can then be packed tightly together in a shallow wooden box or strong basket as for flowers. Large clumps are more awkward. A deep hamper or small packing-case is the best thing in which to send them. Where the roots are at all easily damaged, a liberal amount of damp moss should be packed round them. Between each layer of clumps, moist, fresh-cut grass may be used, but not hay, straw, or cotton-waste. If such is not available, then damp crumpled newspaper should be used. The hamper or packing-case should be filled as full as possible, and packed very tightly as, if the contents shake about, they may be considerably damaged. The lid of the hamper should be strengthened with strips of wood in case the railway company see fit to turn it upside down. The lid of the packing-case should be nailed down very securely.

Care should be taken in carriage

by rail to see that the package is correctly labelled with postal and rail address. In the case of parcel post the packages have to conform to the sizes and weights given in the Post Office Guide. Observance of such points as careful packing will avoid many unnecessary delays and disappointments.—E.

PACKING FRUIT.—See *FRUIT GRADING AND PACKING.*

PACKING PLANTS.—See *PACKING FLOWERS AND PLANTS.*

PADUA RUE (*Ruta patavina*).—See *RUTA.*

PAEONIA.—See *PAEONY* and *SHRUBS.*

PAEONY (Nat. Ord. Ranunculaceæ). Florists' section, hardy shrubs, 2–3 ft. high. They succeed in deeply worked, rich loam, well manured, preference being given to cow manure if procurable, and are propagated by seed and division of the roots. The former method, being slow, is hardly suitable for the amateur. Division is best done in summer after the flowering season. The *Tree Paeonies* are usually increased by grafting, the stock employed being *P. officinalis.*

Culture.—The European Paeonies bloom in May, and the Chinese varieties in June and July. Few flowers make such a prodigal display of colour, and at the same time give such little trouble. Given a good, rich soil, an annual mulch of manure in March, and protection from morning sun after frost, the plants will look after themselves, gaining in beauty each year till the soil shows signs of exhaustion. Then they should be taken up and given a change of quarters, or a thorough renovation of the old sites made before being replanted.

Varieties.—The named varieties are so numerous that it would be impossible to give a representative selection, each specialist having his own list and his own names. The *Tree Paeonies* are not quite so hardy as the herbaceous section. A sheltered border facing south-west is suitable, or they may be grown in pots for cool house decoration in spring.—J. L. G.

NEW VARIETIES.

Paeonia Lord Cavan.—This has single purplish-rose flowers, with a large centre of petaloid stamens.

P. Willmottiana.—This has pure white flowers, with crimson stamens tipped with yellow anthers. The flowers are often 6 ins. across, and are borne on plants 25–30 ins. high.

PAEONY-FLOWERED DAHLIAS.—See *DAHLIA : CULTURE OF.*

PÆSIA.—Now included in the genus PTERIS, for which see *FERNS AND FERN GARDENING.*

PAGODA TREE (*Sophora japonica*).—See *TREES.*

PAINT AND THE GARDEN.

There are two colours (if white can be called a colour) which are pre-eminently suitable for the garden—white and green—to these may be added chocolate, under certain conditions.

In painting new work, the wood should be first well primed with red and white lead priming, and afterwards painted three coats of white paint made from the best white lead, if white is required. A coat of lead colour should be given under green which has little body in it.

The stumps of fences should be tarred or creosoted, and the paint applied low down, an extra coat being given to all parts where much exposed to damp. When repainting old woodwork, any soil should be scraped away and the paint well washed. Greenhouses and painted woodwork under similar conditions should be well brushed, and if there are any traces of insect pests, disinfected before painting. The work

should be sandpapered, and any blisters removed if necessary with the blow-lamp. Holes and crevices must be filled with putty and rubbed smooth. Nothing but the best white lead and other pigments with pure linseed oil and turpentine should be used. Boiled oil is apt to blister in the sun, and should be used sparingly, although a little in green and chocolate paint is beneficial. A word about brushes may be added, namely, get the best brushes you can, and pay a good price for them, if you want to do the work well.—F. W. B.

PAINTED WOOD-LILY (*Trillium erythrocarpum*).—See *TRILLIUM*.

PAK-CHOI.—A synonymous name for *CHINESE CABBAGE*, which see.

PALIURUS.—For the best species see *SHRUBS*.

PALLADIA.—Now included in the genus *LYSIMACHIA*.

PALMS.

Under the popular name of Palms there are included many genera and considerably over a thousand species. They form a very important group of plants, both on account of their noble and ornamental appearance, and of their great importance from an economic point of view. The majority are natives of tropical countries, where many of them form large trees, as in the case of the ROYAL PALM (*Oreodoxa regia*), which has a straight, almost cylindrical trunk towering upwards until it reaches 150 ft. or more. Others again have slender stems only a few feet in height, an example being the elegant *Cocos Weddelliana*. Their economic properties are many; sago, sugar, wax, and oil are all obtained from them, and thus these plants play a large part in supplying our daily wants. The AFRICAN OIL PALM (*Elaeis guineensis*) may be cited as an instance. The oil extracted from the kernels is annually imported into this country to the value of several million pounds. It is used extensively in the manufacture of candles, margarine, and soap. In the various countries to which Palms belong, they supply the natives with practically all the necessaries of life, including food, which is obtained from the fruit, stems, and young leaves. Wine or "toddy" is also obtained in large quantities from the stems and inflorescences, the former are also employed in the building of houses, while the leaves are used as a thatch, and in the manufacture of baskets, brushes, hats, household utensils and ropes.

Palms are grown in this country solely for their valuable decorative qualifications, and in the adornment of rooms, corridors, and entrance halls there is no other class of plants to surpass them.

Although many of the species attain such large dimensions in their native habitats, quite a number possess a sufficiently dwarf habit to admit of their being grown for a number of years in comparatively small pots.

Palms may be divided into two groups: those possessing fan-shaped leaves, such as Chamaerops and Livistona, and those known as feather-leaved Palms, of which Kentia and Phœnix are good examples.

Culture. — The cultivation of Palms is by no means difficult, their chief requirements being good drainage and an abundant supply of water in summer, less, of course, being needed in winter, although their roots must never approach dryness.

The general method of raising Palms is from seeds, which are imported in large quantities from their native countries. The seeds

should be sown thickly in pans or boxes filled with a mixture of loam, leaf-soil, and sufficient sand to make it porous, covering them with about their own depth of soil. The pans should then be placed in a brisk temperature of 65–70° F., and kept moist. Germination will be hastened if the pans are plunged in a bed with bottom heat.

When two leaves have formed, the young plants should be placed singly into small pots, maintaining a high temperature and moist atmosphere. They require a fair amount of light to prevent them from becoming drawn, but should be shaded from bright sunshine. Liberal waterings both at the root and overhead will be required from now onwards, and as the pots become filled with roots the plants should be moved into a larger size, using a compost consisting of two parts fibrous loam to one of leaf-soil, with sufficient sand added to keep it open.

Palms succeed better when potted firmly and kept in small pots. Unless the roots are lifting the soil above the rim of the pot, it is better to apply a top-dressing in which a small proportion of some reliable concentrated manure, such as guano, is added, or water them with manure water made from cow manure and soot. By such treatment they can be kept in a healthy state for a considerable time.

Although tropical Palms delight in a warm, moist atmosphere, many of them will endure the cooler and somewhat dry conditions of a greenhouse, providing the temperature does not fall below 45° F. in winter. As, however, these last are rather troublesome to grow, they cannot be generally recommended.

Palms are liable to attacks of insect pests, such as mealy bug, red spider, scale, and thrips. When badly infested the leaves soon become disfigured, and the plants completely lose their value for decoration. The most effectual mode of destroying these pests is by carefully washing the leaves with a sponge and soapy water or some reliable insecticide.

SELECTION OF PALMS.

The following list contains those Palms which are most suitable for the decoration of the conservatory and the dwelling-house.

Archontophœnix Cunninghamiana.—This favourite ornamental Palm is frequently met with under the name of *Seaforthia elegans*. It is a native of Queensland, where it grows to a height of 60 ft. In a young state it is a most useful Palm for the conservatory.

Chamaedorea. — This comprises about sixty species, all natives of tropical America. *C. corallina* and *C. glaucifolia* are both elegant, slender-growing species with pinnate leaves.

Chamaerops humilis.—This is a low-growing Palm with fan-shaped leaves. It thrives in the open air in summer, and is frequently used in sub-tropical bedding. Propagation may be effected by means of suckers which are freely produced at the base. It is of interest as being the only Palm indigenous to Southern Europe. It grows about 10 ft. high.

Chrysalidocarpus lutescens (Syn. *Areca lutescens*). — This is one of the most popular and ornamental of Palms. It produces numerous stems, and the long, plume-like leaves are bright green, with yellow petioles. It is a native of Madagascar, growing about 20 ft. high.

Cocos.—This is a very beautiful genus of stove Palms. The most

popular for decorative purposes are *C. plumosa* and *C. Weddelliana*. The latter is a dwarf Palm from Brazil; it seldom exceeds 4 ft. in height. The graceful, pinnate leaves are rich green above and glaucous beneath. It is a Palm which delights in heat and moisture.

The former, also a native of Brazil, is a robust species with dark green, plume-like leaves. It is a useful Palm in the decoration of large halls.

Geonoma gracilis.—This is a very elegant plant, with dark green, arching leaves, closely resembling those of *Cocos Weddelliana*. It is a native of Brazil.

Howea Belmoreana and *H. Forsteriana* are undoubtedly the most popular of all Palms, and for elegance, combined with the rough treatment they will endure, there is no other Palm to surpass them for beautifying rooms and corridors. They are generally known under the name of *Kentia*. *H. Belmoreana* differs from *H. Forsteriana* in having the pinnate leaves beautifully arched, whereas in *H. Forsteriana* the leaves spread horizontally. They are both natives of Lord Howe's Island, and grow 10–30 ft. in height.

Livistona australis.—This is an ornamental, fan-leaved Palm, perhaps better known as *Corypha australis*. It forms a splendid specimen for the conservatory, and is also useful in the sub-tropical garden during summer. A native of Eastern Australia, it will grow up to 80 ft. high.

L. chinensis (Syn. *Latania borbonica*) is one of the commonest of Palms, bearing large, fan-shaped leaves. The hardy constitution of this plant renders it most useful for general decorative purposes. A native of China and Japan, it will grow 20–40 ft. in height.

Phœnix.—This is a very handsome genus of feather-leaved Palms. In a young state they are among the most useful for the decoration of rooms, while larger plants may be employed with advantage in the sub-tropical garden. A greenhouse temperature will suit them in winter. A few of the best are: *P. canariensis*, which produces a large and graceful head of leaves; *P. dactylifera*, the DATE PALM,[1] which much resembles the former, though the leaves grow erect; and *P. humilis Roebelini*,[2] which is undoubtedly the gem of the genus, and of late years it has become a favourite pot plant. This last is a dwarf Palm, having the leaves arranged in a very symmetrical manner. It is a native of Siam. The height of these PHŒNIX PALMS, as they are sometimes called, varies greatly; the dwarf form grows 2–10 ft., while others will be up to 50 ft. high.

Rhapis flabelliformis and *R. humilis* are two slender-growing Palms with fan-shaped leaves. In appearance they are much alike, but the leaves in *R. humilis* are larger. They are both ornamental plants, and will stand a considerable amount of rough treatment. They are natives of China and Japan, growing about 6 ft. high.

Rhopalostyle (Syn. *Areca*).—This is a genus of two species of greenhouse Palms, especially useful in a small state. *R. Baueri* comes from Norfolk Island, whilst *R. sapida* is the NICKAU PALM of New Zealand.

Trachycarpus excelsus is perhaps better known under the name of *Chamaerops Fortunei*. It is one of the commonest and most useful

[1] It does not fruit in this country.

[2] This variety will probably be recognised as a species in the near future.—EDITOR.

of Palms. In many parts of Great Britain it is quite hardy, and specimens planted on lawns are frequently met with. It is also one of the best greenhouse Palms, and being a slow grower, it is many years before the plant becomes too large for a small house. A native of China and Japan, it grows 20–30 ft. high.—T. W. T.

PAMPAS GRASS.—See *CORTADERIA*, *GYNERIUM*, and *ORNAMENTAL GRASSES*.

PAMPHILUS.—See SOCIAL PEAR SAWFLY IN *INSECT PESTS*.

PANCRATIUM (Nat. Ord. Amaryllidaceæ).—This is a genus of attractive bulbs, of which there are very many stove species. The hardy one which concerns us, *P. illyricum* (Syn. *P. stellare*), and its half-hardy brother, *P. maritimum*, both bear white flowers in May or June, and grow 1½–2 ft. in height. They are of easy culture, thriving in ordinary light, rich, loamy soil, to which some peat has been added, and can be planted in the autumn or early spring. They can be propagated either by seeds or by offsets in the usual way. *P. maritimum* requires protection in the winter.

PANIC GRASS.—See *PANICUM*.

PANICUM (PANIC GRASS. Nat. Ord. Gramineæ).—This is a genus of hardy and half-hardy annual and perennial grasses, mostly of easy culture, though they are interesting botanically rather than good garden plants in this country. *M. colonum* is the MILLET RICE; *P. Crus-galli* is the BARNYARD GRASS; and *P. miliaceum* is the MILLET used for the feeding of fowls. *P. plicatum*, a half-hardy perennial, is sometimes grown in pots. It is elegant in habit, and grows about 2½ ft. high. *P. virgatum* is a good wild-garden plant about 4 ft. high. To give cultural details of these and other species is at present beyond our scope.

PANSY (Nat. Ord. Violaceæ).

Culture of.—The culture of the pansy is quite a simple matter, and although this old favourite has been somewhat eclipsed by the newer Tufted Pansies or Violas (see article on *VIOLA*), there are many gardeners who still grow it, and many more who wish to grow it well, hence this article.

Our first consideration in the matter of pansy cultivation is the purpose for which the plant is to be applied. It can, as is well known, be best used as an edging to herbaceous and other borders, or it may be used for carpeting, and again as a mixed plant among herbaceous subjects. Personally we prefer the neater violas as edging plants, since they are perpetual flowering, if attended to in the matter of clipping off the dead flower stems, but this cannot be said of the pansy. About the middle of July this plant invariably gets untidy. Long, leggy stems which have borne numerous flowers lie on the ground, and the plant presents a deserted appearance. Thus it is best used as an addition to the herbaceous border, from which it can be lifted and attended to when it gets untidy or past its best.

As to soil and site, the pansy is not at all fastidious. A light, well-drained loam, nicely enriched with rotten manure is quite suitable, and the position may be either in full sun or in semi-shade. Pansy culture on peat loams is not so successful as on those of a more alkaline nature, a fact which should be borne in mind by gardeners having soils inclined to acidity, in which case mortar rubble or any

other form of lime should be freely dug in, prior to planting.

The planting of pansies can be done either in the spring or in the autumn; as they are perfectly hardy there need be no fear of losing any by the frost, but there is great fear of fatalities owing to pests, such as slugs and snails. Suffice it must to say here, that where the soil is full of pests, new stock should be wintered in a frame, and planted out permanently somewhere about the middle of March. As with all other subjects, firm planting is essential for pansies. The distance from plant to plant may vary, according to size, from 6 ins. to 12 ins.: planting at a distance of 3 ins. apart to make a display is not recommended, as it means that the subjects will be somewhat starved by being so close together.

Propagation.—Pansies are very easy to propagate, either by seed, division of the rootstock, or by cuttings. Seed can be sown in the open ground in a slightly shaded position from June onwards, the plants pricked out in a cold frame, wintered there, and planted permanently the following spring; or seed may be sown in heat in February, the plants being pricked out and hardened off as soon as large enough, and finally set in their permanent positions early in April. These will flower the same year. Seed is easy to save, and it can be sown as soon as ripe, but, needless to say, after seed is saved the length of the blooming period of the plants is very much curtailed.

Propagation by division is also fairly simple. The old plants, aged two years or more, are lifted and cut into three or four pieces with a sharp knife. The strongest sections are then replanted in rows in the reserve garden, 9 ins. apart each way, watered, and kept well hoed all the rest of the season. This may be done in July.

Cuttings also are easy to strike. The old plants are lifted after finishing flowering in July, and cut down to within a few inches of the ground; thus all the leggy growth is disposed of. They are then planted close together in the reserve garden or in a frame, in light soil, well soaked with water containing a little nitrogenous fertiliser, and in a very short time numerous young shoots will appear. These are cut off when about 2 ins. long, in the usual way, just below the joint, and pegged into sandy soil 3 ins. apart each way, in a lightly shaded frame. A thorough watering is given, after which the lights are closed until rooting takes place, which will be in three weeks or so. Some people plant the pansies out the same autumn, but we prefer to keep them in a frame, giving air on all suitable occasions until March, after which they are hardened off and planted out permanently.

Varieties.—The Pansies grown today are all Fancy or Belgian Pansies. They produce much larger flowers than the old Show Pansies did, and the range of colour is vastly more varied. Most of the leading seed firms make a speciality of Fancy Pansies, and have fine strains of their own of which they supply seed. Several nursery firms make a speciality of growing named varieties, and propagate them annually by cuttings. Such firms advertise from time to time, and readers should send for their lists or consult the National Pansy and Viola Society, since any selections given here would be very quickly out of date.

Bedding Pansies.—These may be called the remnants of the old Show Pansies, as they are mostly blue, white, and yellow selfs, with

small blotches of a different colour on the lower outside petals. They are offered in seed, and are treated as seedlings for bedding, being very effective if grouped in large masses, though Violas (see article on *Viola*) are more popular still for this purpose.—E.

PANSY : Historical Notes.

The Pansy has long been a favourite in the flower garden. Poets have sung its praises since the days of Spenser, Shakespeare, Herrick, and Milton; while its popularity among the humble cultivators of the flower in our country homes and cottage gardens has earned for it all sorts of queer appellations, such as Three Faces under a Hood, Herb Trinity, Flame Flower, Pink of my John, Flower of Jove, Love in Idleness, Cuddle-me-to-you, etc. Heartsease, perhaps, is the most common of all, and the most general in use.

Certain modern writers would have us believe that the garden Pansy is a recent product, the result of about a century's work in seeding and improving the wild *Viola tricolor*. But this theory cannot hold water when we dip into the records of the past. Thompson, or Thomson, of Iver, Bucks, and Richardson, gardener to the Earl of Tankerville, both appear to have started improving the Pansy about the years 1810–13. There is every reason to suppose that then and for some years afterwards seedling raisers, by dint of hybridisation, selection, and careful cultivation, did much to improve the flower and raise it to the standard of a florists' flower.

But it is equally certain that centuries before either of these gardeners began to work on the improvement of the Pansy, the flower was known and grown as a garden flower. Up to a point it is more than probable that by cross fertilisation the Pansy had passed from its primitive form and had already become a popular favourite, for in all the old Herbals and florists' books at home and abroad the Heartsease or Pansy almost invariably finds a place.

From a summary of a paper in Swedish by Professor Wittrock of Stockholm, we learn that the name Pansy was used for the first time in 1537 by Ruellius under the Latin form Pensea. The earliest mention of *Viola tricolor* is by Brunfels (1536) and Fuchs (1542), both German writers, in whose country the Pansy has long been grown. Its popular name there is Stiefmütterchen. From the point of view of size, *Viola lutea* and *Viola grandiflora* were far superior to *Viola tricolor*, and by crossing these with others, such as *Viola Altaica*, *V. rothomogensis*, etc., there is good reason to suppose that a race of attractive garden Pansies or Heartsease was obtained and regularly grown by flower lovers long before the beginning of the nineteenth century.

The flower can be traced back beyond the days of Gerarde and Parkinson, as already indicated. Other references and figures of it under different names can be found in the *Hortus Eystettensis*, in Weinmann, in Clusius, in Matthiolus, and many more of the old botanical writers and compilers of Herbals. Sometimes we meet with it as *Viola flammea*, at others as *Flos Trinitatis*, *Jacea Trinitatis*, Pensée, or the like.

We cannot in the limited space at our command deal fully with the many references to the Pansy by the poets, botanists, and floriculturists of the olden times. A few brief references must suffice to show that it had a considerable hold on the minds of our forefathers who took an interest in the flower

garden. Thus John Evelyn in his *Kalendarium Hortense* (3rd ed. 1669) refers to "Pansys" and "The Yellow Mountain Heartsease." Pierre Morin, an eminent Parisian florist, whom Evelyn visited on one of his journeys abroad, in a little handbook on the culture of flowers published in 1670, refers to "Pensées" in his list of fibrous-rooted plants generally to be found in the pleasure garden.

Joseph Carpenter in 1717, in his edition of *The Retir'd Gardener*, heads a chapter "Of Pansies," in which the culture and description are given.

Leonard Meager's *New Art of Gardening*, dated 1718, includes Heartsease under the heading of "Flowers blooming this Month" (August); and to carry our dates on still further we find that Stevenson in *The Gentleman Gardener*, published in 1766, says "Pansy or Heartsease is also by some called *Viola tricolor*, on account of the three colours that are in this flower."

Many more might be quoted more or less fully had we the space at our disposal. We will conclude with one as late as 1800, when Charles Marshall in his *Plain and Easy Introduction to . . . Gardening* mentions the "Hearts Ease or Pansey, large Dutch, &c., a variety."

From this date, or shortly afterwards, the Pansy was seriously taken in hand by English florists, of whom Thompson, or Thomson (the spelling of the name is uncertain), was one of the leading pioneers, and it is beyond question that a great impulse was given to its cultivation in this country by him and other raisers during the early part of the nineteenth century.

Exhibitions of Pansies were instituted throughout the United Kingdom, and by dint of skilful culture that peculiar form at one time so much appreciated and known as the Show Pansy was finally evolved. The principal sections in the old days were the Show Pansies, comprising four types: the dark selfs, the white or yellow selfs, the yellow grounds, and the white grounds. These latter, with their blotch and belting, were subject to very severe rules. The Fancies were a section distinguished by a different marking; but there are to-day but few growers who are interested in these peculiarities and rigid distinctions of the old school of florists.

The Viola or Tufted Pansy, now so generally appreciated for bedding purposes, is a race apart and of more modern production. Cross fertilisation and hybridisation by such famous growers as Dr. Stuart, James Grieve, John Baxter, and others has resulted in a type of far greater utility for garden decoration than its precursors. It may be observed that in the production of the bedding Viola or Tufted Pansy the species known as *Viola cornuta* played a considerable part.

Later still than the Viola, commonly so called, is the *Violetta*, a section of miniature pansy-like flowers, very dwarf, and also the progeny of a cross by Dr. Stuart in which *Viola cornuta* was used. For rockwork this section has much to recommend it.—C. H. P.

PANTHER CAP. — See HARMFUL FUNGI in *FUNGI: EDIBLE AND HARMFUL.*

PANTHER LILY (*Lilium pardalinum*). See *LILIES* and *WATER GARDEN: PLANTS FOR THE.*

PAPAVER.—See *POPPIES*, and under OPIUM POPPY in *MEDICINAL HERBS.*

PAPER AS GLASS.—See *GLASS SUBSTITUTES.*

PAPER BIRCH (*Betula papyrifera*).—See *TREES.*

PAPER MULBERRY (*Brousonetia papyrifera*).—See *TREES.*

PAPER WHITE NARCISSUS (*Narcissus Tazetta papyraceus*). — See *NARCISSUS SPECIES*.

PARADISE STOCK. — See under STOCKS USED in *FRUIT CULTURE, HARDY: GENERAL CONSIDERATIONS*.

PARADISEA LILIASTRUM.—See *ST. BRUNO'S LILY*.

PARAFFIN EMULSION.—This is not used now to any large extent by the best gardeners.

PARAFFIN JELLY. — See *INSECT PESTS: GENERAL METHODS OF DESTRUCTION*.

PARAGRAMMA.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING*.

PARASITES. — See *FUNGOUS DISEASES*.

PARASOL DE ST. JULIEN (*Populus tremuloides pendula*).—See *TREES*.

PARDIA.—See under ROSE GRUBS in *INSECT PESTS*.

PARIETARIA (PELLITORY. Nat. Ord. Urticaceæ).—This is a genus of perennial weeds bearing pale purple flowers in June, which is to be avoided rather than cultivated. *P. officinalis* (Syn. *P. diffusa*) was once much used in herbal medicines for cases of stone, but PARSLEY PIERT (see article on *MEDICINAL HERBS*) now seems to have taken its place.

PARIS (HERB PARIS. Nat. Ord. Liliaceæ).—Two species of this figure in the *Kew Hand-list of Herbaceous Plants*. These, *P. polyphylla* and *P. quadrifolia*, are hardy herbaceous perennials of the simplest culture, with greenish flowers in May, on plants 6 ins. high. They are only worth growing in very large collections, and it is well to note that they are no longer of much importance as medicinal plants.

PARIS GREEN.—See under COPPER ACETO-ARSENITE in *COPPER AND CUPRUM COMPOUNDS*; and also *INSECT PESTS: GENERAL METHODS OF DESTRUCTION*.

PARLOUR PALM.—See *ASPIDISTRA*.

PARNASSIA (GRASS OF PARNASSUS. Nat. Ord. Saxifragaceæ).—All the species of this genus are usually regarded as water or bog plants, but that is not the case. *P. asarifolia* (Syn. *P. nudata*) and *P. caroliniana* (Syn. *P. americana*) will succeed in ordinary or rock borders which are kept very moist, and which are shaded from strong sunshine. They both bear white flowers in May, are hardy herbaceous perennials, and average about 6 ins. in height. The two best sorts for the water garden are described under GRASS OF PARNASSUS in our article on *WATER GARDEN: PLANTS FOR THE*.

Rock Garden Species. — These include some perennial bog plants of tufted habit suitable for the moister parts of the rock garden. They may be propagated by division of the roots in the spring, or by seeds sown in March in a little heat. *Parnassia palustris*, referred to in the above named article, is the best. It bears leaves in tufts, and white flowers on erect stems. It succeeds in an open site in boggy or peaty soil, flowers from June to August, and averages 6–9 ins. high.

PARROT TULIPS.—See *TULIPS*.

PARROTIA.—For the best species see *SHRUBS*.

PARSLEY (*Carum Petroselinum*. Nat. Ord. Umbelliferæ). — No vegetable garden is complete without its rows or beds of Parsley, as the plant is a universal favourite for garnishing and for the making of Parsley sauce. The idea that it is difficult to grow has little foundation in fact.

Culture.—If an abundant supply of large, well-curled leaves is wanted, this need not be expected if the plant is relegated to any old corner or set in soil of indifferent quality. A rich, well-worked soil, free from

lumps of recently applied manure, is the best, and the site, while fairly open, should not be fully exposed to the glare of midday sun.

Sow the seed either broadcast or in drills—the latter for preference—and cover lightly with soil. Pay a good price for the seed to be sure of getting new stock, as old seed germinates very badly. Sowings may be made outside from March to May, and indoors or in frames during February and September. In any case, the seedlings should be thinned out so that they stand 9 ins. apart each way, and the hoe should be kept going throughout the season for the dual purpose of killing weeds and stimulating growth.

Parsley transplants fairly well, provided water be copiously supplied after this has been done. Plants should be put 9–12 ins. apart, and form suitable subjects for edgings to vegetable borders. Weak liquid manure will be necessary if plants of very high quality are required.

If a supply is wanted in the winter, a cold frame should be put up in a sheltered position in the garden, and this filled with September-sown plants from another frame, putting them 3–6 ins. apart each way. Care should be taken to keep the frame well covered in during frosty weather.

Varieties.—Numerous strains are offered in seedsmen's lists, but none are better than the following: Champion Moss Curled, Clibran's Exhibition, Double Curled, Dwarf Fern-leaved, Hardy Winter, Myatt's Garnishing, and Triple Curled.—E.

See also *CARUM* and *ORNAMENTAL VEGETABLES*.

PARSLEY BREAKSTONE.—See under PARSLEY PIERT in *MEDICINAL HERBS*.

PARSLEY, FOOL'S. — See FOOL'S PARSLEY in *WEEDS*.

PARSLEY-LEAVED BLACKBERRY. See *BRAMBLES AND BERRIES*.

PARSLEY-LEAVED THORN (*Crataegus apiifolia*).—See *TREES*.

PARSLEY PIERT.—See *MEDICINAL HERBS*.

PARSNIP (*Peucedanum sativum*. Nat. Ord. Umbelliferæ).—This is one of the most accommodating of all crops we grow in this country, and, on account of its great food value, deserves to be even more largely grown. Fortunately for the town gardener, the plant is not at all fastidious in its requirements; land on which other crops fail invariably proves profitable sown with parsnips.

Culture.—Extra heavy or clayey soils will be improved by the addition of a fair quantity of finely sifted ashes or road scrapings. Where the soil is light and a proper system of cropping has been observed, seeds of any variety mentioned below will give roots of excellent quality, perfect in size and appearance, on land well manured twelve months before.

Seed must be sown as early in the year as the state of the soil admits; therefore prepare the bed in good time,—the sooner the better,—double digging or double trenching it if possible.

In sowing the seed, instead of filling the row, seed will be economised and labour saved if it is dropped not more than three in a place at intervals of 9 ins. Should more than one of these germinate, remove the surplus as soon as the strongest can be selected; these, if carefully lifted, will bear transplanting elsewhere. Cover seeds with an inch of soil, leaving the rows 1 ft. asunder. The occasional use of the hoe between the rows of plants is advisable for the dual purpose of stimulating growth and keeping weeds under for the season.

Beyond this no further attention

need be given until the early days of November, when two courses are open to the grower. He may lift the whole crop and store as advised in article on *Carrot*, or allow it to occupy the ground until required for use. This latter method, although assuring the best table quality, has the disadvantage of being likely to cause considerable inconvenience should the winter be exceptionally severe, or snow render the location of the roots difficult.

Varieties include Hollow Crown, Large Guernsey, Marrowfat, New Century, New Maltese, Student, Tender and True.—F. R. C.

PARSNIP CANKER.—See *Diseases of Plants*.

PARSNIP FLY.—See under Celery Fly in *Insect Pests*.

PARSNIP-ROOTED CHERVIL.

This, sometimes known as Turnip-rooted Chervil, can be boiled and used similarly to Parsnips. The crop is but little grown on account of the fact that the best results can only be obtained by sowing early in heat. Really the crop has but little to commend it, as it is not nearly so good as a well-grown Parsnip.

PARSNIP-ROOTED PARSLEY.

This, also known as Hamburgh Parsley, is a comparatively little known vegetable in this country. It may be grown in much the same way as other long-rooted crops in deep, well-worked soil, though it cannot be said to be as good a vegetable as the true Parsnip.

PARSNIP WINE.

Although most people who grow parsnips do so in order to be assured of a good wholesome vegetable for winter use, there are others, notably in many country districts, who, being aware of the health-giving value of the Parsnip, sow an abundance of the crop for making Parsnip Wine. The writer of this note had the pleasure of working daily in the garden for a period of fourteen years with an old villager to whom wine, made according to the recipe below, had been his chief drink (save, of course, the usual daily non-intoxicating beverages) for nearly seventy years. No matter from what ailment his wife, self, or neighbours may be suffering, a good glass of Parsnip Wine is the remedy, and if my information was correct, and I have no reason to doubt it, the prescribed drink invariably had the desired effect; and although not exactly non-intoxicating, I have his word for it that it would take a great deal to make a man lose his head.

How to Make it.—To every pound of well-washed parsnips add a quart of water, preferably that which has been boiled. Cut the roots up into quarters, place them in a large boiler, and boil slowly until really soft. Strain the liquor through a fine sieve or piece of muslin, adding sugar (Cane or Demerara sugar is the best), at the rate of three pounds to each gallon of water. Let this stand overnight in a large earthenware pan or clean wooden tub covered with a clean cloth.

The day following, add a quarter of a pound of brown ginger to each four gallons of liquid, also a good-sized handful of hops (either fresh from the hedge where they grow wild, or dried as obtained from the chemist or grocer), placing these in a loose muslin bag.

Next get a slice of bread nicely toasted; upon this put a heaped tablespoonful of fresh yeast, or its equivalent of the prepared article usually obtainable from the baker, and add this to the "wine."

When the liquid is seen to be working freely, place in a wooden keg, or in very strong stone jars,

corking these securely, afterwards standing in a cool place.

Glass bottles should not be used, for if very warm weather follows and the storage is not cool the wine will "work" so freely that either the corks blow out or the bottles burst.

Whenever possible, keep the liquid at least six months before use, for the older it is the clearer and stronger it becomes.—F. R. C.

PARTRIDGE BERRY (*Gaultheria procumbens*).—See *SHRUBS*.

PARTRIDGE MANURE.—See *POULTRY MANURE*.

PASPALUM (Nat. Ord. Gramineæ). This is a genus of hardy and tender grasses of small value and easy culture. The two most important species are *P. pubiflorum* and *P. virgatum*, both known as BASTARD MILLET, averaging 1½ ft. in height. MILLET (True) is referred to in our article on *PANICUM*, to which genus it belongs. The plant under notice must not be confused with it.

PASQUE FLOWER (*Anemone Pulsatilla*). — See *ANEMONE: ROCK GARDEN SPECIES*, and *MEDICINAL HERBS*.

PEA TREE.—A name applied to the genus CARAGANA. See *SHRUBS*.

PEA TRIBE.—See *KINDS OF CROPS*.

PEACH DISEASES.

The following three Peach diseases are of interest and importance to growers of this fruit.—EDITOR.

Peach Leaf-curl (*Exoascus deformans*). — This disease is very common on outdoor peaches. It affects the young leaves and shoots, which become puckered, twisted and thickened, and blotched with pink. Severe cases cause defoliation, loss of crop, and injury to the tree. Cool, damp weather favours the disease.

REMEDIES.—Spraying with 2 per cent. Burgundy Mixture (see article on *SPRAYING MIXTURES*), with the addition of a little milk to make the spray adhere to the leaves, has been found very efficacious. It is essential that the spray should be applied *before* the leaf buds open, *i.e.* usually about the middle or end of February, and as a rule one spraying is sufficient. All dead twigs should be removed, and diseased parts cut out and burned.

Peach Mildew (*Sphaerotheca pannosa*).—This forms a white, mealy coating on the young leaves and shoots of the peach, often checking their growth and causing defoliation. It also attacks the fruit.

REMEDIES.—Dusting with sulphur is the best treatment in this country. The powder should be applied early before the disease becomes serious, and repeated till it is thoroughly under control.

Peach Shot-hole.—The leaves of various fruit trees, especially peach, are often found to possess small, circular holes. These were formerly thought to be due to the fungus *Cercosposa circumscissa*, but recent observations show that this is seldom the case, and indicate that they may be due to the action of the tree itself excising portions of tissue which have been injured by insect bites, scorch, or other agency. No remedy is known.—A. D. C.

PEACH LEAF-CURL.—See *PEACH DISEASES.*

PEACH MILDEW. — See *PEACH DISEASES.*

PEACH NETTING. — See *GARDEN NETTING.*

PEACH SCALE.—See under BROWN SCALES in *INSECT PESTS.*

PEACH SHOT-HOLE.—See *PEACH DISEASES.*

PEACHES (*Prunus Persica.* Nat. Ord. Rosaceæ).—These delicious fruits are extensively grown under glass, the success or failure of which depends upon the different details of management being carried out at the proper time, and no dessert from May to October is considered complete without them. Nothing could give more pleasure than a house full of ripe fruits, and no country can equal the delicious fruits grown in England. Span-roofed and lean-to houses, the former running north to south, the latter facing south or south-west, are the most suitable, and a nice light lean-to is the best for early forcing. Another advantage now in early forcing is the command of the new varieties of recent introduction, which ripen the fruit much in advance of the older varieties. Size of houses must be regulated according to demand; 18–20 ft. in length, and not less than 15 ft. in width, should be allowed for each trained tree, with sufficient hot-water pipes to keep up the requisite temperature without getting the pipes too hot. Pot-peaches are the best for early forcing; a span-roof house will hold the most trees; space allowed will be according to the size of the tree, selecting varieties according to requirements. Success depends a good deal upon the way the trees are potted and the compost used. A fairly heavy loam should be selected; generally speaking, two-thirds should be loam. Lime must be supplied in some form, by lime-rubble, old plaster, or broken chalk; also add some charcoal and burnt ashes, with 10–15 per cent. of bonemeal. Although annual pottings are not often recommended, and the trees fruit well for two seasons, our experience is they fail the third, and for all practical purposes the soil is exhausted after one season's growth owing to the small size of the pot. Use clean pots carefully crocked; and with the soil in a medium state of moisture, it is almost impossible to pot too firm.

Disbudding.—Pruning and pinching can only be successfully carried out by experience, as peaches and nectarines, like other trees, vary considerably both in habit and growth. If ripe fruits are required in May with such varieties as *Cardinal, Duke of York, Early Rivers,* and *Peregrine,* the house need not be closed till January. Allow the house to start gradually, 40° F. at night as the minimum and 48° F. as the maximum, with free ventilation till they reach the flowering stage on all favourable occasions. Do not exceed 50° F. at night until after the stoning period. A circulation of warm sweet air must be procured in damp weather by artificial means and careful ventilation.

Permanent Trees.—Unless natural draining is satisfactory, artificial

drainage must be provided, as the peach requires abundance of water throughout the growing season. After deciding on the level, excavate about 3 ft. below the surface; prepare drains and drainage in a similar manner to that recommended for vines, allowing for 2 ft. of compost. The piecemeal system of making the border is the best, and 6 ft. by 4 ft. for two- or three-year-old trees will be wide enough. Loam of a rather strong calcareous nature should form the main staple; chop up roughly, add lime and brick rubble, burnt earth, and road scrapings—one or all may be used, or the most convenient. No fresh manure is needed, but half a bushel of bone-meal and half a bushel of ½-inch bones with a peck of soot may be added to each cartload. In a wet subsoil the border should be raised above the ground level. Make it firm and allow it to settle down, after which planting is a simple operation. Spread out the roots in every direction, cut off damaged points, and work the soil well in amongst the roots, 4 ins. above the roots being ample. Give the tree a good watering with a rosed-can to settle the soil amongst the roots. Large trees if prepared may be planted at almost any season, but when prepared and planted early in the year will carry a fair crop of fruit the first season. Water well, and mulch with short manure; keep the house cool, tying the tree rather loosely for settling down. Moisture becomes necessary when closed, and must be supplied by syringing and damping of the paths, etc., until the trees are in flower, when a drier and warmer air is recommended, although through this stage moderate moisture should be supplied by damping the floors on fine days. After the fruits are set, regular syringing twice a day on fine days should be given, but always in time for the foliage to become dry before nightfall.

Training.—The fan system of training is the best, although Peaches answer to the cordon system equally well. A healthy tree produces a great number of superfluous buds, which have to be removed to prevent a tangle of shoots. It is necessary, after the tree is formed, to keep it evenly furnished with annual shoots for succession. Vigorous trees are always ready for disbudding first, and should have a few foresight shoots removed as soon as the fruits are set. Continue to remove other shoots at short intervals, selecting a well-placed shoot near the base, others 15–18 ins. apart, and the terminal bud for future extension. After the trees are making free growth, tie in the shoots neatly with soft matting to secure a straight branch after the bearing shoot is cut away. Avoid retaining more shoots than are required to furnish the tree. Gradually thin the fruits, commencing when they are the size of peas, again when they attain the size of nuts, leaving a small surplus to allow for any loss during stoning. After stoning is completed the final thinning should take place, leaving all the best-placed fruits on the upper side of the shoots, removing all as far as possible underneath. A great difference of opinion exists as to the number a tree may carry. One to every square foot is near enough for large peaches, and one to every hundred square inches for nectarines.

Fertilisation.—As a rule, when other conditions are right, plenty of fruit sets without artificial aid; still, all early houses should be gone over with a brush from one tree to the other, and repeated from day to day until the latest begin to drop their petals.

Watering.—Trees when inside

require continuous supplies of water, but no rule can be laid down, as so much depends upon the elevation, formation, and depth of the borders. The roots should never be allowed to become dry, otherwise failure is sure to follow, and the quantity of water must be regulated by the age and condition of the trees, as also must the use of stimulants. Use soft water in supplying moisture by syringing and damping. Fumigate the house just before the flowers open, and again after the fruits are set, or at any later date if fly is troublesome, and discontinue syringing when the fruits are ripening.

Ventilation and Temperatures.—All stone fruits require plenty of ventilation, especially through the early stages, and including the setting, stoning, and colouring of the fruits. Time must be given by starting them at a low temperature; 45° F. is high enough with artificial heat to start with; in mild weather it will be higher with ventilation. Commence with 45° F. to 50° F., increasing to 50° F. at night when the blossoms open, and 60° F. by day; after the fruits are set, 56° F. to 60° F. at night, with 10° higher on fine days. Later houses must be regulated by external conditions, always with a chink of air on top and front ventilation.

VARIETIES TO GROW.

Bellegarde.—A fine large peach of excellent quality.

Duke of York.—The finest early peach for forcing.

Dymond.—A highly coloured hardy and prolific peach.

Goshawk.—A large pale-coloured peach of fine flavour.

Peregrine.—A handsome fruit, excellent for all purposes.

Princess of Wales.—A rich and beautiful late peach.

There are many other good varieties which may be included in large establishments, such as Alexandra Noblesse, Grosse Mignonne, Royal George, Stirling Castle, and Thomas Rivers.

Nectarines.—The same cultural remarks as recommended with regard to peaches apply to these fruits. Nectarines have a smooth skin and peaches a rough one.

VARIETIES TO GROW.

Dryden.—A large high-coloured and fine-flavoured nectarine.

Early Rivers.—The best early forcing, excellent for all uses.

Humboldt.—A large handsome fruit of fine quality.

Lord Napier.—A large, reliable, and excellent variety.

Pineapple.— A large, high-coloured, very rich, deep orange fruit.

Victoria.—A late greenish-yellow fruit of fine flavour.

Other good varieties are:—Darwin, Improved Downton, Newton, Rivers' Orange, Spencer, Stanwick, and Violette Hâtine. F. J.

PEACHES: Outdoor Culture. — See *NECTARINES AND PEACHES: OUTDOOR CULTURE.*

PEACOCK DUNG. — See *POULTRY MANURE.*

PEACOCK POPPY (*Papaver pavoninum*).—See *POPPIES.*

PEACOCK TIGER IRIS (*Tigridia Pavonia*).—See *TIGER IRIS.*

PEAR (*Pyrus.* Nat. Ord. Rosaceæ). — **Culture of.** — If the reader will study the general considerations on Hardy Fruits included in this work, he will agree with us that no lengthy detailed article on the Pear is necessary here. The culture of the pear and the apple are very similar, and can be carried out without difficulty by any gardener who has digested our general considerations.

Therefore, it will suffice to say

here that of the two stocks on which pears are grafted, the free or seedling Pear stock is in most demand for espaliers, pyramid trees, and standards, while the Quince is the stock used for grafting when smaller trees are required, *i.e.* when the gardener wishes to grow bush pears, cordon trees, and smaller pyramid specimens. It is well to remember that it is not every variety of pear that will thrive when grafted on the Quince stock; the most notable failures being found in *Beurré Bosc, Blickling, Passe Crasanne,* and *Souvenir de Congrès,* our hardy fruit contributor informs us. The following selection contains the cream of the varieties, arranged in the months during which they ripen.—EDITOR.

DESSERT PEARS.

September :—*Jargonelle.*—Medium size. Growth free and weeping. Best as a standard or wall. Gather before quite ripe or the fruits become mealy. A juicy and refreshing sort.

William's Bonchretien.—Large, too well known to need description. Succeeds in any form. Gather as for *Jargonelle.*

October:—*Conference.*—Large, russety; a handsome long fruit. Compact growth, very free and constant bearer. Rich, spicy flavour. Splendid.

Louise Bonne (of Jersey).—Medium size. Deep crimson cheek. Compact growth; free bearer. Very juicy and sweet.

Marguerite Marillat.—Very large, yellow. Compact erect growth, and good as a cordon. Unsuitable for espalier culture, but makes a close bush. Of the richest perfumed flavour.

November :—*Doyenné du Comice.*—Large, rich golden with russet. Good in all forms—quite the finest of all pears. Juicy, very sweet, rich, and melting, with no grit. Moderate bearer.

Durondeau.—Very large and long. Russety, dark brown. Flavour very rich. Growth compact but free. Good in any form. Constant, reliable bearer.

Emile d'Heyst.—Large, yellow, spotted. Compact growth, good in any form. Flavour rich; juicy, melting flesh. Beats *Marie Louise.* Very free bearer.

Fondante de Thirriot.—Large, globe-shaped. Great bearer in any form. Very rich flavour, juicy, and refreshing. First rate.

Marie Louise.—This old favourite is included, but should only be placed on wall or fence.

Pitmaston Duchess.—Very large, deep yellow. Good in any form, bearing freely. A rich, juicy dessert fruit in warm seasons; but otherwise it is second rate; though then is grand for bottling or stewing. Flavour sweet, with acid tannin taste. Keeps fit for use into November. Good on wall.

December to April :—*Bergampt d'Esperen.*—Medium size, green, round, with long stalk. Bears so freely as to require severe thinning. Flavour rich, juicy.

Glou Morceau.—Large green, compact grower. Good bearer. A rich, juicy variety for warm soils or wall only.

Josephine de Malines.—Small, compact grower. Succeeds in any form, and lasts a long time in use. Very rich, aromatic flavour. Free bearer.

Nouvelle Fulvie.—Large, but awkwardly shaped. Rich brown, russety colour. Fair bearer, and one of the most reliable pears.

Further Kinds.—The following sorts may also be strongly recommended to growers who desire further variety :—

For September.—Aspasie Aucourt, Colmar d'Eté, and Souvenir de Congrès. This last is a failure on the Quince stock.

For October. — Beurré Hardy, Beurré Superfin, and Fondante d'Autômne.

From December to April.—Beurré de Naghin, Doyenné d'Alençon, Duchesse de Bordeaux, Easter Beurré, Knight's Monarch, and Winter Nelis.

PEARS FOR BAKING AND STEWING.

Bellissime d'Hiver. — Large; growth very sturdy and upright. Makes a good cordon or bush. Bears freely, and cooks to a sweetmeat.

Catillac.—Large, round, succeeds as a standard or on east or north wall; the growth is too awkward for bush culture. Good bearer, keeping till June.

Uvedale's St. Germain. — Often grows to 2 lb. in weight, and although large, it cooks well. Best on a wall. Moderate bearer, keeping till June.

Late Dessert Pears. — The late Dessert pears mentioned in this article need special care. The trees should be well mulched and fed while growing, and the fruit should be left on the trees well into November to perfect growth. They should be stored in a cool place, and as they commence to ripen, a few at a time should be brought into a warm place — this brings out their flavour. As mentioned in another article, they are of no use unless the garden has a proper Fruit House.—G. B.

PEAR AND CHERRY SAWFLY.—See under SLUGWORM in *INSECT PESTS.*

PEAR LEAF BLISTER MITE and PEAR LEAF BLISTER MOTH.—See *INSECT PESTS.*

PEAR LEAF CLUSTER CUP.—See *DISEASES OF PLANTS.*

PEAR MIDGE.—See *INSECT PESTS.*

PEARL-ASH.—See under POTASSIUM CARBONATE in *POTASH AND POTASSIUM COMPOUNDS.*

PEARL-WORT.—See *SAGINA.*

PEAS (*Pisum sativum.* Nat. Ord. Leguminosæ).—A kitchen garden without its rows of peas is unthinkable, and thanks to the efforts of modern raisers the cultivation of really profitable varieties is no longer restricted to those having large breadths of good, deep soil, upon which it is usual to grow numerous rows, the haulm of which approaches 6 ft. or more in height. Many of the most prolific varieties, possessing exceptional good table quality, are found among those which rarely exceed half the height just mentioned. The tall sorts, though much heavier croppers, and greatly in favour with professionals, are unsuitable for small gardens: first, on account of the difficulty in obtaining suitable sticks for the support of the haulm; and secondly, since they grow so high that they shade the land very much and make it quite unsuitable for other crops. Readers who can get good sticks should certainly try one or more of the newer tall-growing varieties; for even without adopting what is termed Exhibition culture the length of the individual pods, size of pea, and enormous crop will be a revelation to those who know only varieties introduced even twenty years ago.

Preparation of Land.—Almost any soil may be brought into a condition suitable for sowing either early, maincrop, or late peas. Heavy soils need deeply trenching, plenty of long, strawy manure being added late in winter; others of a light nature needing a liberal supply of well-decayed cow manure to be dug in early in the year.

Whenever possible, prepare a

portion of the garden especially for this crop, letting it be of sufficient width to accommodate every row sown from early spring until mid-summer.

By thoroughly trenching the whole plot in the winter, much labour will be saved at a period when it can least be spared. The results obtained will be far better than when the time-honoured plan of getting out the drills for these a few days before it is intended to sow the seed is adopted. If trenching is decided upon, very little more manure will be needed, yet the crop taken from each row sown will be twice as heavy as that which follows sowing in a hastily prepared trench.

Sowing.—In former days the chief reason why many failed to get the best results from peas was the common failing of sowing a quart of seed where less than half the quantity would suffice. Thin sowing may be said to be one of the secrets of success.

Owing to the superior flavour of the wrinkled, or marrowfat varieties, it is no longer advisable to sow seed of a round-seeded variety in the autumn in order to get an extra early dish; far better defer such sowings until the following year, and select good, early marrowfats which are not only of superior table quality and far heavier croppers, but if all goes well, produce may usually be had from these rows as early, or even earlier, than from autumn-sown rows. The time of sowing largely depends on local conditions, it being unwise to risk the loss of valuable seed too early, or while the soil is in a pasty condition. Generally speaking, on light soils the first sowing may be made about the middle of February, three weeks later being soon enough for soils of a retentive nature.

To succeed the early sown, more seed should be got in every fortnight until the end of May. For these sowings any of the later varieties recommended at the end of this article will give good returns. Sowings made in June should be limited to those varieties mentioned for earliest sowing. A pint of good seed will be ample for a row of 60 ft. long; in fact, sowings made during the month of May should be even thinner than this.

A great point to observe is, to give the haulm proper support early in growth. This may be done by placing twiggy sticks to the rows as soon as the plants appear above the soil, and others about a foot above the average height of the variety, before the tops fall over.

Watering and Mulching.—Plenty of moisture must be given during dry weather, but avoid the use of liquid manure until the first pods are swelling freely. Syringe overhead after a hot day, and if the peas promise to be backward, cut away a few inches from the tops as soon as the first flowers open. As the practice involves considerable loss, its general adoption is not advised. A good mulch of manure or lawn mowings laid along the sunny side of the row during very hot weather will keep the roots moist, and economise time in watering.

Varieties :—*For Earliest Sowing.*—Clibran's Masterpiece, English Wonder, Harbinger, Hundred-Fold, Laxtonian, Little Marvel, Peter Pan, Pioneer, Primo.

Second Early.—Duchess of York, Duke of Albany, Duke of York, Essex Star, Gradus, Marrow, Senator, Stourbridge Marrow, Stratagem, The Daisy, The Jap, The Lincoln, World's Record.

Main Crop.—Essex Wonder, Eureka, Glory of Devon, Hercules, Lancastrian, Passport, Peerless, Superlative, and The Bell.

Late Crop.—Autocrat, Dreadnought, Late Queen, Michaelmas, Ne plus Ultra, Rearguard, and The Gladstone.

Large Pods.—Centenary, King George, Quite Content, and Victory.

F. R. C.

NEW VARIETIES.[1]

Good Indeed.—A maincrop sort with large, plump, long pods, containing 8–11 very sweet peas. It is an excellent cropper, and averages 5 ft. in height.

Lord Kitchener.—A first early sort, with long pods containing 8–10 peas of splendid flavour. It matures quickly, and is of robust growth, averaging 3–4 ft. in height.

Old England.—A maincrop sort, with long and large pods containing about nine peas of very sweet flavour. It is excellent for exhibition, and grows 4½–5 ft. in height.

President Wilson.—A second early variety, with large pods containing 8–10 peas of the finest quality. It is very prolific, and of vigorous habit, growing about 2 ft. high.

Sharpe's Liberty.—A late maincrop variety, bearing large, curved, long pods, mostly in pairs, each containing 8–11 peas. It grows about 4 ft. high.

Sharpe's President.—A maincrop variety, with large, curved, dark green pods, mostly in pairs, and each well filled with superior quality peas. It is a heavy cropper, of sturdy and branching habit, growing about 3 ft. high.

Sutton's Amateur's Pride.—A second early variety, with large pods containing 8–11 peas of the best quality. It is almost mildew proof, and is very robust, growing 5–6 ft. in height.

The V.C.—A second early variety, and quite the largest podded pea yet in cultivation.[2] Some of the pods grow to 8 ins. long, and contain 12–13 peas. It is excellent for exhibition, alike a strong grower and very prolific. Its height averages 5–6 ft.

PEAS AND BEANS: SAVING SEED OF. See under VEGETABLES in *SEED SAVING.*

PEAT.

For Rhododendrons, Azaleas, Ericas, and other hard-wooded plants, peat is essential, whether they are grown out of doors or in pots. It should be bed peat if got from the moors, and heath mould if got from heaths and commons. Bed peat is very different from bog peat; the latter is fully charged with water and poisonous vegetable acids, and should never be used.

When using peat for the formation of new borders for the three above-named plants, do not put it on in great lumps and turn these in. Chop the peat up and mix it with half its own volume of semi-rotted stable manure, and dig the mixture in freely, as you would in the case of ordinary manure. Established bushes can also be mulched with chopped peat.

When using peat as an ingredient of potting soils, rub it through a ½-inch sieve and mix thoroughly (see *COMPOSTS*). As peat absorbs water readily, that which is intended for composts should be stacked under cover to protect it from rain.

Peat is also useful for certain rock plants, and plants popularly known as American plants. Readers are referred to separate articles dealing with these subjects.—E. T. E.

PEAT-LOVING ROCK PLANTS.—See ROCK PLANTS REQUIRING PEAT in *ROCK PLANTS FOR ALL PURPOSES.*

PEAT-MOSS LITTER.—See *HORSE MANURE.*

[1] With the exception of *The V.C.* all the varieties are wrinkled.—EDITOR.

[2] These notes were written in November 1919.—EDITOR.

PECAN (*Carya olivaeformis*). — See *TREES*.

PEGANUM.—See *SYRIAN RUE*.

PEGGING-DOWN: ROSES FOR.—See under ROSES FOR PEGGING-DOWN in *ROSES FOR ALL PURPOSES*.

PEGOMYIA.—See BEET FLY in *INSECT PESTS*.

PELARGONIUMS (Nat. Ord. Geraniaceæ). — Florists' section, greenhouse herbaceous perennials, 1–2 ft. high, succeeding in a compost of fibrous loam, leaf-mould, and a little rotten manure. They are propagated by cuttings, the raising of seedlings being practically left to specialists.

Culture. — Cuttings should be chosen from well-ripened shoots in August or September, and inserted in sandy soil in pots or boxes where they will soon root if kept close for a week or two. In a month or six weeks they are ready for removal, and should be set singly in small pots in which they are wintered. Little water is required during this period, but they should not be coddled too much, or the plants will become spindly and weak.

The old Show or Fancy Pelargoniums have almost gone out of cultivation, the modern Florists' Pelargoniums belonging to the Zonal and Regal sections. The former are used both for summer bedding and for greenhouse decoration, the latter almost exclusively as greenhouse plants. Both species flower over a long period, and with proper treatment bloom can be had throughout most of the year.

Varieties:—*Zonal.*—General Joffre, Henry Jacoby, Lady Curzon, Lady Warwick, Mauretania, Maxime Kovalesky, Mrs Brown Potter, Mrs Robert Cannell, Paul Crampel, Phyllis, Snowdrop, The Sirdar.

Regal. — Attraction, Bridesmaid, Dairymaid, Duchess of Teck, Edward Perkins, Exmouth Rival, Loveliness, Magnificent, Market Favourite, Martha Bouchier, Mrs W. J. Godfrey, Ruby Acquisition.—J. L. G.

NEW VARIETIES.

Pelargonium crispum variegatum.—A variegated sport with densely arranged grey-green, silver-margined leaves, and a compact habit. The flowers are inconspicuous.

P. Whiteknights's Glory.—A new Zonal, bearing large trusses of single orange-salmon flowers. It is splendid for bedding.

PELARGONIUMS FOR CITY GARDENS. See under BEDDING PLANTS in *TOWN AND CITY GARDENING*.

PELLÆA.—For the best species see *FERNS AND FERN GARDENING*.

PELLITORY.—See *PARIETARIA*.

PEMPHIGUS.—See LETTUCE ROOT APHIS in *INSECT PESTS*.

PENICILLARIA.—Now included in the genus *PENNISETUM*.

PENNISETUM (Nat. Ord. Gramineæ).—This is a genus of annual and perennial grasses not quite hardy. The best species, *P. longistylum*, known to florists as PLUME GRASS, is referred to in our article on *ORNAMENTAL GRASSES*.

PENNY CRESS. — See *CRESS* and *THLASPI*.

PENNYROYAL, or PENNY-ROYAL (*Meniha Pulegium*).—See *MENTHA* and *POTHERBS*.

PENNYWORT.—A name applied to *COTYLEDON* and *HYDROCOTYLE*, which see.

PENTSTEMONS[1] (Nat.Ord. Scrophulariaceæ). — Hardy herbaceous perennials, 2½–4 ft. high, requiring slight protection in the north and colder parts of the country. They succeed in light sandy loam, mixed

[1] These are sometimes known by the name of BEARD TONGUE.—EDITOR.

with leaf-mould and old manure, and are propagated by cuttings and seeds.

Culture.—Named varieties are increased by cuttings of well-ripened side growths in autumn. These are wintered in a frame or cold house, and planted out in spring. Stronger plants and better blooms are secured by annual propagation. Plants are also easily raised from seed sown in light soil in the spring.

USES.—Pentstemons hold a foremost place amongst bedding plants and are remarkably handsome used in bold clumps in the herbaceous border. The best results are obtained in light and warm soils, such as well-drained loam or chalky formations. The flowering season is early July till the first frost spoils the blooms.

Varieties.—Barbara Hope, Crimson Gem, Diadem, Harold Carey, King George V., Lady Sybil, Leonard Cutbush, Mrs A. C. Sweet, Newbury Gem, President Carnot, Rajah, Seagull, Southgate Gem, Virgil, and White Newbury Gem.—J. L. G.

[The two species *Pentstemon barbatus* and *P. centranthifolius*, both of which used to be included in the genus *CHELONE*, on which we devote another article, are also worth growing. Their scarlet and orange-scarlet flowers are produced freely from July onwards, and the height varies from a yard upwards.—EDITOR.]

PENZANCE BRIARS. — See under HYBRID SWEET BRIAR ROSES in *ROSE CLASSES*.

PEONY.—See the genus PAEONIA in *SHRUBS*. See also *PAEONY*.

PEPPER CRESS (*Teesdalia nudicaulis*, Syn. *T. Iberis*. Nat. Ord. Cruciferæ).—This is too weedy an annual for general culture, but may be sown in the wild garden, when it will flower in May or June, and grow about 3 ins. high.

PEPPER SAXIFRAGE.—See *SILAUS*.

PEPPER TREE.—The genus CLETHRA, especially *C alnifolia*. See *SHRUBS*.

PEPPERIDGE (*Nyssa sylvatica*).—See *TREES*.

PEPPERMINT (*Mentha piperita*).—See *MENTHA* and *POTHERBS*.

PERCENTAGES. — See *ARITHMETIC AND GARDENING*.

PERENNIAL CLIMBERS. — See *CLIMBING AND TRAILING PLANTS*.

PERENNIAL FLAX (*Linum perenne*). See *LINUM*.

PERENNIAL HONESTY (*Lunaria rediviva*).—See *HONESTY*.

PERENNIAL, THE USEFUL: Why it should be more grown.—In the course of my wanderings during a recent holiday in North Wales, I was able to visit several interesting gardens, and many more though not actually visited were admired very much in passing. But although one of the big gardens over which I was taken by the head gardener had extensive perennial borders, the leading feature of most of the other gardens I visited was annuals. Annuals were in the beds and borders, in the window-boxes, and in tubs; they reigned entirely on more than one biggish piece of rock garden; in fact, there was so great a use of annuals that one got tired of them.

Of course annuals are many of them very beautiful things, and there is much to say in praise of them, but after all they last only one season, and all the work has to be done again next year if good effects are to be produced. Annuals cannot usually be left to seed themselves, and if they could the seedlings would come up much too thickly, so they must be sown again next April. If the weather is good they come up in shoals, but if not, bare patches result, which later on are rather difficult to fill in. Annuals

entail a lot of work, and considering they only last a season, it is to my mind a great mistake to grow them too extensively, for I do not think they are worth it.

The present article is in praise of the perennial. I have seen some really grand masses of colour produced by the use of perennials entirely, so also, I expect, have some of our readers, and I am quite convinced that one good perennial colour border is worth two borders of annuals. A perennial border looks so much more "solid" than one containing annuals only, for the perennial plants, if they are two or three years old, are far bigger and give much more massive effects than it is possible to get with annuals alone. Colour borders on a small scale are, of course, not as possible with perennials as with annuals, for obvious reasons, but where there is space and room it is bad policy to my mind to waste the time by trying to make huge colour borders with annuals. Perennials need ample space for good colour effect, and this space many gardeners will be able to give them.

The obvious reason why perennials should be grown more is that of economy. A perennial border when once planted will last for years, and give most beautiful effects if the plants are thinned and the soil dug up and well manured now and again. Most perennials are strong and stand drought well enough, but this cannot be said of annuals. Perennials, of course, do need staking, and so do annuals, but a good many of them which do not exceed 2–3 ft. in height need not be staked much. This cannot be said of annuals. Nearly all annuals of any height require most careful staking, for annuals are more delicate and "flimsy" subjects than perennials.

It may be said that certain delicate perennials greatly resemble annuals in the above respect, but I reply: "Don't grow delicate perennials unless you have much time and patience to give them." Colour borders containing a lot of delicate perennials are seldom a pleasure to behold.

Annuals are very beautiful indeed, but require a lot of care, and are at the outset hardly worth it where time, labour, and expense are considerations. Annuals should only be grown by those who have plenty of time on their hands or who wish to study and describe these interesting plants. It is the perennial which should be popular, the perennial which should be grown first and the annual second, for it is only with the perennial that colour borders can be planned on a really large scale.—E.

PERENNIAL WALLFLOWER. — See *ERYSIMUM.*

PERENNIALS FOR ALL PURPOSES. There is practically no limit to the uses of hardy perennials for the beautifying of the garden, the embellishment of the conservatory, or for decorative purposes in a cut state. There are hundreds to choose from, which is confusing to the beginner, hence we give below a few selections.

Perennials for Bogs.—Amateurs often wonder what perennials to plant in very moist soils or by the water-side. We recommend the following: Acanthus in variety; Acorus in variety; Artemisia in variety; *Arundo Donax;* Asphodels in variety; Astilbes in variety; Bamboos in variety; *Caltha leptosepala,* and *C. palustris fl. pl.; Cardamine pratensis fl. pl.; Carex* in variety; Cimicifuga in variety; *Cortaderia argentea; Crinum longifolium; Cypripedium spectabile; Dactylis glomerata* var. *variegata;*

Dodecatheon in variety; Echinops in variety; Elymus in variety; Epilobium in variety; *Erianthus Ravennae;* Eulalia in variety; Ferns in great variety; Funkias in variety; *Glyceria aquatica* in variety; *Gunnera manicata,* and *G. scabra* (Syn. *G.chilensis*); *Helonias bullata;* Hemerocallis in variety; Heracleum in variety; *Iris Kaempferi, I. germanica, I. orientalis, I. Pseudacorus,* and *I. sibirica; Juncus effusus aurea striata, J. e. spiralis;* Liatris in variety; Lythrum in variety; Mimulus in variety; Monardas in variety; *Myosotis palustris; Narthecium ossifragum; Parnassia caroliniana,* and *P. palustris; Phalaris elegantissimum; Phragmites communis aureus; Physostegia virginiana* (Syn. *Dracocephalum virginicum*); Polygonum in variety; Primula in great variety; *Ranunculus aconitifolius fl. pl., R. amplexicaulis,* and *R. parnassifolius; Rodgersia Æscutifolia, R. podophylla, R. pinnata,* and *R. alba;* Sarracenia in variety; *Scirpus lacustris;* Solidago in variety; *Spigelia marilandica;* Spiraea in variety; *Stipa Calamagrostis, S. elegantissima,* and *S. pennata;* Tradescantia in variety; and Trollius in variety.

Perennials for Borders.—More perennials are available for this than for almost any other purpose. The most suitable for ordinary soils and situations *over three and a half feet in height* are Acanthus in variety; Aconitum in variety; *Anchusa italica Dropmore* and colour sports *Opal* and *Picotee; Anemone japonica* in variety; Asphodelus in variety; Asters (Michaelmas Daisies), such as *A. cordifolius, A. ericoides, A. Novae Angliae, A. Novi Belgii,* and *A. vimineus,* all in their numerous varieties; *Bocconia cordata* and *B. microcarpa; Calystegia hederacea* and *C. pubescens* (Climbers); *Campanula alliariaefolia, C.celtidifolia, C.lactiflora, C. persicifolia,* and *C. pyramidalis;* Centaurea in variety; *Chrysanthemum maximum* in its lovely varieties, as well as *C. uliginosum; Crambe cordifolia;* Delphinium (Perennial Larkspur) in variety; Doronicum in variety; *Echinops Ritro;* Eremurus in variety; *Galega officinalis; Helenium pumilum magnificum,* and other varieties; *Helianthus laetiflorus, H. multiflorus,* and *H. rigidus,* all in their numerous varieties; Heliopsis in variety; Kniphofia (Tritomas, Torch Lilies) in variety; *Papaver orientale* in variety; *Romneya Coulteri* (Californian Poppy); *Rudbeckia laciniata* in variety; and Verbascum in variety.

Perennials *under three and a half feet* and *over eighteen inches* include amongst others Achillea in variety; *Anchusa Barrelieri* and *A. myosotidiflora;* Aquilegias in variety; *Aster Amellus* in variety, including its garden hybrids; Astilbe in variety; *Centaurea montana* in variety; Centranthus in variety; *Chrysanthemum maximum* in variety; *Dicentra spectabilis; Dictamnus Fraxinella* in variety; *Echinacea purpurea;* Eryngium in variety; Gaillardia in variety; Geraniums in variety; *Geum coccineum* in variety; *Gypsophila* in variety; *Helenium Hoopesii;* Hemerocallis (Day Lilies); *Hesperis matronalis fl. pl.* (double Sweet Rockets); *Incarvillea Delavayi;* Inula in variety; *Iris germanica* in variety, as well as *I. Kaempferi, I. orientalis* and garden hybrids; *Lychnis chalcedonica* in variety; *Malva moschata; Monarda didyma* in variety; *Paeonia chinensis,* European double and single forms; *Pentstemon barbatus* in variety; *Phlox paniculata* in variety; Polygonum in variety; Potentilla in variety; *Scabiosa caucasica* in variety; Spiraea in variety; Thalictrum in variety; Trollius in variety; and Veronica in variety.

Perennials *under eighteen inches* in height include Anemone in variety; *Anthemis cupaniana;* Anthericum in variety; *Aquilegia glandulosa* and *A. Stuartii; Arabis albida* (single, double, and variegated forms); Armeria in variety; *Asclepias tuberosa;* Asperula in variety; *Aster alpinus* in variety, and *A. diplostephioides;* Astrantia in variety; Aubrietia in variety; Campanula (dwarf varieties); *Coreopsis oculata;* Erigeron in variety; *Gentiana acaulis* and *G. verna;* Geum in variety; Gypsophila in variety; Heuchera in variety; *Iberis sempervirens* (Perennial Candytuft); *Iris pumila,* and several other species; Lychnis (many dwarf varieties); Meconopsis in variety; *Nepeta Mussini;* Œnothera in variety; *Papaver nudicaule* (Iceland Poppies) in variety; Pentstemon in variety; Phlox in variety; *Polemonium caeruleum variegatum,* and *P. humile* (Syn. *P. Richardsonii*); *Polygonum affine;* Primula in variety; Ranunculus in variety; Veronica in variety; *Viola cornuta* in variety, and Viola (Tufted Pansies) in variety.

Perennials for Conservatories.—If we include cold greenhouses in this section there are many hardy perennials for this purpose which will give results far out of proportion to labour or cost they incur. Some of the best comprise: *Anchusa italica Dropmore; Anemone japonica* in variety; Antirrhinum in variety; Aquilegia, preferably Veitchii hybrids; Asters, or Michaelmas Daisies (the small-flowering section are particularly effective); Astilbe (Arendsii hybrids for choice); *Campanula persicifolia,* and *C. pyramidalis; Dicentra spectabilis;* Heucheras; *Lavatera Olbia;* Pentstemons, Phloxes, Polyanthus, and Verbascums (especially the large-flowering hybrids).

Perennials for Cutting.—The best hardy perennials for this purpose include *Achillea Ptarmica The Pearl* and *A. decolorans; Asperula hexaphylla; Chrysanthemum maximum* in variety; *Gaillardia grandiflora* in variety; *Gypsophila paniculata,* and its double counterpart; Heucheras in variety; *Lupinus polyphyllus,* and *L. arboreus; Papaver orientale,* and *P. nudicaule* (Oriental and Iceland Poppies); Phloxes, all varieties; Pyrethrums, all varieties, single and double; *Scabiosa caucasica* in variety; and *Thalictrum rugosum.*

For hints on cut flowers see our articles on *Flower Gathering* and *Flowers for Indoor Decoration.*

Perennials for Hot, Dry Soils.—We suggest the following: Achillea in variety; *Alyssum saxatile* in variety; *Antennaria dioica* (Alpine Everlasting); *Arabis albida* (single, double, and variegated forms); Aubrietias in variety; *Armeria latifolia* (lilac, white, and pink); Cheiranthus in variety; Cistus in variety; Dianthus in great variety; Dracocephalum in variety; *Erodium chrysanthum, E. guttatum, E. hymenodes,* and others; Eryngium in variety; Geranium in variety; Gypsophila in variety; Helianthemum in variety; Hypericum (single and double sorts); Iberis (Perennial Candytuft) in variety; Linaria in variety; Linum in variety; *Lupinus polyphyllus* in variety, and *L. nootkatensis; Nepeta Mussini; Plumbago Larpentae; Polygonum vaccinifolium;* Sedum, all varieties; Sempervivums, all varieties; *Saponaria ocymoides;* Thymus in variety; and *Verbascum phoeniceum* in variety.

Perennials for Rock Gardens.—There are hosts of these, but some of the best include: Æthionema in variety; Alyssum in variety;

Anemone in variety; Antirrhinums in variety; *Aquilegia alpina;* Arabis in variety; Arenaria in variety; *Aster alpinus;* Astragalus in variety; *Callirhoë involucrata;* Campanula in variety; *Cerastium Biebersteinii,* and *C. tomentosum; Cheiranthus alpinus;* Coronilla in variety; Corydalis in variety; Dianthus in variety; Draba in variety; Erigeron in variety; *Erinus alpinus; Erysimum rupestre;* Geranium in variety; Geum in variety; Globularia in variety; Gypsophila in variety; Helianthemum in variety; Heuchera in variety; *Hutchinsia alpina;* Iberis in variety; *Leontopodium alpinum* (Edelweiss); Linaria in variety; Linum in variety; *Lippia repens; Lotus Siliquosus;* Lychnis in variety; Meconopsis in variety; *Michauxia campanuloides;* Mimulus in variety; Myosotis in variety; Œnothera in variety; Ononis in variety; *Papaver alpinum* and *P. nudicaule* with their varieties; *Phuopsis stylosa; Phyteuma orbiculare;* Platycodon in variety; *Polemonium confertum* and *P. reptans;* Potentilla in variety; Primula in variety; *Saponaria ocymoides;* Saxifraga in variety; *Scutellaria alpina;* Silene in variety; Statice in variety; Tiarella in variety; *Tunica Saxifraga; Verbena Chamaedryoides;* Viola in variety; and *Vittadenia triloba.*

Perennials for Old Walls.—A few of the best include: *Achillea tomentosa; Alyssum saxatile;* Antirrhinum in variety; Arabis in variety; Arenaria in variety; Campanula in variety; Centranthus in variety; Cheiranthus in variety; *Coronilla minima; Corydalis lutea;* Dianthus in variety; *Draba aizoides; Erinus alpinus;* Erodium in variety; Gypsophila in variety; Helianthemum in variety; *Hutchinsia petraea;* Iberis in variety; *Linaria Cymbalaria;* Lychnis in variety; *Santolina lanata; Saponaria ocymoides;* Saxifragas in variety; Sedums in variety; Silene in variety; Thymus in variety; *Tunica Saxifraga fl. pl.;* and Veronica in variety. See also articles on *North Borders* and *Shady Borders.*

Perennials for Town Gardens.—The following are a few of the many suitable subjects: Aconitums, Agapanthus, Anemones, Asters, Aubrietias, Auriculas, Campanulas, Chrysanthemums, Delphiniums, Dianthus, Ericas, Gaillardias, Geums, Heleniums, Helianthus, Hemerocallis, Hollyhocks, Hypericums, Iris (particularly the "Flag" section), Kniphofias or Tritomas, *Lathyrus grandiflorus,* Linarias, Linums, Lychnis, *Lupinus polyphyllus* and *L. arboreus,* Montbretias, Pansies, Papavers (Oriental and Iceland Poppies), Pentstemons, Phloxes, Physostegias, Polygonums, Primulas, Pyrethrums, Rudbeckias, Solidagos, Statice, Tradescantias, Verbascums, Veronicas, and Violas.

Perennials for Under Trees.—A large number are available, of which the following are some of the best: Ajuga in variety; Anemone in variety; Astrantia in variety; *Cardamine pratensis fl. pl.;* Corydalis in variety; Cyclamen in variety; Cypripedium in variety; Dodecatheon in variety; Epimedium in variety; Euphorbia in variety; Ferns in great variety; Funkia in variety; Gaultheria in variety; Helleborus in variety; Hepatica in variety; *Horminum pyrenaicum; Lysimachia Nummularia; Meconopsis cambrica; Mertensia sibirica; Polygonum affine; Saxifraga cordifolia, S. umbrosa; Sedum spurium;* Thalictrum in variety; *Tiarella cordifolia, T. unifoliata; Trillium grandiflorum;* Vinca in variety; and *Waldsteinia trifolia.* Jno. Ha.

PERENNIALS: GENERAL CULTURE OF.

Hardy Perennials and indeed Half-Hardy Perennials are of such immense importance nowadays that an article on the general culture of them is called for in this Dictionary. It is not sufficient now for the gardener to get roots of various Perennials to plant in his borders in the spring or autumn when he wishes to increase his collection. It is not enough either for him to beg divisions or slips from his friends. He must be acquainted with the methods of growing them for himself, from the earliest stages to the time when they come to their best, namely, at the end of a period of three years.

It is very interesting work, the raising of Hardy Perennials from seed. To think that the tiny seeds which many of them possess, are capable of growing into enormous plants 6–8 ft. high, covered with bloom of some of the most entrancing colours, makes one wonder at the power of Nature, who can do what seems impossible at the start. The tiny seeds first grow into seedlings, which the gardener must take care of, then into first-year plants, which endeavour to flower, but this must be stopped; then into second-year plants, which may be allowed to produce one or two spikes of bloom — these should be cut off immediately for use in the home; and last of all into three-year plants, from which masses of bloom can be cut week by week throughout the flowering period.

HARDY PERENNIALS.—First of all, then, let us speak about the culture of Hardy Perennials and give attention towards the end of our article to the culture of the less hardy species. There is nothing to fear as regards the difficulty of growing Hardy Perennials. Most of them are of extremely easy cultivation, though naturally in the seed stages they require care. Damp is the great enemy of the seedlings, but precautions must be taken against it. Slugs and snails are among the chief enemies, but these can be got rid of by using a soil fumigant or one of the patent slug and snail traps.

Sowing the Seed.—Seed of Hardy Perennials is best sown either out of doors in a lightly shaded spot, or in a cold frame from June 1st to June 15th. The soil should be so light that at least one-quarter of its volume is sand, since, if it is too rich, the seedlings will not be of the short, sturdy nature which every gardener requires. If the rich soil be used, they will be tall, soft, and sappy. They will look well, it is true, but they will not do well.

Very shallow drills are taken out with a pointed stick, and these drills should be at least 6 ins. apart. For small seeds the depth should not be more than one-third of an inch, but larger seeds may be buried 1 in. or slightly more. Should the soil be dry at the time, the seed-bed should be thoroughly well soaked with warm water the night before. It will then be in an almost ideal state for sowing the following morning.

As is the case with all seeds, strong plants cannot be expected if thick sowing is adopted. Thick sowing means small, spindly seedlings of a stunted appearance, which will do no good at all, and these might as well be scrapped at once. Thin sowing produces strong, short,

sturdy, many-branched seedlings, which are a pleasure to look at, and which are all that can be desired. So bear in mind when you are setting the seed of Hardy Perennials to sow it extremely thinly, and if you cannot trust yourself to do this direct from the packet, mix the seed with ten or even twenty times its volume of fine sand, and sow the mixture very thinly along the drill.

It is obviously a necessity that each drill should be devoted to a separate class of plant. At the end of each drill should be put a painted label with the name of the plant and the date on which the seed was sown. This serves as a guide for the gardener, and at any rate he knows what his plants are when they appear. It does not do to trust to memory, since memory frequently fails on just the very matters which one wants to retain in one's mind.

Having sown the seed, if it is very small, cover it lightly with soil that has been passed through a very fine riddle, otherwise the soil from the drill may be drawn back, and the seed covered with this. Give a slight watering through a fine-rosed can, put on the lights if a frame is used, and leave Nature to do the rest.

As soon as the seedlings appear it is essential that air should be given. Should the weather be unduly hot, it is advisable either to paint the glass of the frame over with some kind of lime-wash, or to shade it with tiffany mats during the hottest part of the day. The latter is preferable since it can be removed or put on at will. If the plants are sown out of doors, it may be necessary to stretch black cotton over them to prevent the birds from pecking the seeds or seedlings as they appear. Some kind of shade will again be necessary if the seed-bed is unfortunately placed in the hottest part of the garden.

Pricking Out.—When the plants are about a couple of inches high, which should be within thirty days of sowing in most cases, it is essential that the bed for pricking them out shall be prepared without delay. Instead of putting this in a shady part of the garden, the writer favours its preparation in the sunniest possible spot, since strong growth is advisable at this stage, and not lanky growth, which is produced by seedlings being drawn in a shady spot in their effort to reach the sunlight. The site intended should be thoroughly well dug, and some old hotbed manure or, better still, cow manure, which is at least two years old, should be dug in, not more than 9 ins. deep. If some burnt wood ashes from the garden fire can be spared, dig these in, at the rate of two ounces or more per sq. yard, and a dressing of old soot sufficient to blacken the surface of the soil very thoroughly will, if forked in, do much to keep down harmful pests which may otherwise prove troublesome. Should soot not be available, a mixture of one part Naphthaline to fifteen parts of Quicklime may be forked in fairly generously, so long as the bed is prepared ten days prior to pricking off.

The actual work of pricking off must be done with some care. The seedlings are lifted from the seed-bed, or seed-drills, as we had better call them, with a small hand-fork. Each plant is separated without breaking its roots, and the pricking off, instead of being done with a dibber, which instrument necessitates the roots of the plants being doubled up in a hole very much too small for them, instead, I say,

of doing anything so foolish as that, the little plants should be set singly with a trowel, in holes large enough for them, and in such a way that their roots just touch the bottom of these holes. They should be made very firm. Should the plants be exceptionally strong it will be advisable to set them about 9–10 ins. apart each way, putting the plants alternately in the rows, so that any given plant is opposite to the space between two others in the row above or below. If the plants are not exceptionally strong, 6–7 ins. apart each way will be more than sufficient, but again, if the gardener's hoe has a blade 5 ins. wide, a distance of 6 ins. between the rows will not be sufficient to allow for the use of the tool.

Should the pricking out have to take place in exceptionally dry weather extra precautions must be taken. The plants should have a thorough soaking of water the night before, in which one quarter of an ounce of Sulphate of Ammonia or Nitrate of Soda has been dissolved in each gallon. This will serve to encourage them to face the check they are to receive on the day following. The site itself, if the soil be dry, should be thoroughly well soaked with water the night before, and if the Clerk of the Weather wills that a particularly hot July day shall come just when you wish to prick out your plants, it may be advisable to rise from your bed an hour sooner and give the site another soaking of water in the early morning. By the end of the afternoon the bed in which they are to be pricked out should be in a decent condition for the work, but on no account must it be made so wet that it is pasty, for no new roots can grow in mud. Firm planting is absolutely essential, and the soil must thus be in just the right state for the work.

After pricking out, give a thorough good watering, and should there be any fear of pests lurking about, a thorough good dose of old soot will be advisable, while the plants are still wet. The after culture during the first summer consists of frequent hoeing and watering when the soil becomes dry. It is inadvisable to feed them with any liquid manure at this stage, save perhaps an occasional dose of soot water. The writer is quite aware that seedling perennials are usually dosed with all manner of concoctions, patent and otherwise, during the first few months of their growth, but he considers that the freaks which are seen, not to speak of the appalling specimens which are sometimes planted into Herbaceous Borders, are due largely, if not completely, to this very grave error in cultivation.

Care in the Winter.—It now becomes necessary to pay some attention to the important matter of the care of these young plants in the winter. Of course, the first winter is to be feared most, but the second winter is not without its dangers, and it is easy to lose a valuable collection if care is relaxed when the plants are some fifteen or sixteen months old. Winter care is thus almost more important than that lavished on the plants in the summer; but it is well to point out at this juncture that, if bad cultivation is adopted in the summer, the plants are far more likely to die during the winter, however much care is bestowed upon them. But if the plants are strong, sturdy stuff, with short, stumpy growth and plenty of joints, without any of the soft, sappy appearance which is all too common, then they can reasonably be expected to withstand the winter, even if they must remain out of doors.

Should it be your fate to live in a very exposed district where winds blow straight from the fells or the moors, where snow and sleet are of almost daily occurrence during the months of December, January, and February, and where the thermometer frequently registers twenty degrees of frost, then it would be well not to risk leaving the first-year or even second-year plants out of doors during the winter. They might come through perfectly well, but, on the other hand, there is a grave risk of losing the lot, and it is better in this case to arrange a rough frame in a southerly position in the garden. Lift the plants in October and set them fairly close together in light sandy soil or even in ashes, labelling each row carefully to avoid confusion next spring, and then put on the lights and leave them on throughout the winter, except on days when ventilation can safely be done without the thermometer registering anything below 36° F. In this case it is advisable that the position selected be a dry one, where there is plenty of drainage, or damping off is almost certain to take place.

If, on the other hand, you live in a genial spot where you only have to face an average winter, there is no need for anything so obviously tiresome as lifting of the plants either in the first year or in the second season. Instead of lifting them, the dead growth after frost has come should be cut off, and little mounds of ashes put over each crown in such a way that the rain will run off. These little mounds are removed in the month of March, and it will be found that the plants are already beginning to grow at that time, and will come through the winter perfectly safely with that treatment. It is advisable to do this both for the first and the second years in order to ensure thoroughly strong plants for the borders during the third season.

Some writers favour the use of half-rotted leaf-mould or cocoanut fibre refuse for the purpose just mentioned, but anything of a vegetable origin seems to the present writer to be fraught with a certain amount of danger. Although such material as cocoanut fibre may seem very innocent in itself, the fact remains that it is of vegetable origin, and is thus capable of fermenting. Should it start to decompose in contact with the crowns of these plants, in nine cases out of ten it would decompose them also, and when it was raked off in the spring of the year, there would be nothing left but lifeless pieces of rootstock in each case.

Planting Out.—The writer is quite aware that most gardeners would plant perennials out in their permanent positions in the Herbaceous Border some seventeen or eighteen months after the seed was sown, namely, during the second year of their growth. This seems to be quite a mistake on consideration. It never pays, for the plants cannot have the individual attention once they are in the border that they would receive in any less permanent position. So, despite all that may be said in favour of planting out permanently in the spring of the second season, all gardeners are advised to leave the plants where they are until the autumn of the second season or until the spring of the third season. This will ensure their being really strong when they are planted out, and results will be far better than they would otherwise be.

As regards the preparation of the ground for planting out permanently, this is dealt with under *Herbaceous Borders*. The same remarks apply

to after cultivation, such as tying up, hoeing, cutting the flowers, and so on, which are all dealt with in that article, and are referred to in other articles as well, as, for instance, in the article on *Stakes and Staking*. Care must be taken even in the third year to protect choice plants from the ravages of pests by dusting with lime or soot, and so on, and the choicer plants, especially if the district is exposed, should be protected by a mound of ashes over their crowns in the way just described.

Culture by Division.—A word must be said in conclusion as to the general culture of perennials by means of division. Now division of the rootstock means more than merely chopping a clump into four pieces with a sharp spade. True, it is the course most usually adopted, and unless care be taken, plants can be utterly spoiled by this rough method of treatment. A carving knife is a far better tool than a spade to use, and the sharper and older it is, the better.

The best time to propagate by division is in the autumn or early spring. The clumps are lifted with as much earth as possible on them, and cut in such a way that the strong outer portions are retained, and the weak or often dead pieces are rejected. The clumps are then re-planted in good soil in the border, and should do very well, even during the first season, after this ordeal.

It is well to note that such plants as Lupines will not propagate easily by this method. Much the same applies to Anchusas, though these are not quite so difficult as Lupines. Where there is difficulty in increasing by division of the roots, it is best to raise stock by seed every third or fourth year and have a batch of plants constantly following on.

There is another mode of culture which is allied to division. This is propagation by means of root cuttings. Early flowering perennials always throw up a lot of young growth within a month after they have finished flowering, and if this is cut off by, or just under, the ground line, it very often has roots already attached to it, so that each shoot is really a little plant.

To propagate by this means is thus easy. A sharp knife is used to sever the shoots from the parent plant, and these are pricked out, or rather planted with a trowel in a bed of light sandy soil in a site not too sunny. The distance apart will, of course, vary with the nature and size of the plant, but at any rate it should not be less than 6–7 ins. each way. Frequent hoeing and frequent watering immediately after, and during the three months following the ordeal, are the secrets of success.

As regards stimulating these young plants, far the safest liquid to use is soot water. They can have constant soakings of this liquid, and will be mildly stimulated as well as protected from the ravages of a great number of pests. Plants increased by this method may be set in their flowering positions the same autumn or the following spring, but they must not be allowed to do much during the first season.

Throughout the whole general culture of Hardy Perennials it is immensely important to keep the beds thoroughly hoed and weeded. The very act of hoeing stimulates the growth and kills enormous numbers of weeds as well as surface pests, and if gardeners realised the vast importance of this work, there would be more success in Perennial Cultivation than there is at present.

Half-Hardy Perennials.—Now that we have dealt more or less

fully with the culture of Hardy Perennials, we must conclude with a few remarks on the culture of the less hardy species, known collectively under the term Half-Hardy Perennials. There are various ways of growing these plants, and one of the most favourite is to adopt a system similar to the culture of Half-Hardy Annuals. To do this, seed is purchased early in the year, and is sown very thinly in boxes of light sandy soil in heat, in January or early February. The boxes are covered with glass, and brown paper is put over the glass to exclude light. As soon as the seedlings appear, the glass and paper are removed, and they are put close to the light on a shelf high up in the greenhouse. This will encourage short, sturdy growth, which is so eminently desirable.

When the little plants are a few inches high, they should be pricked off into other boxes of similar light soil, and brought on with all possible speed, being put close to the glass in the greenhouse. In April and May they are transferred to a cold frame to be hardened off, and by the end of May they should be in a fit state to plant out. Planting out can be done in Herbaceous Borders or in separate beds similar to bedding plants, and care should be taken in each case to plant very firmly. The rest of the culture through the summer is very similar to that of Hardy Perennials, so we pass on to the first winter.

Now Half-Hardy Perennials will not stand out of doors through the winter, so it becomes necessary to lift them about the end of September and plant them close together in boxes of light soil, transferring these to the greenhouse, where a temperature of not less than 45° F. can be maintained. The structure should be ventilated on all possible occasions to ensure the prevention of damp, but the temperature should not be raised unduly, as this is the resting season of the plants. Next spring in May they can be planted out again in their permanent positions and once more lifted the following October. Usually Half-Hardy Perennials do not stand more than the third or fourth season, so it is advisable to have a new stock coming on.

Half-Hardy Perennials may also be sown out of doors in May or June when Hardy Perennials are sown. In this case the culture of the two classes is the same until the autumn of the first season, after which the seedlings of the Half-Hardy sorts must be transferred to a greenhouse. The cold frame is not sufficient protection.

It must be remembered that there are a very large number of plants which are included in the term Half-Hardy Perennials. The great majority of greenhouse plants are Half-Hardy Perennials, but they do not come quite within the scope of this term. When we talk about Hardy Perennials, we mean Hardy Herbaceous Perennials, plants which can be grown out of doors in the borders and die down every autumn. Also, when we speak of Half-Hardy Perennials, we mean Half-Hardy Herbaceous Perennials, plants which are useful for the outdoor garden though they need winter protection. These also die down naturally every autumn, and come up again the following spring. Thus most of the greenhouse plants are ruled out of this category, as the majority of them will continue growing right through the winter months without ceasing, and have not a herbaceous rootstock in the sense of true Half-Hardy or Hardy Perennials.

It must be remembered that, when

there are so many really first-class Hardy Perennials, it is to a certain extent waste of time to grow any large quantity of plants which need greenhouse protection during the winter, and can only be put out in the borders in the summer. Thus Half-Hardy Perennials have not, and never will, it is thought, come to the front as have their hardier brothers of late years, and gardeners must have much leisure and much glass at their disposal if they are to make a success of the cultivation of these somewhat *difficile* plants.—E. T. E.

PERENNIALS, HALF-HARDY : List of.—For the convenience of those interested we think it desirable to give a short list of good Half-Hardy Perennials, including some bulbs and plants of similar nature. The latter are marked *B.* These should be kept dry in winter, and either started under glass or planted out in April or May, except some marked *E.*, which should be put into the ground in March. The others can be wintered in a house where they are kept free from frost, and planted out in May with bedding plants. For cultural details see separate articles on the different sorts.

	Inches
Alstroemeria pelegrina (*B.E.*). White, yellow, and purple. Autumn.	24
Anemotheca cruenta (*B.E.*). Red. Summer.	6
Antholyza aethiopica (*B.E.*). Red and yellow. Autumn.	24

PERESKIA.—A genus of cactaceous plants. See *CACTI.*

PERFUME MAKING.

The extraction of perfume from flowers is an interesting operation. By following the simple plan below, a highly scented oil may be secured that will retain its fragrance for an indefinite period.

Take a good-sized jar and cut a number of rounds of cotton-wool, such as will fit inside the vessel. Then secure a quantity of the finest olive oil, and immerse the pieces of cotton-wool in this until thoroughly saturated. The flowers from which it is desired to extract the perfume should be freshly gathered. By far the best time to pick them is in the early hours of the morning directly after the dew has disappeared. All the green parts of the flowers should be removed, and the larger blossoms, such as roses, picked to pieces. When the flowers have been prepared they may be packed away in the jar, placing one of the oil-soaked rounds of cotton-wool in the bottom first and then scattering on to this, a handful of the petals, at the same time adding a light sprinkling of finely crushed common salt. Then put another of the pieces of cotton-wool on the top, and add another layer of petals with more salt. Proceed in this way until the jar is full. To get a large number of petals into the jars the mass may be pressed down from time to time. Last of all tie a piece of paper over the mouth of the jar and stand it outside in the sun.

At the end of two days the oil will have absorbed most of the perfume of the flowers, and to get as much as possible of it from the cotton-wool, the best plan is to tip the whole of the contents of the jar into a piece of fine muslin. Tie the corners of the material together so that a bag is formed. Get a clean bowl and, into this, press out all the oil that can be squeezed, storing this in tightly stoppered bottles. Some wonderful natural perfumes may be prepared from real flowers in this manner, and not a few will prefer these to the more complicated scents of the manufacturer.

Another interesting way of capturing the fragrance of flowers involves the use of ice. Procure a small glass funnel such as is often used by chemists. The narrow end instead of being open, should be drawn out to a fine point. This may be done by softening the end of the funnel in a gas flame and then closing and shaping the glass into a point. For supporting the funnel a retort stand is useful but, if this cannot be secured, a length of thick wire can be made to serve. Bend the end of this round in a circle in which the funnel will rest. The other end of the wire may be held firmly between two heavy books or boxes. In any case the funnel should be raised sufficiently high to place a glass vessel underneath.

The flowers must be fresh and it is well to carry out the operation in a warm room where the perfume will be freely emitted. In order to prevent the blossoms from fading, place them with their stalks in water. Stand the vase close to the glass funnel and then fill the latter with small fragments of ice. After an interval it will be seen that the moisture from the air is condensing on the outside of the glass funnel and, as this accumulates, it trickles down into the glass vessel below. After the ice in the funnel has melted a further supply may be filled in. When a fair amount of the condensed moisture has been collected this may be examined. It will be found to be deliciously perfumed according to the kind of flower from which the scent has been captured. The fragrant volatile oil of the blossoms has blended with the moisture of the atmosphere which has been condensing on the outside of the funnel. Flower perfume captured in this manner will not keep good indefinitely unless it is blended with an equal quantity of spirits of wine. In this state it may be bottled up for use as required.

S. L. B.

PERILLA.—See *ANNUALS, HALF-HARDY: LIST OF.*

PERIPLOCA.—For the best species see *CLIMBING AND TRAILING PLANTS.*

PERISTERIA.—See *ORCHIDS.*

PERIWINKLE (*Vinca.* Nat. Ord. Apocynaceæ).—Considerable discussion took place a year or two ago as to whether this plant was suitable or not for rock garden culture. We held, and still hold, that it is; others say emphatically no, so readers must form their own opinion. That it spreads very rapidly most gardeners know, but in rock borders and large sweeps of the rock garden this is no disadvantage. If it be used as a carpeting plant in the rock border, rock garden, herbaceous border, or wild garden, it should certainly be kept away from choicer subjects, since it will quickly smother any plants which are somewhat weak. It is excellent for carpeting ground under deciduous trees.

Culture. — Botanically, Periwinkles are hardy and stove evergreens, but the hardy sorts are admissible in the herbaceous border, as they respond to the usual culture for hardy perennials. With the stove species we do not deal in the present work in accordance with our note on *STOVE PLANTS* elsewhere. All the species described below may be propagated by seeds in the summer, division of the roots in November or March, and by cuttings inserted in a shady spot in the spring, while they may be successfully planted any time during the winter.

Border and Rock Garden Species.—We describe a few of the best, most of which grow with remarkable freedom and even thrive under the shade of trees:—

Vinca herbacea (Syn. *V. acutiflora*).—This is a useful sort, bearing purple flowers in June and July. It grows about 1½ ft. high.

V. humilis.—Syn. *V. minor*, which see.

V. major.—This bears blue or purple flowers in July and August, averaging about 2 ft. in height. The variegated variety is pretty also.

V. media.—This is a pretty blue sort, flowering in July and August, and growing about 12 ins. high.

V. minor (Syn. *V. humilis*).—This is quite the most popular but spreading Periwinkle of all. It bears flowers of various shades of purple, lilac, blue, and also white, from June to October, and averages about 6 ins. high. There are varieties of each colour with variegated foliage.

See also *WATER GARDEN: PLANTS FOR THE*, and under VINCA in *SHRUBS.*

PERNETIANA ROSES. — See *ROSE CLASSES.*

PERNETTYA.—For the best species see *SHRUBS.*

PERPETUAL BORDER CARNATION. See *CARNATION: PERPETUAL BORDER.*

PERPETUAL FLOWERING CARNATION.—See *CARNATION: THE PERPETUAL FLOWERING.*

PERPETUAL FLOWERING MALMAISONS.—See *CARNATION: THE MALMAISON.*

PERPETUAL SPINACH, or SPINACH BEET (*Beta maritima.* Nat. Ord. Chenopodiaceæ).—As the name suggests, this is not a true spinach, but the leaves when boiled make a very good substitute. Seed may

be sown on any well-dug soil from early April until the end of August. The plants need about 9–12 ins. each way. Surplus plants bear transplanting better than most things.

If carefully managed, a bed will remain in a profitable condition for twelve months, and give an enormous crop of leaves.—F. R. C.

PERRY'S WEEPING HOLLY. (*Ilex Aquifolium argentea pendula*).—See HOLLY.

PERSIAN ANDROSACE (*Androsace filiformis*).—See ANDROSACE.

PERSIAN LILAC (*Syringa persica*).—See SHRUBS.

PERSIAN RANUNCULUS.—See under TYPES AND VARIETIES in RANUNCULUS.

PERSICARIA.—An annual weed. See WEEDS. The genus PERSICARIA is now included in POLYGONUM at Kew.

PERSIMMON (*Diospyros virginiana*). See TREES.

PERUVIAN GUANO.—See GUANO.

PERUVIAN LILY.—See ALSTROEMERIA.

PERUVIAN SQUILL (*Scilla peruviana*). See SCILLA.

PESTS.—See GARDEN ENEMIES and INSECT PESTS.

PESTS AND DISEASES OF VEGETABLES.—See VEGETABLES: GENERAL CONSIDERATIONS.

PESTS, NOTIFIABLE.—See NOTIFIABLE DISEASES AND PESTS.

PESTS OF CACTI.—See CACTI.

PESTS OF CITY GARDENS.—See TOWN AND CITY GARDENING.

PESTS OF FRUIT.—See INSECT PESTS and ORCHARDS: MAKING AND MANAGEMENT OF.

PETALOSTEMON (Nat. Ord. Leguminosæ).—Two species of this (*P. candidus* and *P. violaceus*), both known by the name of PRAIRIE CLOVER, are worthy of introduction into large herbaceous borders as both are hardy perennials of very easy culture. The first bears white flowers, the second purple or violet-purple. Both bloom from July to August, and average 12 ins. in height.

PETASITES (BUTTER BURR. Nat. Ord. Compositæ).—This is a small but useful genus of hardy perennial plants for the border, rock garden, and wild garden. They thrive with very little care and may be treated in the same way as other hardy border subjects. Propagation by seeds in the summer, and root division in November or February, is a comparatively easy matter, and successful results may be attained by March planting. A selection of the species are briefly described below:—

Petasites albus.—This is a white spring blooming plant growing about 12 ins. high.

P. fragrans.—This is the well-known and popular WINTER HELIOTROPE bearing its white fragrant flowers from November to January. It is useful for the rock garden as it only grows about 9 ins. high, but it spreads rather freely.

P. niveus.—This is a pure white sort blooming in March and April, and growing 12–15 ins. high.

P. officinalis (Syn. *P. vulgaris*).—This, the COMMON BUTTER BURR, sometimes offered as "a desirable pink March blooming subject about 12 ins. high," is really a weed and not worth cultivating.

P. spurius (Syn. *P. tomentosus*).—This is a white April blooming sort about 12 ins. high.

P. vulgaris.—See remarks on *P. officinalis* above, with which this is now considered synonymous.

PETROCALLIS.—Now included in the genus DRABA.

PETROCOPTIS.—Now included in the genus LYCHNIS.

PETROSELINUM.—Now included in the genus CARUM.

PE-TSAI.—A variety of *CHINESE CABBAGE*, which see.

PETTY GRASS (*Chenopodium Quinoa*). See *CHENOPODIUM*.

PETTY SPURGE (*Euphorbia peplus*).—A weed. See *EUPHORBIA* and *WEEDS*.

PETTY WHIN (*Genista anglica*).—See *SHRUBS*.

PETUNIA (Nat. Ord. Solanaceæ). A half-hardy herbaceous perennial, 1–2 ft. high, succeeding in light loam and leaf-mould—not too rich. Propagate by seed sown in heat in March. Named varieties can only be increased by cuttings in the autumn in a warm greenhouse.

Culture.—Prick out early, and pot off the seedlings singly, or, if for bedding, prick out into boxes, harden off, and plant out in May. If for greenhouse culture, grow the young plants steadily on and transfer to their flowering-pots in May.

USES.—Petunias are useful for bedding in hot, dry positions where few other plants would flourish. They are also well adapted for furnishing hanging-baskets, and grow to perfection as pot plants in conservatory or greenhouse. They bloom practically all the summer.

Varieties.—Named sorts are not so much in vogue as they used to be, but choice strains of seed are sold by specialists. The following may be particularly noted: Brown's Purple Strain, Carter's Empress, Carter's New Marbled Purple King, also species such as concordia and hybrids, grandiflora and variegata.—J. L. G.

NEW VARIETY.

Petunia Purple King.—This bears deep violet-purple double flowers.

PEUCEDANUM (HOG'S FENNEL. Nat. Ord. Umbelliferæ).—This is a large but unimportant genus of hardy biennial or herbaceous perennial plants of no value for border culture. The two best known species are *P. graveolens*, the common herb DILL, used for medicinal purposes (see article on *MEDICINAL HERBS*), and *P. sativum*, the WILD PARSNIP, from which the garden parsnip has been obtained (see article on *PARSNIP*). Other species, such as *P. officinale*, the SULPHURWORT, and *P. Ostruthium*, the MASTER-WORT, are alike weedy and useless.

PHACA.—Now included in the genus *ASTRAGALUS*.

PHACELIA (Syns. *Eutoca* and *Whitlavia*. Nat. Ord. Hydrophyllaceæ).—The Phacelias form an interesting group of hardy annuals of lowly growth, and probably a dozen species are in cultivation, but only two or three are at all popular. Seeds should be sown in April and the plants thinned to about 6 ins. apart to obtain the best results. They are most suitable for edging or massing, but should not be handled too freely, as some, notably *P. viscida*, will cause severe irritation on sensitive skins.

Phacelia campanularia. — This bears deep blue bell-shaped flowers throughout the summer. Its variety *caesia* has rosy flowers. Both grow about 8 ins. high.

P. viscida (Syn. *Eutoca viscida*).—This attractive sort bears violet and blue flowers from the early summer to the autumn. Its height is 6–12 ins.

P. Whitlavia (Syn. *Whitlavia grandiflora*). — This bears violet flowers very freely throughout the summer, and grows 1 ft. high.

PHAEOPAPPUS.—Now included in the genus *CENTAUREA*.

PHAIOCALANTHE.—See *ORCHIDS*.

PHAIUS.—See *ORCHIDS*.

PHALÆNOPSIS.—See *ORCHIDS*.

PHALANGIUM.—Now included in the genus ANTHERICIUM.

PHALARIS (CANARY REED. Nat. Ord. Gramineæ).—This is a genus of hardy grasses of little garden value though of very easy culture. *P. canariensis* (CANARY GRASS) is interesting and useful as its seeds are food for canaries and other cage birds. Some people confuse this plant with CANARY CREEPER (*Tropæolum aduncum*). They are, however, quite different subjects.

PHARBITIS.—Now included in the genus *IPOMOEA*.

PHASEOLUS (Nat. Ord. Leguminosæ).—This is a large genus of hardy and tender climbing or twining annuals. The two most important species in this country are *P. multiflorus*, the SCARLET RUNNER BEAN, and *P. vulgaris*, the HARICOT BEAN. See article on *BEANS*.

PHEASANT'S EYE (*Adonis autumnalis*).—See *ADONIS*.

PHEASANT'S-EYE NARCISSUS (*Narcissus Poeticus*).—See *NARCISSUS SPECIES*.

PHEGOPTERIS.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING*.

PHELLANDRIUM.—Now included in the genus *ŒNANTHE*.

PHENOL.—A popular name for CARBOLIC ACID, which see in *ACIDS: THEIR USES IN HORTICULTURE*.

PHILADELPHUS.—For the best species see *SHRUBS*. See also *CLIMBING AND TRAILING PLANTS*.

PHILAENUS.—See CUCKOO SPIT in *INSECT PESTS*.

PHILLYRAEA.—For the best species see *SHRUBS*.

PHLEBODIUM.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING*.

PHLEUM (CAT'S-TAIL GRASS, Nat. Ord. Gramineæ).—This is a genus of hardy easily grown grasses of no great garden value. *P. alpinum*, *P. Michelii*, and some others may be used in the wild garden, and grow about 1 ft. high. *P. pratense*, known as TIMOTHY, and its variety *nodosum* are useful farm grasses on heavy land.

PHLOMIS (Nat. Ord. Labiatæ). This is a genus of hardy shrubs, and half-hardy as well as hardy perennials. We exclude the first two sections as they are not of much importance to gardeners.

Perennial Border Species.—These require nothing more than the usual treatment bestowed on hardy perennials. They succeed in any good rich soil in a sunny site, and are best propagated in the usual way by summer sown seeds or by autumn root division. We recommend the following:—

Phlomis armeniaca.—This bears pure yellow flowers in July, and grows about 1 ft. high.

P. bracteosa (Syn. *P. lamiifolia*).—This bears purple flowers from May to June, and averages 1–2 ft. in height.

P. cashmiriana.—This bears charming lilac flowers from July onwards, and grows about 2 ft. in height.

P. fruticosa[1] (JERUSALEM SAGE).—This is quite the best known and most popular species of all. It bears yellow flowers from June onwards, and grows about 1 yd. in height.

P. lamiifolia.—Syn. *P. bracteosa* above.

P. lunariifolia.—This is a useful yellow sort blooming from June onwards, and averaging 1 yd. in height. Its variety *russelliana* is now considered synonymous with *P. viscosa* overleaf.

[1] *Phlomis fruticosa* is classed by Paxton and other authorities as a hardy evergreen shrub, but it nevertheless finds a place in the *Kew Handlist of Herbaceous Plants*. The same remark applies to *P. viscosa*.—EDITOR.

P. russelliana.—Syn. *P. viscosa* below.

P. samia.—This bears pure purple flowers in June, and averages 2½–3 ft. in height.

P. viscosa (Syns. *P. lunarifolia russelliana* and *P. russelliana*).—This bears yellow flowers from June onwards, and averages 2–4 ft. in height.

PHLOX (Nat. Ord. Polemoniaceæ). Half-hardy annuals (9 ins. high) and hardy perennials 2–4 ft. high.

The subulata section is trailing. They succeed in ordinary enriched garden soil, but *Phlox subulata* prefers a light medium with some peat.

Culture.—The annuals are propagated by seed sown in February or March in slight heat, or in April or May in the open. The perennials by seed sown in similar fashion; by cuttings of young shoots in spring; or by root division during the dormant season. The subulata or spring flowering Phlox can be increased by cuttings in summer, which will root best in sandy soil under glass.

Uses.—*Phlox decussata* is the perennial variety which has become so marked a feature of our herbaceous borders. It thrives best in a rich loamy soil in partial shade, but will do equally well in full sun if abundant moisture during summer is provided. For giving a brilliant display in the garden during July and August, few flowers can compare with this subject. Equally beautiful are the spring flowering species in April and May. These are seen to best advantage on the rockery and trailing over a low wall. The Annual Phloxes are effective in small beds, and in rockwork are wonderfully floriferous, and bloom over a long period.

Varieties.

Annual Section.—Selected strains of Drummondii and Hortensiæflora.

Decussata Section. — Elizabeth Campbell, Derviche, Fort de France, Frau A. Buchner, General Van Heutsz, Gipsy Queen (Gruppenkönigen), Hans Volmoller, Le Mahdi, Rijnstroom, Mrs H. F. Bowles, Selma, and Sergent Lovy.

Subulata Section. — Brightness, Daisy Hill, Fairy, G. F. Wilson, Little Dot, Nelsoni, Newry Seedling, The Bride, Vivid.

J. L. G.

PHLOX: Rock Garden Species. About half a dozen species are suitable for the rock garden. These thrive in open situations if a sandy loam is provided. They are propagated by division of the roots in autumn or spring, by cuttings in July, and by seeds sown in March and April.

Phlox amoena.—A dwarf spreading plant. Flowers are a rose colour. Site open. Soil sandy loam. Flowering Period, May. Height, 4 ins.

P. divaricata.—An erect tufted plant. Flowers lavender blue. Site, half-shade. Soil rich sandy. Flowering Period, May to June. Height, 1 ft. Its variety *alba* is white.

P. ovata.—An evergreen spreading species. Flowers rosy-pink. Site, half-shade. Soil rich loam. Flowering Period, May to August. Height, 1 ft.

P. reptans.—A creeping plant. Flowers are a rose colour. Site open. Soil sandy loam. Flowering Period, April to July. Height, 4 ins.

P. stellaria.—This bears tufts of wiry stems and narrow leaves. Flowers white and starlike. Site sunny. Soil rich sandy. Flowering Period, May to July. Height, 9 ins. There are numerous garden varieties of this, including *Bridesmaid, lilacina,* and *Seraph.*

P. subulata (Moss Pink).—This forms a mass of prostrate stems. Flowers rose-pink. Site sunny. Soil rich sandy. Flowering Period, April to July. Height, 3 ins. Numerous varieties of this are grown. See article above.

See also *Water Garden : Plants for the.*

PHOENICIAN JUNIPER (*Juniperus phoenicea*).—See *Trees.*

PHŒNIX.—For the best species see *Palms.*

PHŒNIX PALMS.—See under Phœnix in *Palms.*

PHORBIA.—See Cabbage Root Fly and Onion Fly or Maggot in *Insect Pests.*

PHORMIUM (Flax Lily, New Zealand Flax, etc. Nat. Ord. Liliaceæ).—Only a few of the somewhat numerous species and varieties of this are worth cultivating in general gardens. Botanically they are hardy herbaceous perennials succeeding in rich loam inclined to be clayey. They are not difficult to propagate by root division in the spring, which is also the best time for planting. We recommend the following :—

Phormium cookianum (Syns. *P. Colensoi* and *P. forsterianum*).—This bears yellow flowers from June to August, and grows 4–6 ft. high.

P. robustum.—This is a strong-growing sort similar otherwise to the above.

P. tenax.—Of the many varieties of this popular species probably the best is *variegatum,* the flowers of which are a somewhat unattractive whitish-green, and the foliage striped with gold. The plant blooms from August to September, and grows about 6 ft. high, and sometimes more.

PHOSPHATE OF AMMONIA.—See Ammonium Phosphate in *Ammonia and Ammonium Compounds.*

PHOSPHATE OF LIME.—See Calcium Orthophosphates in *Lime Compounds.*

PHOSPHATE OF POTASH.—See Potassium Phosphate in *Potash and Potassium Compounds.*

PHOSPHATE OF SODA.—See Sodium Phosphate in *Soda and Sodium Compounds.*

PHOSPHATIC MANURES and PHOSPHO-NITROGENOUS MANURES.—See *Manures.*

PHOSPHORIC ACID.—See under Phosphorus in *Chemistry for Gardeners,* also *Acids : Their Uses in Horticulture.*

PHOSPHORUS.—A few notes on this useful element will be found in *Chemistry for Gardeners.*

PHOTINIA.—For the best species see *Shrubs.*

PHOTOSYNTHESIS.—See under Food Synthesis and Transpiration in *Plant Physiology.*

PHRAGMITES (Reed. Nat. Ord. Gramineæ).—One species of this is sometimes offered to unwary amateurs. This, *P. communis,* is the common Spire Reed of the ditches, a plant to be given a wide berth.

PHUOPSIS (Nat. Ord. Rubiaceæ). One species of this is sometimes grown in the herbaceous border as it is a hardy perennial of very easy culture, and quickly propagated by root division in March. The species referred to, *P. stylosa* (Syn. *Cruciannella stylosa*), is a pretty pink summer blooming plant about 9–12 ins. high, its only disadvantage being the strong, rather unpleasant smell of its flowers.

PHYCOMYCETES.—A group of Fungi. See *Fungous Diseases.*

PHYGELIUS.—See *Cape Figwort.*

PHYLLOCACTUS.—A genus of cactaceous plants. See *Cacti.*

PHYLLOSTACHYS.—See *Bamboos.*

PHYLLOTRETA.—See Turnip Flea Beetle in *Insect Pests.*

PHYMATODES.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING.*

PHYSALIS (WINTER CHERRY. Nat. Ord. Solanaceæ).—This is a genus of herbaceous perennials which are hardy in the warmer parts of the British Isles. They do not require anything special in the way of culture beyond a rich soil and a sheltered site in the borders. Propagation by seeds, cuttings, and root division at the usual time is not a matter of much difficulty, while the best planting period is from early March onwards. We recommend the following, especially the first two; these bear attractive red seed capsules after blooming which are useful for winter decoration:—

Physalis Alkekengi (BLADDER HERB).—This bears white flowers from July to September, on plants about 1½ ft. high.

P. Bunyardii.—This is a handsome white-flowered hybrid of the above. It is more free flowering, and has larger seed pods.

P. edulis.—Syn. *P. peruviana* below.

P. Francheti.—This is a white species blooming from August onwards, and averaging 1½ ft. in height.

P. peruviana (Syn. *P. edulis*).—This is the well-known CAPE GOOSEBERRY, bearing yellow or white flowers from July onwards, and growing 3–4 ft. in height.

PHYSICS.—See *EDUCATION AND GARDENING.*

PHYSIOLOGICAL DISEASES.—These are referred to in our article on *FUNGOUS DISEASES.*

PHYSOSTEGIA.—See *FALSE DRAGON'S HEAD.*

PHYTEUMA.—See *HORNED RAMPION.*

PHYTOLACCA (POKEWEED. Nat. Ord. Phytolaccaceæ).—This is a small and not very important genus of hardy perennial plants (the half-hardy sorts being hardly ever grown). All the species described below will succeed in light rich soil in a sunny site if given the usual treatment for perennials, and are most easily propagated by seeds sown in the summer, or by root division in March, which last is also the best planting period.

Phytolacca acinosa (Syn. *P. esculenta*).—This, the INDIAN POKE, bears lilac-purple flowers and blooms in August. It grows about 4–5 ft. high.

P. bogotensis.—This is a tender white species blooming in June, and growing about 1 yd. high.

P. decandra (Syn. *P. vulgaris*).—This, the VIRGINIAN POKEWEED or POKEBURR, is quite the most favourite species of all. It bears white or pale purple and lilac flowers from June to August, followed by purple berries, and grows about 3–4 ft. high.

P. esculenta.—Syn. *P. acinosa*, which see.

P. icosandra (Syn. *P. purpurascens*).—This bears unattractive greenish-purple flowers in July, and where space is precious may be dispensed with. It may be planted in the wild garden or shrub border, where it will grow about 1 yd. in height.

P. octandra.—This bears greenish-white flowers in September and is only useful for a warm spot in the wild garden. It grows about 1 yd. in height.

P. purpurascens.—Syn. *P. icosandra* above.

P. vulgaris.—Syn. *P. decandra* above.

PHYTOMYZA.—See CABBAGE LEAF AND STALK MINER and MARGUERITE FLY in *INSECT PESTS.*

PICEA.—For the best of the numerous species see *TREES.*

PICHI (*Fabiana imbricata*).—See *SHRUBS.*

PICKLING CABBAGE.—See *RED CABBAGE, or PICKLING CABBAGE.*

PICKLING ONIONS.—See *ONION.*

PICKLING PLANTS.

The following is a list of the chief pickling plants, articles on the culture of which appear elsewhere in this work. It should be remarked that the term "pickling" is used in its widest sense, to include not only those plants pickled in vinegar, but also some pickled in sugar or salt, as, for instance, Angelica and Beans :—

Angelica.	Garlic.
Beans of many kinds.	Gherkin.
Beetroot.	Gourds.
Broccoli.	Leek.
Capsicum.	Nasturtium Seed.
Carrot.	Onion.
Cauliflower.	Radish.
Chili.	Samphire.
Chives.	Shallots.
Cucumber.	Tomato.
Cummin.	Unicorn Plant.
Egg Plant.	Vegetable Marrow.
	Walnut.

PICNOMON.—Now included in the genus *CNICUS.*

PICOTEE (Nat. Ord. Caryophyllaceæ).—Hardy perennial, 2½–3 ft. high, succeeding in compost of turfy loam two parts, leaf-soil and old manure half a part each, with some mortar rubble if grown in pots. For the open border, a well-drained substantial loam, enriched with manure, and containing lime in some form, is suitable. Burnt garden refuse is also recommended. New varieties are propagated by seeds. For perpetuating the named sorts layering is necessary.

Culture.—Sow seed in March or April in pots or boxes of light soil in a cold greenhouse or frame. Prick out before any crowding interferes with growth, and finally plant in a prepared bed in September or early October. Take layers as for Carnations. These will root in six or eight weeks. They may then be potted into 4-inch pots in good soil and, if to be grown under glass the following year, wintered in a frame or cold house. In February or March the pots will be well filled with roots. Then transfer the plants to their flowering quarters, one plant in a 6-inch pot or two in a 7½-inch pot.

Although strictly a hardy plant, the white-ground Picotee has, through generations of culture under glass, lost the robustness of its original constitution, and is now solely grown in the cold greenhouse. Frost will not injure it, but the dampness of our winters is too trying to this aristocrat of the floral world. The yellow-ground Picotees are more amenable to border culture, but this is probably entirely owing to their more recent evolution. The flowering season is July and August.

Varieties : — *Yellow Ground.* — Eclipse, Exquisite, Her Majesty, John Ruskin, Margaret Lennox, Mrs J. J. Keen, Onward, Santa Claus, Togo.

White Ground. — Fair Maiden, Henry Kenyon, John Smith, Lavinia, Liddington's Favourite, Mary D. Anstiss, Perfection, Polly Brazil, Radiant.—J. L. G.

PIERIDÆ. — See CABBAGE WHITE BUTTERFLIES in *INSECT PESTS.*

PIERIS.—For the best species see *SHRUBS.*

PIG MANURE.

Pig dung is one of the most smelly materials a gardener ever has to handle, and for this reason alone cannot be used in a fresh state in the vicinity of dwelling-houses. Nor is it easy to use it on suburban allotments without running serious risk of a visit from the Inspector of Nuisances and a consequent summons.

Where, however, facilities exist for making use of it (and this is

usually possible in the neighbourhood of country farms) the opportunity should be seized, for though pig manure is so offensive, it is good stuff, and wonderful crops have been produced by its use on light and medium soils. Let it, however, be clearly understood that fresh pig dung is quite useless for all gardening purposes, and that however old it may be it should not be used on strong heavy clay soils.

Pig-sty Refuse. — The common practice now, and the almost universal practice ten or twenty years ago was to allow one's pigs to wallow in all the dirt of the day. The sties are usually large and, instead of being kept as clean as the proverbial new pin, they were, and, alas, still are in many cases, the incarnation of all that is filthy. Manure from the stables, cow-dung from the byre, and the sweepings of the farmyard are frequently shot into the pig-sty for the pigs to wallow amongst. Household refuse of a varied nature is usually thrown in too for the pigs to eat. The resulting manure is a mixture of indefinite composition and may be used in the same way as *FARMYARD MANURE*, upon which we devote a separate article.

Pure Pig Manure. — The more progressive pig-keepers are now departing from the above practice, and do not allow their pigs to wallow amongst every kind of filth in the way indicated. Clean straw is provided for them to lie on, and the dung is removed daily with the soiled straw. This is the powerful material so useless in its fresh state, but which gardeners working light soils should purchase in as large a quantity as possible. It is, as every one who has handled it knows, a watery solid the odour of which is very penetrating.

The best way to turn this material into valuable manure is a matter of opinion. Some advocate mixing large quantities of lime with it, but if this is done much of its value is lost. The best way seems to be to mix it with nearly as much as its own bulk of poor garden soil, or vegetable refuse, the latter for preference. A conical stack of the mixture should then be made in an out-of-the-way spot, and after being beaten firm this should be covered with a 6-inch layer of soil to which ground gypsum has been freely added. The heap should be allowed to mellow down for about a year ; it can then be dug out, and this covering soil mixed in, after which it will form a fine material for winter manuring, if used at the rate of 3–5 cwt. per sq. rod.

It is needless to add that the gardener should only work amongst pig manure on a full stomach, and that if hard materials, such as dried bracken or green fern, are used for bedding the pigs in the absence of straw, a somewhat longer period should be allowed for the material to rot before it is used.—E.

PIG-NUT (*Carya porcina*). — See *TREES*.

PIG NUT (*Carum Bulbocastanum*).— See *CARUM*.

PIG-STY REFUSE.—See *PIG MANURE*.

PIGEON DUNG. — See *POULTRY MANURE*.

PILEWORT (*Ranunculus Ficaria*).— See *RANUNCULUS*.

PILLAR FORGET-ME-NOT (*Myosotis stricta* and *M. Sutton's Gem*).—See *FORGET-ME-NOT*.

PILLAR ROSES.— See under ROSES FOR PILLARS in *ROSES FOR ALL PURPOSES*.

PILOCEREUS. — A genus of cactaceous plants. See *CACTI*.

PIMPERNEL.—See article on *ANAGALLIS*, and under SCARLET PIMPERNEL in *WEEDS*.

PIMPERNEL, THE BOG (*Anagallis tenella*).—See *ANAGALLIS*.

PIMPINELLA.—See under ANISEED in *MEDICINAL HERBS.*

PIN OAK (*Quercus palustris*).—See *TREES.*

PINE.—For the best sorts see PINUS in *TREES.*

PINE BEETLE.—See *INSECT PESTS.*

PINE NEEDLES.

These are of no value to the gardener except for starting his wood fire. They prove detrimental when dug into the ground and ruin the resulting leaf-mould if mixed and allowed to rot with leaves.

PINE WEEVIL.—See *INSECT PESTS.*

PINGUICULA (BUTTER-WORT. Nat. Ord. Lentibulariaceæ).—This is a genus of hardy alpine aquatics of little garden value. *P. alpina* (Syn. *P. flavescens*) and *P. grandiflora,* bearing white and blue flowers respectively, are sometimes grown in the water garden. The best known species is, however, *P. vulgaris* (Syn. *P. Gypsophila*), popularly known as the BOG VIOLET, bearing small purple-violet flowers in April and May. The height of all the above species averages 3–6 ins.

NEW VARIETY.

Pinguicula Renteriana.—This has rose flowers mottled with purple in the throat. It thrives best in moist soil in the rock garden.

PINK (Nat. Ord. Caryophyllaceæ). A hardy perennial, 9–12 ins. high, succeeding in ordinary garden loam, preferably containing lime or mortar rubble, and propagated by seed, layers, cuttings, or pipings.

Culture.—Seed sown in boxes or in the open border in April and May will produce strong bushy plants by September, when these should be planted firmly in their flowering quarters. Layering is not frequently resorted to, as pipings and cuttings root very readily and take much less time to prepare. After the flowering season the current year's "grass" will be in good condition for treating in this manner. Pipings are secured by severing, with a sharp upward pull, the top portion of the young growths about 3 or 4 ins. long, and inserting them in sandy soil in a shady position, the lowest pair of leaves being removed to form a short stem. Some of the side-growths will be found sufficiently short to be taken with a "heel" from the old stems and used as cuttings. If the weather is hot and dry, overhead syringing will facilitate rooting. In about six weeks the young plants can be moved to their permanent quarters.

USES.—The Pink is an excellent subject for bordering or edging, the evergreen glaucous foliage having a pleasing effect even when the plants are not in bloom; but more use might be made of them planted in clumps in the rockery.

Varieties.—Many new sorts have been introduced lately which are a distinct advance on the older varieties, such as Mrs Sinkins. The following are particularly fine: Apple Blossom, Aviator, Bookham Gem, Border Chief, Charm, Dido, Emperor, General Joffre, Glory, J. L. Gibson, Jasper, King Pink, Progress, Radiant, Snowdrift, The Gem, Vesta, White Queen.—J. L. G.

PIOPHILA.—See CELERY STEM FLY in *INSECT PESTS.*

PISTACHIO NUT.—See *NUT CULTURE.*

PISUM (PEA. Nat. Ord. Leguminosæ).—The most important species in this genus is *P. sativum*, the COMMON PEA, CULINARY PEA, or GARDEN PEA (see article on *PEAS*). Others, such as *P. arvense*, the FIELD PEA, and *P. elatius* (Syns. *P. biflorum* and *P. thebaicum*), the MUMMY PEA, are grown in the garden to a much more limited extent. Some authorities give *P. arvense* as a synonym of *P. elatius;* in other words, they call the FIELD PEA and the MUMMY PEA by the same name, which is absurd, as the two are such different plants.

PITCH PINE (*Pinus rigida*).—See *TREES*.

PITCH PINE, TRUE (*Pinus palustris*). See *TREES*.

PLANS.—See *GARDEN PLANS*.

PLANT PHYSIOLOGY.

If we pull or dig up a plant and, after washing its roots free from adhering soil, weigh it, then dry it thoroughly in a warm place, and weigh it again, we find that water has formed a very large proportion (often well over 90 per cent.) of the substance of the fresh plant. If we chop up the dried plant and heat the pieces strongly in a crucible or hard glass tube, they become first blackened (charcoal), and finally only a greyish powder (ash) remains. By collecting the gases given off during the burning (oxides of carbon, of hydrogen, and of nitrogen), we prove that the largest component of the dried plant consisted of carbon. The ash consists of oxides and salts containing the elements calcium, chlorine, iron, magnesium, phosphorus, potassium, sodium, etc. —in fact, ash analyses have revealed the presence in plants of every element found in the earth's crust, mostly in mere traces. To find out which of these elements are essential for the nourishment and growth of plants, we grow plants with their roots dipping into a *Culture Solution*, namely, water, to which is added various salts; and we find that all ordinary green plants thrive and grow, just as if they were rooted in the soil, if the solution contains the nine elements calcium, hydrogen, iron, magnesium, nitrogen, oxygen, phosphorus, potassium, and sulphur. We could have predicted that hydrogen, nitrogen, oxygen, phosphorus, and sulphur are essential, for these five elements, together with carbon, make up the actual living substance (*protoplasm*) of both plants and animals. Now, the usual culture solution contains no carbon or carbon compound, nor does a plant make use of one if it is added. Hence we know that the all-important element carbon comes from the air, as carbon dioxide ("carbonic acid gas"), a fact very easily proved by simple experiments.

Tissues. — Some of these points will be considered later, but we must now concentrate attention on the processes by which plants manufacture their food. The microscopic structure of plants cannot be dealt with here in detail, but the tissues are divided into three chief parts. (1) CONDUCTING TISSUES, including the woody parts of the root and stem and the leaf veins. Besides the wood vessels up which water passes, special tubes (*sieve-tubes*) for carrying certain foodstuffs from the leaves to other parts of the plant are also included in these tissues. (2) GROUND TISSUES, more or less spongy in texture, since these include air-spaces. In root and stem these serve mainly for food storage, but in the leaf the ground tissues are green, and are the seat of the most important process in plant life. (3) PROTECTIVE TISSUES, which serve mainly

to prevent escape of water, but which in the root bear countless fine hairs which absorb water and salts from the soil, while in the leaf these tissues are perforated by small openings (*stomata*) through which important exchanges of gases take place between the outer air and the air-spaces within the plant.

Food Synthesis.—By a remarkable series of processes, green plants, alone of all living things, build up organic compounds from the carbon dioxide of the air and a few elements absorbed from the soil. The first step (*Carbon Assimilation*) is the splitting up of carbon dioxide and water, and the rearranging of the elements carbon, hydrogen, and oxygen so as to produce simple organic compounds. There are intermediate products, but finally sugars are formed. Some of the sugar is at once used up to supply energy to the green tissue itself, some passes along the conducting tissue to parts of the plant which are growing or are storing food, while some is temporarily changed into the allied, but insoluble substance starch, for storage in the green leaf tissue itself. Starting from sugar, various other organic compounds are built up containing (besides carbon, hydrogen, and oxygen) the elements nitrogen, phosphorus, and sulphur, and finally the living substance protoplasm itself is produced. Of these two sets of synthetic processes—carbonic acid to sugar, sugar to protoplasm—the first (*Carbon Assimilation*) depends absolutely upon light, and occurs only in the green leaf, while the second is independent of light, and may be carried on in any part of the plant. We may call the first *photosynthesis*, and the second *proteid-synthesis*.

A little reflection shows the unique and fundamental importance of these synthetic processes, which green plants alone can carry on, and upon which all other living things are directly or indirectly dependent for their food, and therefore for their life. We know very little about the later stages, but as regards *photosynthesis*, we know that the green matter (*chlorophyll*) of leaves absorbs the red and blue rays of the mixed (white) light falling on it, and that the absorbed rays somehow supply the living protoplasm with the energy required to carry out the synthesis of sugar from carbonic acid (*i.e.* carbon dioxide from the air, dissolved in water derived from the soil). The vast importance of having the plant's leaves well exposed to the light and air is thus obvious.

Essential Elements.—The reason why six out of the ten "essential elements" *are* essential is clear enough from the fact that they are constituents of protoplasm itself. But why are the other four also essential? As to iron and magnesium the reason is clear—without these elements the green matter (*chlorophyll*) cannot be formed; magnesium actually enters into the composition of chlorophyll, but as iron does not, the precise part played by iron is not clear. Potassium is an ingredient in certain organic compounds, found especially in some crucifers (*e.g.* "oil of mustard"), but apparently its chief functions are somehow connected with carbon assimilation and with the transport of organic foodstuffs in the plant. Calcium compounds (lime salts) are also concerned in some way in photosynthesis and proteid-synthesis, besides combining with, and converting into a harmless insoluble salt, a poisonous by-product (*oxalic acid*) formed in these synthetic processes, while its compounds also enter into the composition of, and give additional strength to, the supporting (cell-wall) framework of plant tissue.

Besides the ten elements which are essential and sufficient for healthy growth of all green plants (so far as known from water culture experiments), a few others occur in considerable amount in certain plants. In some cases these additional elements certainly make for more robust growth; for instance, grasses and cereals store up silica (from quartz, flint, or sand) to stiffen their stems and leaves, while common salt (*sodium chloride*) seems to promote the growth of plants of the goosefoot family (spinach, beetroot, etc.), as well as some of the few edible umbelliferæ, notably the carrot.

Respiration.—Plants, like animals, use organic foodstuffs as material for tissue formation in their growth, and as "fuel," which is slowly burned or oxidised, in order to supply energy for the various functions of life. Actual locomotion, characteristic of animals (often only in early life, as in oysters and other sedentary animals), is, in the vegetable kingdom, seen only in lowly microscopic plants, and in certain reproductive cells of higher ones; but more or less active streaming movements of protoplasm can be seen with the miscroscope in all

plants—for instance, in the green cells of leaves, the protoplasm moves so as to place the disc-like chlorophyll grains broadwise in moderate light, but edgewise in too intense light which injures the chlorophyll. Also, energy is expended in the chemical transformation undergone by the organic foodstuffs in plants, just as in animals; these foods are oxidised, with the setting free of heat and of carbon dioxide, besides other waste products which are stored inside the plant, instead of being excreted as in animals and man. In plants, as in animals, part of the energy produced by oxidation (*respiration*) is set free as heat, but in plants this occurs slowly, and the heat is soon dissipated so that the tissues take the temperature of the air around; though in germinating seeds and opening buds and flowers, respiration may be as active as in warm-blooded animals, and the temperature rise by several degrees. The oft-repeated steam-engine analogy applies to plants just as to animals or our own bodies; and a free supply of air containing the necessary oxygen for respiration is as important for plant life as for that of animals. For instance, the functions of the root, and therefore those of the rest of the plant, suffer (1) if the soil is waterlogged (*i.e.* if the air between the soil grains is replaced by water, as may happen naturally in heavy clayey soil during prolonged wet weather, or in any soil if it is over-watered); and (2) if seeds are planted too deeply in the soil, since the lower parts of most soils contain much more water and far less air than the upper part. A well-ventilated soil then is a most important condition for the healthy growth of plants. The ground tissue of roots contains air-spaces continuous with those in stem and leaves, and this internal ventilation system is specially well developed in marsh and aquatic plants, but ordinary land plants must also have a well-ventilated soil to grow healthily in.

Transpiration.—A leaf plucked from a living plant, or a pulled-up seedling, after a time becomes limp, then dry and withered, and finally dies owing to loss of water in the form of vapour. This loss occurs chiefly from the leaves through the pores (*stomata*), which, as a rule, are most numerous on, or confined to, the underside of the leaf. Through these pores there is communication between the air-spaces, or ventilation system, inside the plant and the atmosphere outside. Through them also occur the exchanges of gases between plant and atmosphere connected with photosynthesis, respiration, and transpiration. Experiments made on the diffusion of gases through perforated metal discs, also on these three processes in plant life, show how marvellously the green leaf is adapted to its great functions. As to the stomata, at first sight the presence of small pores dotted over the skin-layer would seem a very inadequate means for the entry and exit of gases, but, as a matter of fact (omitting its physical and mathematical explanations), the pores when open are in effect equivalent to a perfectly free surface—that is, as rapid gaseous diffusion occurs as if no skin were present at all! But the pores are not always open, and when they are closed the skin forms a protection against loss of water which might damage or kill the leaf. The two guard-cells which surround each pore are sausage-shaped, and are capable of becoming less curved (which state is termed *pore closing*) or more curved (when the pores are said to be open) according to conditions. Thus the pores open on bright, dry, warm days, and close when it is dull or dark, or when the air is moist or cold.

The leaves have often been likened to the lungs of the animal body, and this is largely correct, for we must remember that the actual surface where exchange of gases between the plant and the atmosphere occurs is not the outer surface of the leaf, but the enormous area presented by the walls of the cells inside the leaf, that is, the walls of the continuous, though labyrinthine air-space system of the plant. The leaf-pores serve simply as the outer doors of entry and exit for the gases concerned—enter carbon dioxide and exit oxygen in photosynthesis; the reverse in respiration—exit water vapour in transpiration. Just as the green chlorophyll-containing leaf-cell is the all-important unit in nutrition (*photosynthesis*), the factory to which are brought the raw materials (carbon dioxide from air, water and salts from soil) which, by aid of the light-energy absorbed by the green grains, are transformed into sugar and other complex organic foodstuffs, so in transpiration the green cell again is the active agent in

not only giving out, as vapour, the excess of water drawn up from the soil, but also in the actual drawing-up process itself. We shall study presently the absorption of soil-water, but once water has entered the conducting pipes (wood-vessels) the maintenance of the ascending water stream through stem to leaf is due to the powerful sucking action of the leaf-cells, exerted in the process of osmosis (see below). That is, the transpiration stream is due, not (as still often erroneously taught) to a driving force exerted by the root from below, but to the pulling force of the transpiring leaf-cells from above.

Root Absorption.—This is closely related to nutrition and transpiration. The essential function of the root, besides that of fixing the plant firmly in the soil, is to absorb soil-water, which is a weak solution of various salts. The root may also fulfil other functions, one of the commonest of these being the storage of food (*e.g.* beetroot, potato). The area presented by the root to the soil is increased not only by its copious branching, but by the production of long, fine outgrowths (or root-hairs) which increase its apparent area a hundredfold or more. These hairs, which are long, tubular outgrowths from the skin layer of the root, have an outer wall, lined inside by a film of living protoplasm, while within this again is the cell-sap—a solution of numerous substances, organic and inorganic. Root hairs are best seen in seedlings grown on moist flannel or paper, or simply in damp air; they can rarely be seen if we dig or pull up the root from the soil.

Next to the green leaf-cells, the root-hairs play the most important active part in the nutrition of plants. The root branches in all directions, so as to explore as much soil space as possible by means of the hairs, which are borne just behind the growing tip of each rootlet. The branching root also fixes the plant securely in the soil, so that the wind shall not disturb or break off the finer rootlets and the hairs; the stem and its branches spread the leaves (which are practically layers of green cells) out in the air and light, so as to obtain as much of both as possible, while preventing one leaf from unduly shading the others; and throughout the branching root and stem are the conducting tubes between the root-hairs below and the green cells above. The reader who grasps this broad conception of plant structure can, of course, fill in the many interesting details from further study, but will have nothing to unlearn.

Osmosis.—As to the actual mechanism of root absorption, we can here again give only a general outline; for fuller knowledge reference must be made to books on chemistry, some knowledge of which is essential for the better understanding of plant physiology. It is well known, however, that when two solutions of different strengths are separated from each other by a membrane such as parchment or pig's bladder, the weaker (less concentrated) solution passes through more rapidly than the stronger; hence if we fill a bladder or a parchment tube with salt or sugar solution, and suspend it in water, it will soon swell up very much. That the stretched membrane is under considerable pressure is obvious, for if we prick it the liquid spurts out. After a time (unless the membrane bursts) it will stop swelling and subside to its original size, because from the start the diffusion process has been going on in *both* directions. In other words, water has been passing into the bladder, and solution has been passing out into the water, so that finally we have solutions of equal strength inside and outside it. Roughly, this illustrates the process of *osmosis* which occurs in root absorption; within the root-hair is a solution of salts, sugar, etc., and outside it the soil-water (a weak solution of salts). But the root-hair, besides its dead outer membrane or cell-wall, has an inner layer of living protoplasm, and when the cell-sap reaches a certain concentration, some change occurs in this living layer whereby it regulates the rate at which soil-water is absorbed, and also, at the place where it joins the root tissue, causing part of the cell-sap to escape under pressure into the vessels. Owing to the action of the living layer, the root-hair, unlike a dead membrane, does not swell up and burst, but continuously absorbs soil-water, and passes it on under pressure into the vessels, where it begins its ascent into stem and leaves. This "root pressure" is, in certain circumstances, sufficient to force water right up to the leaves. For instance, at night when the air-pores of the leaves are closed, water may be forced out in drops from special ever-open pores on the edges of the leaf,

just where the veins end, as in nasturtium (*Tropaeolum*) or fuchsia; again, in spring, before the leaves have unfolded, sap escapes when twigs of maple, vine, etc., are cut. But this escape of liquid is not transpiration; as a matter of fact, when transpiration is active, as on bright, warm days, the column of water in the wood vessels is broken up by bubbles of water vapour. Paradoxical as it may appear, this column of water (even when so broken up), extending from roots to leaves, behaves like a solid rod—it is drawn up, without any break in its continuity, by the sucking action of the transpiring green cells. Here, again, osmosis comes into action—the wet walls of these cells lose water to the air inside the leaf, hence their cell-sap becomes more concentrated, and they draw water from the vessels in the leaf-veins, which are continuous with those in the stem and root.

"Selective Absorption."—Keeping these principles in mind, we can arrive at clear ideas concerning so-called selective root absorption, a most important process, which is simple enough in reality, but which has often been the subject of confused and erroneous explanations. Root-hairs must, of course, absorb any diffusible substance present around them; for instance, if the root of a plant is set into a poisonous solution, it absorbs this, and as the solution is drawn up it kills the plant. The root is, so to speak, obliged to go on absorbing any diffusible substance present in the soil-water, so long as that substance is used up to form part of the plant's own substance. But if the substance is one of which the plant makes no use, and does not change into some insoluble compound, then it accumulates in the cell-sap, and when the concentration here equals that outside, the absorption of the substance stops. This applies alike to useful and to useless substances. It explains the fact that all plants contain, often as mere traces, various chemical elements besides the nine essential ones absorbed by the root. Since one species differs from another in the relative requirements of even the essential elements, it follows that if the same species is grown in the same mass of soil year after year, the plants may after a time fail to obtain enough of one (or more) of these elements, and will show poorer growth, though the soil may still be rich enough in this element to support the luxuriant growth of a second species, which in turn may impoverish the soil in respect of some other element, and so on. On these facts is based the correct use of manures and artificial fertilisers, as also the rotation of crops, and reference to our articles on these topics will give fuller information.

Besides absorbing water and salts from the soil, roots excrete certain substances *into* the soil-water. Of these the most important is carbon dioxide (produced by respiration, also by the decay of dead root-hairs), and this gas, when dissolved in water, forms a weak acid (*carbonic acid*) which dissolves such substances as carbonates and phosphates of lime and magnesia. Roots also appear to excrete substances which are injurious, at any rate in water cultures, to the growth of other plants of the same species, and this may be an additional factor governing the rotation of crops.

Relations of Plant to Soil.—So far, we have considered the relations between root and soil mainly from the chemical point of view, and have barely touched upon the physical conditions which must also be fulfilled for plants to grow healthily in a soil. The root gets all the organic foodstuffs for its growth from the leaves, through the stem, since (having no chlorophyll) it can manufacture none for itself; like the other non-green parts of the plant, it is, so to speak, parasitic on the green leaf, the food-making factory. But its growth requires suitable conditions as to water and air supply, warmth, soil texture, etc.; and besides these various physical factors, which in their influence on plant growth may co-operate or clash with each other in a most complex manner, we have biological factors, such as the presence and activities of insect larvæ, earthworms, fungi, protozoa, and bacteria, of which some are beneficent and others injurious in their influence on soil fertility.

The reader will, of course, understand that a general discussion of soil questions cannot be given here. Details as to the use of manures and fertilisers, and as to cultivation generally, as well as the special cultural requirements of different species, will be found throughout this work.

Food Storage and Digestion.—As already explained and emphasised, the green plant has the unique and

fundamental power, by virtue of its chlorophyll apparatus, of converting the simple inorganic raw materials, carbon dioxide and water, into sugar, which in turn forms the starting-point for further synthetic processes in which nitrogen, sulphur, and phosphorus are worked up into more complex foodstuffs (amino-acids and proteins) which are finally incorporated into the actual living substance called protoplasm. It is true that in the all-important early steps of this synthetic series the green plant is sharply distinguished from all other living things, which therefore depend upon it for their existence. In the animal body, we must begin with already complex foodstuffs, and those containing nitrogen, sulphur, and phosphorus are essential for life. The important point to be noted now is that the actual organic foodstuffs themselves are precisely the same in plants and animals, namely, carbohydrates (sugar, starch, etc.), fats, and proteins; and further, the *fate* of these substances is the same in both cases, that is, they are either used as material for growth, or oxidised in order to provide energy (already discussed under the heading RESPIRATION), or stored for a longer or shorter time before being used in one or other of these two ways.

When stored, generally in insoluble and indiffusible form (*i.e.* incapable of passing through membranes), these foodstuffs must be converted into a soluble and diffusible form which can pass from cell to cell, by the process of diffusion (osmosis), to the parts which require food for immediate or future growth. This conversion is effected, just as in the animal body, by the action of the remarkable substances called ferments (*enzymes*). Most of these ferments are so strictly specialised that each acts upon only one kind of foodstuff. Without discussing the matter more fully, we may say the action has been compared with that of a lock and a key, and that as there are numerous combinations of locks (the more complex and less soluble or less diffusible foods) there is a correspondingly large number of keys (ferments or enzymes) to fit them and to open the door, or in other words, to convert the locked-up substances into simpler, more soluble and diffusible ones. Ferment action is very different from that of a mere solvent or dissolving substance; for if we add hydrochloric acid to lime, for example, we get a new salt (chloride) of lime, which is soluble, but the acid is used up in the change; whereas one peculiarity of ferments is that an infinitesimally small quantity can go on continuously converting, say, starch into sugar, without itself undergoing any final change or loss so long as the sugar is removed from the field of action.

The green leaf manufactures food so long as the light shines on it, and other conditions are favourable; at nightfall it contains a surplus of food in the form of minute starch granules, embedded in the green chlorophyll grains; the ferment diastase changes this starch back into sugar, which travels in solution to parts which are growing (roots, buds, young leaves, flowers, etc.), or which are laying up a reserve store of food for future growth (seeds, rhizomes, tubers, bulbs, etc.); in these storehouses the sugar is changed back once more into starch, which is deposited in granules in or around grains (*leucoplasts*) resembling the chloroplasts, but containing no green substance. So the cycle goes on; so long as life and growth proceed, dissolved food is used up or stored up, and thus a stream of diffusion sets in from the food-making or food-storing parts of the plant to the parts where active processes are carried on, and where food is used up. The storage is merely temporary, though it may last from autumn to spring (bulbs, rhizomes, etc.) or for some years (seeds); when the time of need comes, ferments convert the stored food into diffusible food, and this streams to the places where it is required.

Growth.—Growth in plants, as in animals, involves not merely increase in size, but the building up of additional living substance (*protoplasm*) at a greater rate than it is broken down; that is, growth normally implies an excess of construction over destruction, so that material and energy are stored up faster than they are lost. It is obvious that growth may proceed actively in some parts of the plant at the expense of others, so that for a time the plant may show great increase in size but a loss in dry weight, as, for instance, in germinating seeds or sprouting tubers, etc.; but as soon as the young leaves unfold, become green, and receive the light, progressive growth, with increase of

organic substance, begins, and continues during the growing season. Apart from intake of water, which is essential for all vital processes, and a supply of foodstuffs, growth requires oxygen and a suitable temperature. Growth takes place in all parts of the plant where there is living substance, but is especially active in the layer (*cambium*) which produces new conducting tissue in stem and root; in the cork-forming layer of old stems and roots; at the ends of roots and stems; and in the young leaves.

From what has been said here and in preceding paragraphs, it is obvious that normal healthy growth depends on the proper functioning of the green leaf-cells and the root-hairs. The leaves must have light and air in order to manufacture food; the root-hairs must be so placed as to explore the soil-spaces for water and salts. Hence the leaf-bearing shoots should not be closely crowded together so that the leaves unduly overlap and shade each other; while the soil should, besides containing the necessary salts and water, be of such texture that the growing root-tips (bearing the absorbing root-hairs) can reach out in all directions and come into intimate contact with the soil-grains. All the operations of culture —pricking-out, pruning, thinning, weeding, pest-destroying, watering, manuring, tillage, etc. — are directed towards promoting and, as far as possible, guiding in the right directions, the work of the green leaf-cells and the root-hairs, whether the outcome of growth be desired for pleasure or profit or both.

Movement.—Apart from internal protoplasmic streaming, plants show movements of various kinds, but we need consider here only those due to growth. These growth movements are also called "tropic" or "turning" movements, because unless and until the organ concerned has taken up its proper direction of growth, and reached the best position for the work it has to do, it does this by curvature due to growth taking place more rapidly, or solely, on one side of the growing root, stem, or leaf. The growing organs are exposed to the stimuli of light, gravity, moisture, chemical substances, contact with solid objects, etc. They frequently respond to these stimuli by growing towards the source of stimulation. At times, however, they grow away from it, or adopt a "neutral" attitude, *i.e.* growing at right angles to the line of stimulation.

Everyone has observed examples of such movements, *e.g.* the bending out of stems towards light falling from one side; the turning upwards of the growing tips of shoots that had been beaten down by rain or wind, etc. Unless one has performed or seen some simple experiments, however, it is difficult to realise what an important part growth movements play in plant life, or even that they take place at all, much less that they occur with great force, *i.e.* that the part concerned can overcome very considerable resistance in carrying out its movement.

The main stem responds to the stimulus of light by growing erect if in the open, but at an angle if the light comes mainly from one side; the leaves set themselves at right angles to the light, while branches move into a definite position intermediate between vertical and horizontal; thus the leaves are spread out so as to catch the maximum of the available light. The main root grows away from the light and towards moisture. It also grows vertically downwards, not in a merely passive manner, but with considerable force, towards the earth's centre, *i.e.* it is guided by the stimulus of gravity.

The first set of side-roots grow out in a direction below the horizontal; while the further branches from these simply grow at right angles to their parent, so that some grow upwards. In this way the root systematically explores the soil, its branches coming into contact with the largest possible soil volume with the minimum expense of material, *i.e.* unnecessary overlapping of rootlets is avoided. In brief, so far as the stimuli of gravity, light, and moisture are concerned, the main stem and main root grow in opposite directions (towards and away from the stimulus) along the line of stimulation, while branches and leaves and the main rootlets take up a more or less horizontal position. Moreover, in each case there are remarkable "perception organs," which receive the light and gravity stimuli and transmit them to the growing cells which carry out the movements.

Life History of Flowering Plants.—The necessarily brief and general outline of plant life here given may be concluded by a few remarks on reproduction by seed. The plant begins

life as an egg, a small cell embedded in the ovule or future seed, which is contained in the future seed-vessel (*ovary*) of the flower. The flower also produces, in the pollen sacs of its stamens, minute pollen grains which are ultimately transferred, either by insects, the wind, or human agency, to the receptive portion (*stigma*) of the ovary. The rest of the flower serves for protection of these essential parts, and for the attraction to them of insects which transfer pollen to stigma, and we find many wonderful adaptations whereby cross-pollination —which means eventually the blending of protoplasm from two distinct parents in the production of seed—is promoted. Placed on the stigma, the pollen grain sends out a fine tube which carries protoplasm from the male parent into the ovule and finally to the egg, where the two protoplasms blend; the tube is guided on its journey by chemical substances produced by the ovule, *i.e.* it shows growth movement in response to chemical stimulus. The fertilised egg grows and becomes the embryo or young plant; the ovule containing it becomes the seed; and the ovary becomes the seed-vessel. Inside the seed, either in the first leaves (*cotyledons*) of the embryo itself, or in a special tissue (*endosperm*) within the seed-coat, but outside of the embryo, there is stored up, as the seed ripens, a reserve of food (starch, proteins, oils, etc.); then the seed becomes firm and dry by loss of moisture and, protected in its coat, is able to endure extremes of heat or cold, and to remain dormant until its germination is evoked by the right conditions as to warmth, water, and air. These stimulate the root and shoot of the embryo into resuming their growth, which is carried on at first at the expense of the stored food, but ere long the seedling shoot has green leaves up in the air and light, and can then make food for itself.

Besides serving as a means for blending the characters of the parents, seed formation is on the whole the best method of perpetuation, since the mature dry seed is remarkably resistant to adverse external conditions; also, of course, the seeds are dispersed by such agencies as wind or animals, often to a considerable distance, so that the offspring are not crowded together. Other organs of perpetuation (tubers, bulbs, etc.) resemble seeds in that they contain reserve food for the growth of buds and roots, which give rise to new plants after the resting period has passed, and conditions have again become favourable for active growth. In all these cases, as in seeds, the stored food was originally manufactured by green leaves.

Throughout its life cycle, the plant is exposed to the various and varying conditions which make up its environment, and it responds to changes in the environment—in the light falling on it, the air around its leaves, the soil in which it is rooted—by modifying its behaviour in such a way as to adapt itself to these changes, and thus to succeed in the struggle for life. In a wider sense, the environment exerts a passive selective action on the race as a whole; when we speak of "natural selection" in connection with the origin of varieties or species, all we mean is that variations from the average or normal are subjected to the sifting action of the environment, which determines whether or not they shall survive and perpetuate the new forms which have arisen, either by small differences among the offspring of the same parents, or by more marked and sudden steps (mutations, sports). Further details will be found in the article on *Hybridising and Cross-Breeding*.—F. C.

PLANTAGO (Plantain. Nat. Ord. Plantagineæ).—This is a large genus of hardy herbaceous plants of no value whatever for gardens. Most of them are excessively troublesome weeds, and of these we may mention the Hartshorn Plantain (*P. Coronopus*); the Rib Grass (*P. lanceolata*); the Greater Plantain or White Man's Footprint (*P. major*); and the Lesser Plantain (*P. media*). See article on *Weeds* for means of control.

PLANTAIN. — See under Greater Plantain, Hoary Plantain, and Ribwort Plantain in *Weeds*. See also *Plantago*.

PLANTAIN LILY.—See *Funkia*.

PLANTATION LILY.—See *Funkia*.

PLANTATIONS OF TREES: Their Purpose.—What is the purpose of a plantation of trees? This

is a question which it seems landscape gardeners and those who have to lay out estates have neglected, since plantations are noticeable throughout the country which have been placed with practically no regard to their purpose. This seems a pity, for plantations, though lovely enough in themselves, may, if carelessly planted, mar instead of beautify a garden or estate.

One of the purposes of a plantation of trees is to block out ugly adjacent buildings or to conceal the view of houses, mines, quarries, railways, tram tracks, works, and so on, in the distance. The present writer knows of several gardens within five minutes' walk of towns, and surrounded by villas on all sides, yet one could not but imagine once in them that it was the heart of the country. This is all done by the skilful use of plantations of trees.

Yet another use of plantations is to form a suitable background for herbaceous colour borders. Here the taller shrubs mentioned in our article on *Shrubs* might serve this same purpose, though where the view is extensive trees would be necessary.

Probably the most important purpose of plantations of trees is that of wind screens, since in exposed districts, unless something of the kind is arranged, the more delicate plants cannot live at all.

Care should be taken that plantations of trees do not block out the sun from the garden, since sunshine is an absolute essential. Plantations which commence to do this have defeated their object, and should be promptly cut back to let light in.

One of the quickest growing trees is the sycamore. It is thus useful where a plantation is needed urgently.—E.

PLANTING.

This, next to sowing, is probably the most important of the gardener's operations, for on it depends the success or failure of his subjects to a considerable extent. It is proposed to give a few brief practical hints on the subject in this article.

Before attempting to do any planting, the soil should be well prepared and, very preferably, deeply trenched, keeping the bad sour subsoil in its place down below, but nevertheless breaking it well.

Planting, since it varies so much, is dealt with under separate headings.

Annuals and Bedding Plants.—These should be planted with a trowel in straight or curved rows, clumps or circles. Where clumps are used they should be proportionate to one another, for nothing looks worse than a gigantic clump of one plant here and a tiny patch of something else close by. When there is a view of the border from the house, it should be planted as is shown by the dots (representing plants) in Fig. 1, and not in the manner pictured at Fig. 2. If this last way is adopted, the soil between the rows is seen even

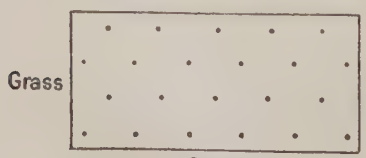

Fig. 1. Correct Way of Planting Annuals or Bedding Plants.

Fig. 2. Wrong Way.

from a distance, and the appearance is gross in the extreme. Annuals and bedding plants should be 6–12 ins. apart at least, unless they are very small. Actual planting is done, as we said above, with a trowel (never with a dibber), the little plants being put into holes of just the correct depth and made very firm. Planting should not be done during hot sunshine.

Bulbs.—These too are planted with a trowel and never with a dibber. Bulbs can be set twice, thrice, or even four times their own depth in soil. As a rule bulb planting should be done in October, the earlier the better, and completed early in November. Great care is needed to see that the holes are flat at the bottom, since otherwise the bulbs may be hung, as is done if planting with a dibber is attempted. Make the soil firm. See our article on *Bulb Planting*.

Cabbages and Vegetable Plants.—As a rule these should be planted with a trowel and not with a dibber. The best period is a very showery day. Holes, or, in the case of brassicas, nicks, are made, the plants slipped in so that they are buried slightly deeper than before, and they are then made very firm. Planting in drills is advisable in the case of Cabbages and other similar crops; planting in richly manured trenches is advisable in the case of Celery, Leeks, etc.—in both cases to allow for earthing up. Planting on the surface is necessary in the case of Onion plants. See also the notes on Shallots in this article.

Fruit Trees.—These require careful planting. The soil is, of course, first trenched, and holes are taken out with the spade about 4 ft. square and 3 ft. deep. These holes are best dug some time in advance to save delay at planting time. The holes should be at least 9 ft. apart each way, and 12 ft. is better. The bottom of the holes is well loosened and a layer of good soil put in. The tree is then lifted into the hole (it must only be planted very slightly deeper than originally), and while one person holds the tree in an upright position the other fills in the hole and treads the tree very firm. On no account should a mulch of manure be put over the roots, round the stem, or anywhere near the trees, unless planting is not done at its proper time, November to February.

Perennials.—These are planted also with the spade. Holes are taken out which are amply large enough for the clumps, but not so deep that the crowns on the clump will be covered. The clumps are put in and the soil around them is made very firm. They may have to be firmed again after frost. Planting should be done from October to March. The distance apart varies according to the size and nature of the plants, from 9 ins. to 2½ ft. Planting of perennials is also referred to in the articles on *Herbaceous Borders*.

Potato Planting.—The wrong way of doing this is shown at Fig. 3 and the correct way at Fig. 4. In the

Fig.3. Fig.4
Wrong and Right Way of Planting Potatoes.

former diagram a dibber has been used and a great cavity left under the tuber. In the latter case, Fig. 4, the trowel has been the tool used, and the base of the potato rests on a level bottom. Potato planting is done from March to May, but, personally, we think March is too soon, for it often involves great risk of losing

the plants owing to frost. Potatoes are best planted 4–6 ins. deep in rows 18–36 ins. apart, the sets themselves being left 12–18 ins. asunder.

Roses.—The planting of these is dealt with in the article on *Rose Planting*.

Shallots.—These and onion sets require somewhat curious planting. The beds are prepared and the surface of these is beaten firm. Then the bulbs are put in so that they are only half buried, the distance apart being about 10 ins. each way from bulb to bulb. This planting is done in February or March.

Shrubs.—The sites for these are first of all thoroughly well prepared, and then, in the case of shrubs of good size, holes are dug about 2 ft. square and 2 ft. deep. The soil below is well broken up and thoroughly loosened. Then a layer of manure or peat is put into the bottom of the hole and covered with soil. After this, the shrub is put in with a big ball of its old soil on its roots if possible, as is shown at Fig. 5. The soil is then filled in round it and made very firm. No mulch should be given it until the following spring, if, as is advisable, planting is done in November. Tall shrubs and fruit trees ought to have stakes supplied to them not after, but during, the operation of planting, since the stakes can be set better then. If stakes are not supplied the trees will be badly blown about.

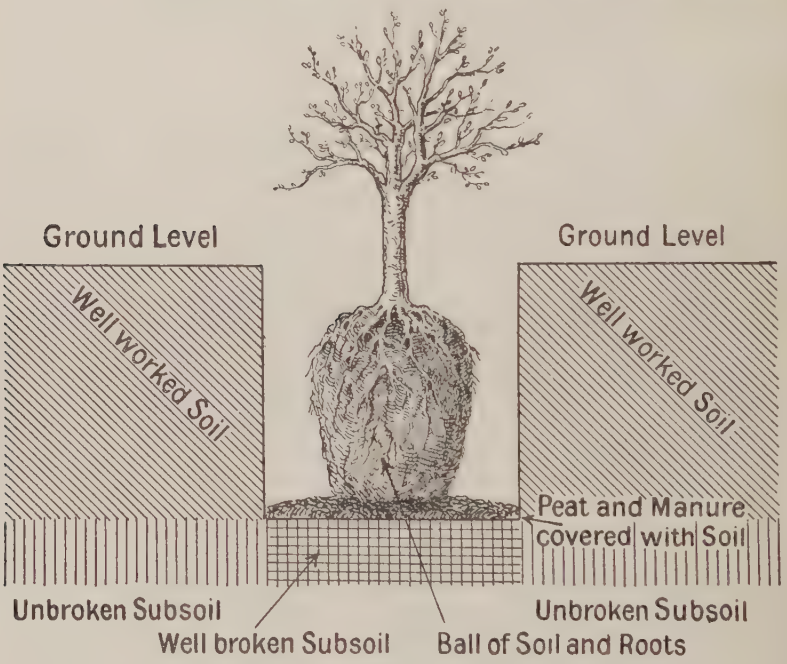

Fig. 5.

Trees.—We now come to the last of our planting subjects, namely, the planting of small and great forest trees. The latter point we do not propose to deal with, since it is beyond the skill of the ordinary gardener; and when it is required, which is but very seldom, competent

foresters should be employed. The planting of smaller types or specimens of trees is quite a simple matter. They should, if possible, have been re-planted several times in a nursery before being purchased, as this ensures them possessing a quantity of fibrous roots. Very large holes are dug out (sometimes they have to be nearly 5 ft. square, and may be anything from 3–5 ft. deep). Some good soil is put down in the bottom and then the tree put in the centre, securely staked and upright. It is necessary to get someone to hold the tree in position while you fill the soil in. This should be trodden down very well. Trees should not be mulched until the following spring.

Firm Planting.—This concludes our very brief survey of the subject of planting. Many other points might be dealt with, and some omitted from these notes are mentioned by contributors in the course of other articles. One point, however, would we reiterate, and that is the necessity of firm planting. More plants fail on account of loose, "flimsy" planting than through any other cause, so firm planting is one of the great golden rules of gardening.—E.

PLANTING BULBS.—See *Bulb Planting.*

PLANTING CLIMBERS.—See *Climbing and Trailing Plants.*

PLANTING DISTANCES FOR FRUIT TREES.—See *Fruit Culture, Hardy: General Considerations.*

PLANTING IN DRY WEATHER.—See Dry Weather Planting in *Bedding Out.*

PLANTING FRUIT TREES.—See *Fruit Culture, Hardy: General Considerations.*

PLANTING OUT VEGETABLES.—See under General Management in *Vegetables: General Considerations.*

PLANTING POTATOES.—See *Potato.*

PLANTING ROSES.—See *Rose Planting.*

PLANTING VIOLETS.—See *Violets.*

PLANTS: Packing.—See *Packing Flowers and Plants.*

PLANTS REQUIRED FOR DIFFERENT AREAS.—See under Volumes in *Arithmetic and Gardening.*

PLANTS: Training of.—See *Training of Plants.*

PLANTS or TREES: Law as to Removal.—See *Gardening Law.*

PLASTER FOR BACKING.—See *Mortar.*

PLATANTHERA.—Now included in the genus Habenaria.

PLATANUS.—For the best species see *Trees.*

PLATYCERIUM.—For the best species see *Ferns and Fern Gardening.*

PLATYCLINUS.—See *Orchids.*

PLATYCODON (Chinese Bellflower. Nat. Ord. Campanulaceæ).—Campanula-like plants of erect habit. Only one species is usually grown. This thrives in deep well-drained soil, and is propagated by division in spring, also by seeds in spring. It is a perennial with a tuberous root.

P. grandiflorum.—This produces tufts of erect stems with glaucous leaves. Flowers rich blue, very large. Site open. Soil deep loam. Flowering Period, July to August. Height, 2 ft. The varieties *album* and *Mariesii* produce white and blue flowers respectively. The last is of dwarf habit, growing 12 ins. high.

[It should be borne in mind that Platycodons are almost as much

border plants as rock plants, and should be more extensively grown in the borders than they are. For this latter purpose well-known double varieties such as *album plenum* (double white) and *plenum* (double blue) are the most showy. These are not suitable for the rock garden, as no one likes large double flowers there.—EDITOR.]

PLATYLANA.—Now included in the genus PELLÆA, for which see *FERNS AND FERN GARDENING.*

PLATYPAREA.—See ASPARAGUS FLY in *INSECT PESTS.*

PLATYSTEMON.—See *CALIFORNIAN POPPY.*

PLEASURE GROUNDS: Making and Management of.—The Pleasure Ground, as its name denotes, is that part of the Garden Department which has for its sole object the purpose of giving pleasure to its owner and his friends; therefore it is highly important that when making new or altering existing ones, the taste of the owners should be the first consideration, consistent with the ethics of Landscape Art.

In large establishments the usual procedure is to engage the Landscape Expert, and in such cases it will be seen that the larger the mansion, the larger the expanse of lawns, larger groups of trees and shrubs, etc.; in fact, the whole is proportionate to the size of the building. In some of the smaller establishments, the gardener is his own landscape artist, and it is well to bear in mind that anything that is disproportionate is wrong, and is not easily remedied, entailing an anxious time for the gardener in the future.

Having decided upon the extent of lawns, and the position of groups of trees and shrubs, the question arises: What trees and shrubs to plant to give the best effect?

Some Trees and Shrubs.—Only trees and shrubs of a known hardy constitution should be planted, and when given a bleak place should be protected from cold winds with spruce boughs or other suitable material. Cold winds are responsible for more deaths and sickly specimens than hard frosts, but the two combined are often fatal to newly planted trees and shrubs. Evergreens are great sufferers owing to their foliage giving a greater area for the wind to play upon, whereas with deciduous plants a certain percentage of wind passes through without injuring them.

In planting any of the Coniferæ choose a site where cold winds are broken up by a belt of trees or buildings. Among the most suitable of the Evergreens are Cedars, especially the beautiful *Cedrus atlantica glauca, Abies concolor,* and *Abies pungens glauca.* These trees never fail to find admirers—their silvery tint being very conspicuous.

The genus *Pinus* furnishes us with some very beautiful trees, some of which are indispensable—being of good growth, hardy, and stately. Other Evergreens worthy of a place are found among the *Rhododendrons, Osmanthus, Phillyraeas, Berberis,* Box (*Buxus*), Tree Ivies (*Hedera arborea*), *Retinosporas,* etc.

Although many of the Evergreens give very inconspicuous flowers, there is a great wealth of flowering plants to be found in the deciduous section. Their winter bareness is fully compensated for by their extreme beauty in the spring and summer; in fact, there are none so floriferous as these. What rivals have the *Magnolias, Forsythias, Spiraeas, Deutzias, Philadelphus,* Lilacs (*Syringa*), *Viburnums, Spartium, Azaleas, Ribes, Daphnes, Weigelas, Mespilus,* Cherries (*Prunus*), *Pyrus,* Almonds (*Amygdalus communis*), *Paulownias,* etc.?

Pergolas and Wall Plants.—The furnishing of Pergolas requires a considerable amount of judgment and care, and when judicially done is a pleasure to behold. It is desirable to select only known strong growers for this work, as the Pergola is somewhat different from the face of a wall, since it gets the wind from all quarters, hence the necessity for strong growers, and that they are securely tied. Most of the climbing Roses are suitable, also *Aristolochia Sipho, Azara microphylla, Ceanothus veitchianus, Ceanothus Gloire de Versailles, Clematis, Forsythias, Jasminum, Polygonum baldschuanicum, Vitis Coignetiae, V. Thomsonii, V. Thunbergii, Wistaria,* and the beautiful *Actinidia chinensis.* The last named is a very striking plant and a particularly strong grower—often growing 10 ft. during the first season—but is somewhat susceptible to injury by

spring frosts, as are the Clematis and Vitis. All three should as far as possible be planted on the most sheltered part of the Pergola.

A very common error with the pruning of plants on Pergolas is the production of a stiff close-pruned appearance. We much prefer to see the Clematis hanging in graceful festoons, and the Roses rising above the Pergola to give a more natural appearance. The case is different with wall-grown plants; these must necessarily be somewhat stiff, but even there it can be modified.

Planting.—This operation is of such importance that only the careful and experienced person who knows the requirements of the subject he is dealing with should be entrusted with the work. In opening the ground to receive its new occupant, the opening should not be less than 2 ft. wider than the radius of the roots when fully laid out, the subsoil loosened to a depth of 1 ft. and fresh compost added. The tree or shrub may then be planted, and if necessary secured to a firm stake—somewhat loosely at first to allow for a sinkage of the whole—and when finally settled the tree should be secured firmly.

Sometimes it is desirable to move a large tree, and when such is the case we prefer to prepare the tree for removal by cutting down and severing the roots on one half of the tree one year and the remaining half the next year. This operation ensures successful removal, and the tree grows away much more satisfactorily.

Evergreen Shrubs and Trees dislike winter planting, and therefore it is desirable to plant either in October or April, and with a ball of soil attached successful removal is practically assured. Deciduous trees are somewhat easier of management, but transplanting in the autumn is to be recommended, as the ground is warmer and root action takes place at once. During a hot, dry summer an occasional watering given to newly planted trees is of immense value. This should not be a mere surface watering, but a thorough soaking—one that will reach every root fibre.

Pruning of Shrubs.—This work calls for experience and thought. Some subjects require pruning immediately after flowering, examples of which are Rambler Roses, *Forsythias, Spiraeas, Jasminum nudiflorum,* and others, while such as *Ilex, Berberis, Amelanchier, Magnolia, Robinia, Cerasus, Chimonanthus,* and others only require such pruning as will preserve a well-balanced plant.

Flower Beds, Borders, Drives, Lawns, etc.—A trim and neat appearance of the Flower Beds, Borders, Walks, and Drives is always pleasing to the eye, and therefore it is essential that the edges of turf should be nicely and truly cut during the winter, and always cut in such a manner that the lower portion of the cut is inclined to the road or path. This gives solidity to the edges to better withstand the weight of mowing machines and rollers. Re-cut all Flower Beds and Borders in the same manner as the roads, and make a special point of seeing that all curves and lines are true.

Roads and Drives are better for being put in order during the winter, as the material binds better, and when done then does not interfere with spring and summer work. This is also the time for re-turfing any worn or bare places in the Tennis Courts, Bowling Greens, Lawns, Cricket Grounds, etc.

As the days lengthen the lawns will require attention in the matter of weeding and feeding. Remove all plantains and daisies; the former is the worst weed of all, for when removed it leaves an ugly bare patch. This can be remedied by loosening the soil and sowing grass seeds. Daisies are not so difficult if feeding is resorted to, as the stronger grass overgrows the daisies and suffocates them. Soot is invaluable to impart a beautiful green colour to the lawns, and has the advantage of being lasting. Many of the advertised lawn manures are useful, being scientifically prepared. They supply the exact food required. Rolling and sweeping prepares the way for the mowing machine, which is soon required.

Colour Harmony.—There is nothing in the flower garden so distasteful as a poor arrangement of colours; no matter how well the plants are grown, if the colour harmony or contrast is not well studied and carried out, the whole may be considered a failure.

Bold masses of a decided colour are preferable to mixtures, but where two or three colours are desired, aim at harmony. For guidance I will quote colours that harmonise with each other: Orange and Blue, Yellow

and Crimson, Yellow and Brown, Pink and Grey, Yellow and Purple, Pale Blue with light Orange, Scarlet and Green. White is good with any colour. Care should be taken not to use too much yellow, as this is a very telling colour and may easily be overdone. See also articles on *Colour Gardening*.

Staking, Thinning, and Tying.—What is there so ugly as a number of growths of plants tied up in "Birch Broom" fashion? Nature has taught us many lessons of how a plant should be, and one is to tie it in the position it was when about to fall out of place. Incline the stakes outwardly at a slight angle and put the stake in such a position that little or none of the stake can be seen. Some plants need no staking, being procumbent or semi-procumbent; leave these severely alone. Copy Nature as much as possible, consistent with needed support. See also *Stakes and Staking*.

Bedding and Border Plants.—There is a great diversity of colour and form among these plants, and it is not always necessary to employ much fire-heat to raise and grow them. Of late years the *Antirrhinums* have made such brilliant displays that it would be difficult to find any class of plant to surpass them in colour or ease of management. They seldom come true from seeds, therefore cuttings have to be resorted to; cuttings of any particular colour that it is intended to grow should be inserted in the ordinary way. The best varieties are: *Orange King*, 1½ ft. high; *Fire King*, 1½ ft.; *Golden Prince*, 2 ft.; *Nelrose*, pink, 2 ft.; *White Queen* 2–3 ft.; *Rosy Morn*, 2 ft.; and *Crimson King*, 2–3 ft. All these varieties will flower continuously from May to November provided all seed vessels are picked off as soon as formed.

Stocks are indispensable; their fragrance, long range of colour, ease of management, and general effectiveness mark them as among the finest of bedding or border plants that we have. Raised from seeds in boxes or frames and pricked out about 4 ins. apart at the end of April, they make sturdy plants to put into their permanent quarters, where they will flower onwards to November. Like the Antirrhinums, they dislike too much fire-heat—in fact, the less the better.

Numerous other plants require similar treatment, examples of which are: *Cheiranthus Allionii*, *Dimorphotheca aurantiaca*, *Gaillardias*, Larkspurs (*Delphinium Ajacis*), *Nemesia Suttoni*, *Phlox Drummondii* and its varieties, and a host of other plants, but such as Tagetes, Lobelias, Asters, Cosmos, *Dianthus Heddewigii*, Heliotropium, French and African Marigolds, Mimulus, Petunias, Pyrethrums, and Zinnias should be given a certain amount of heat to rear them in time to give a display, as described in the Half-Hardy Section of the article *Annuals for all Purposes*. See also article on *Bedding Out*.

Herbaceous Borders.—It is sometimes thought that these borders are places where plants may be put out to do their best with little attention. This idea is wrong. A well-arranged border needs a good deal of attention during the spring and early summer months, and well repays any care bestowed upon it. As, however, these borders have two special articles devoted to them, we refrain from giving subject details here.—J. W. M.

PLECTOCEPHALUS.—Now included in the genus *Centaurea*.

PLEIONE.—See *Orchids*.

PLEOCNEMIA.—Now included in the genus Nephrodium, for which see *Ferns and Fern Gardening*.

PLEOPELTIS and PLEURIDIUM.—Now included in the genus Polypodium, for which see *Ferns and Fern Gardening*.

PLEUROTHALLIS.—See *Orchids*.

PLOUGHMAN'S SPIKENARD (*Inula Conyza*.)—A wild plant of no garden value.

PLUM.—See *Plum: Culture of*, and under Prunus in article on *Trees*.

PLUM APHIS.—See *Insect Pests*.

PLUM (*Prunus*. Nat. Ord. Rosaceæ):

Culture of.—The culture of the plum is very similar to that of the apple, and this fruit may be successfully grown by carrying out the instructions in the general article on *Fruit Culture, Hardy*. Ordinary garden loam is all that is needed, since a rich soil means too much growth. Also extremes in soils do not suit it, for its roots will be chilled and starved in a strong clay soil and will wander about

hungrily and get very dry in summer if planted in a poor loose sandy medium. Suckers must be removed at an early stage; and young trees must not be allowed to be overburdened with fruit during the second or third year. Plums are propagated by grafting or budding. The principal stock used is the *Mussel*, but others, such as the *Myrobalan Plum*, the *St Julien*, and the *Brompton Plum*, also find favour. Root pruning, when carefully carried out in October, often results in a largely increased crop where trees were formerly inclined to "run to wood." On soils naturally deficient in calcareous matter a dressing of either ground chalk or quicklime should be applied every second season at the rate of 4–6 oz. per sq. yard; this will not be necessary where the soil rests on a limestone or chalk substratum.

PLUMS FOR DESSERT.

Of the four specially described below it is hard to say which is the best. The following is their order of ripening:—*Oullin's Golden Gage, Denniston's Superb Gage, Jefferson's Gage*, and *Late Transparent Gage*.

Denniston's Gage.—Small, yellow, often with red flush. Copious bearer, and good in any form. Delicious flavour.

Jefferson's Gage.—Large oval, yellow speckled and flushed with red. Growth compact, excellent in any form. Very delicious flavour.

Late Transparent Gage.—Small greenish yellow. Free bearer. Very rich flavour.

Oullin's Golden Gage.—Large clear canary yellow. Very rich and juicy. Free grower, and good in any form.

Other Sorts.—The following choice Dessert Plums are also of outstanding merit:—*Belgian Purple, Bryanston's Late Gage, Coe's Golden Dish Gage, Comte d'Althan's Gage, Golden Esperen, Kirke's Blue, Old Green Gage*.

PLUMS FOR COOKING.

Many of these when fully ripe rank for dessert use, especially when grown on a wall. Likewise Desserts are sweetmeats cooked.

Belle de Louvain.—Very large, egg-shaped. Colour deep purple. A grand thoroughly reliable variety succeeding in any form. Growth upright, and makes a fine tree. Rich acid flavour.

Late Orange.—Medium size, rich colour. A useful variety of free growth. Moderate bearer.

Pond's Seedling.—Very large, pink. A fine late variety. Makes a large tree and bears well.

President, — Large oval. Deep purple colour. Compact grower and good bearer. Rich flavour. A late variety.

River's Early Prolific.—Small oval. Deep purple colour. Ripens at the end of July. One of the richest for bottling or preserving. Makes a small weeping standard. Moderate bearer.

Victoria (*Alderton* or *Dampshine*). —Large pink. The well-known maincrop plum. Makes a small tree, and is good in any form.

Other Sorts.—The following Cooking Plums are also first class:—*Autumn Compôte, Cox's Emperor*, the *Giant Prune, Monarch, River's Czar, The Sultan*, and *White Magnum Bonum*.

The bottling of plums and other fruits is described in our article on *Fruit Bottling*.—G. B.

PLUM RED GRUB.—See *Insect Pests*.

PLUM RUST.—See *Diseases of Plants*.

PLUM WEEVIL.—See under Otiorhynchus Weevils in *Insect Pests*.

PLUMBAGO (LEADWORT. Nat. Ord. Plumbaginaceæ).—This is one of the best and most useful free-flowering plants grown for the greenhouse or conservatory, and for planting out of doors in the summer in mixed beds with other flowering and foliage plants. It is of easy culture, thriving in light sandy loam with one-third of fibre peat, and can be used as a pot plant, or climber to grow up pillars and rafters with good effect. Cuttings of side-shoots, or half-ripened young wood root freely in summer under a frame or hand-light, with little bottom heat. Temperature required from 50° F.

Greenhouse Species:—*Plumbago capensis.*—Pale blue. Flowers from June to October. Height, 2–10 ft.

P. capensis alba.—The white form. Flowers from June to October. Height, 2–10 ft.

P. Larpentae.—A hardy perennial rock plant. See *Ceratostigma plumbaginoides* in article on CERATOSTIGMA.

PLUME GRASS (*Pennisetum longistylum*).—See ORNAMENTAL GRASSES and PENNISETUM.

PLUME POPPY (*Bocconia.* Nat. Ord. Papaveraceæ).—Two kinds of Plume Poppies are commonly grown as hardy herbaceous perennials. These, *B. cordata* (Syn. *B. japonica*) and *B. microcarpa*, bear cream and bronzy flowers respectively from June onwards, and both have attractive foliage. The former averages 4–7 ft. in height, while the latter may reach a height of 9 ft. Light rich soil suits them, and propagation by root division in the early spring is not a matter of any difficulty. Their height and general character makes them suitable for shrub borders or for the back rows of hardy perennial parterres.

PLUTELLA.—See DIAMOND BACK MOTH in *INSECT PESTS.*

PNEUMONANTHE.—Now included in the genus *GENTIANA.*

POA (MEADOW GRASS. Nat. Ord. Gramineæ).—This is a large genus of hardy annual and perennial grasses. *P. abyssinica* is popularly known as TEFF. *P. annua* is the troublesome ANNUAL MEADOW GRASS, described with methods of control in our article on *WEEDS*, which is also known by the name of CAUSEWAY GRASS. *P. compressa* is known as the BLUE MEADOW GRASS, and is really a weed, though grown sometimes in the wild garden, while *P. nemoralis* and *P. trivialis* are useful lawn grasses, the former more especially for shady lawns and the latter for lawns in coast towns. (See article on *LAWNS AND THEIR MANAGEMENT.*)

POCOCKIA.—Now included in the genus *TRIGONELLA.*

PODOCARPUS.—For the best species see *TREES.*

PODOPHYLLUM (DUCK FOOT. Nat. Ord. Berberidaceæ).—Only three species of this are of much garden value. These, *P. Emodi* (Syn. *P. hexandrum*), popularly known as the HIMALAYA MAY APPLE, *P. peltatum* (Syn. *P. montanum*), the MAY APPLE, and *P. pleianthum*, are all hardy herbaceous perennials requiring a fairly moist soil, though they will grow, it is true, in dry borders or on rockwork. They bear white and purple flowers respectively from May onwards, and average ½–3 ft. in height. Propagation is best effected by root division in the spring, which is also the best planting period.

PODOSPERMUM.—Now included in the genus SCORZONERA. See *VIPER'S GRASS.*

POET'S DAFFODIL (*Narcissus Poeticus*).—See *NARCISSUS SPECIES.*

POET'S NARCISSUS.—The same as POET'S DAFFODIL.

POETICUS DAFFODILS. — See *DAFFODILS.*

POETRY.—See *GARDEN POETRY.*

POISON IVY (*Rhus Toxicodendron*) and **POISON OAK** (*Rhus Toxicodendron*). See *SHRUBS.*

POISON SUMACH (*Rhus venenata*).— See *SHRUBS.*

POISONOUS PLANTS.

A knowledge, even if it be only of a superficial character, of vegetation which is known to be more or less poisonous to human beings and to animals, is of very great importance to all gardeners. It is true that to be able to identify the majority of them the trained eye and skill of the botanist is necessary; but there are very many plants grown in gardens for their beauty that may be recognised without great difficulty; and while these may not be likely to be consumed in mistake by adults, there is always the risk of children or animals partaking of them with dire results.

Let us take, first of all, one or two crops grown for food, as examples which are particularly poisonous. Sorrel (*Rumex Acetosa*), which is sometimes used for salads, may not affect adults unless eaten to excess, but it often proves injurious to children because of the oxalic acid it contains. Rhubarb, again, is a perfectly safe vegetable to eat if its leaf stalks only be consumed, but if the leaves be cooked and eaten similarly to spinach, they are decidedly poisonous, as has been proved by comparatively recent cases. Here, also, the poisonous element is oxalic acid. Potatoes that have been long exposed to the light, and assumed a deep green colour in their skins, are also unsafe to eat because of the presence of a poison technically known as solanine.

Of fruits mention may be made of the kernels of the peach and nectarine and its ally, the Bitter Almond (*Prunus Amygdalus amara*), all of which contain prussic acid and are decidedly poisonous if eaten. Even the leaves of the Sweet Almond (*Prunus Amygdalus dulcis*) contain the same poisonous substance. Cases are recorded of children being poisoned by eating the kernels of cherry stones, so that it is well to warn young folk against doing so.

Many kinds of seeds of cultivated and wild plants are also poisonous. Those of the Laburnum (*Laburnum vulgare*) are especially so, and with these may be mentioned those of the Mulleins (*Verbascums*); the Corn Cockle of our cornfields (*Lychnis Githago*); the Spindle Tree (*Euonymus europaeus*); and of the Thorn Apple (*Datura Stramonium*). The seeds of the Monkshood (*Aconitum Napellus*) are also deadly poisonous, and so are those of its relatives, the Perennial and Annual Larkspurs (*Delphinium*). Seeds of the Castor Oil Plant (*Ricinus communis*) are poisonous to both man and beast.

Irritant poisons also exist in the foliage of such trees, shrubs, and plants as the Savin Juniper (*Juniperus Sabina*); Meadow Saffron (*Colchicum autumnale*); Hellebores (*Helleborus*); Yew (*Taxus baccata*); Arbor Vitae (*Thuyas*); the Common Laurel (*Prunus Laurocerasus*); *Andromeda polifolia*, and *Kalmia latifoila*. These are all highly dangerous to sheep or cattle partaking of them. Rhododendron foliage has also been known to poison live stock partaking of it. Nearly all the species of Ranunculus are poisonous to animals. Other species of wild flora which are poisonous to both man and beast are the Hemlock (*Conium maculatum*); Cowbane or Water Hemlock (*Cicuta virosa*); Water Dropwort (*Œnanthe crocata*); Fool's

Parsley (*Æthusa Cynapium*), a plant with parsley-like foliage and liable to be easily mistaken for the latter by inexperienced persons (a deadly poison); the Bitter-sweet or Woody Nightshade (*Solanum Dulcamara*); Dog's Mercury (*Mercurialis perennis*); Caper Spurge (*Euphorbia Lathyrus*); and the Box Tree (*Buxus sempervirens*).

The roots, bulbs, or tubers of many cultivated and wild flowers are known to be more or less poisonous to man and animals. Thus the roots of the various species of Monkshood or Aconite (*Aconitum*) grown in gardens have occasionally been mistaken for those of the horseradish or even for the tubers of the artichoke, with fatal results. Bulbs of the Daffodil or Narcissus; the Guernsey Lilies (*Nerines*); the Snowdrop (*Galanthus nivalis*); the Bluebell of our woods (*Scilla nonscripta*); and the Meadow Saffron (*Colchicum autumnale*) and its kindred species, are all of a poisonous nature, the Colchicums especially so. The corms of the Cuckoo-pint (*Arum maculatum*) are poisonous eaten in a raw state, but harmless when boiled. The roots of the Bryony of our hedgerows (*Bryonia dioica*) are also very poisonous. The fleshy roots of the Cowbane (*Cicuta virosa*), and of the Water Dropwort (*Œnanthe crocata*), have been known to poison animals who have partaken of them. The roots of the former have been mistaken for those of the Parsnip, also the leaves for those of the Celery, by human beings, with fatal consequences. Cases have occurred in recent years of animals being poisoned by eating the roots of the Runner Bean (*Phaseolus vulgaris*) that were carelessly thrown on a rubbish heap to which the animals had access. No doubt there are many more roots and bulbs that are unsafe for animals or human beings to eat.

Coming to berried fruits, those of the Yew (*Taxus baccata*) are more or less poisonous to children who have eaten them. The purple berries of the Privet (*Ligustrum vulgare*) have been known to poison children. The red berries of the Bryony (*Bryonia dioica*), so plentiful on hedges in late summer, are also exceedingly poisonous, fifteen of them being calculated enough to kill a child. The black berries of the Deadly Nightshade (*Atropa Belladonna*) are a deadly poison. So are the red berries of the Bitter-sweet (*Solanum Dulcamara*). Not less harmful are those of the Black Nightshade (*Solanum nigrum*). The so-called Wonderberry, a Yankee production, which was widely advertised a few years ago as an edible-berried plant, is unquestionably a variety of the latter, and hence should not be grown. The Caper Spurge (*Euphorbia Lathyrus*) produces seed-pods like those of the true Caper (*Capparis spinosa*), but as they are undoubtedly poisonous they should be avoided. Nor should children be permitted to eat the red berries of the Cuckoo-pint (*Arum maculatum*), or of the Mezereon (*Daphne Mezereum*), the well-known winter-flowering shrub.

Among other plants of a poisonous character, which have proved harmful to many persons by producing a kind of eczema or irritation of the skin, is the popular greenhouse plant called *Primula obconica*. The leaves and stems of this plant are furnished with hairs which are liable to penetrate the skin of the hands and arms when the plants are handled, and apparently discharge an irritant poison. In handling this primula, therefore, the gardener should wear gloves as a protection. Yet another plant

which has been extensively planted as a wall-climber under the name of *Ampelopsis Hoggii* possesses similar baneful properties. The correct name of this climber is *Rhus Toxicodendron*, commonly known as the Poison Ivy. Many people have been seriously injured by handling its leaves. Such a dangerous plant should be banished from our gardens. Some people have also suffered badly from blood poisoning through allowing the acrid milky juice which exudes from the cut shoots of *Euphorbia fulgens*, *splendens*, and *pulcherrima* to come in contact with open wounds on their hand when preparing cuttings. Even the hothouse species of *Allamandas* possess a similar property. In addition to these there are many fungi which are utterly poisonous to eat, and in some cases very dangerous to touch. These, however, are dealt with in the article on *Fungi: Edible and Harmful*.

Our list of plants that are poisonous to a smaller or greater extent does not by any means profess to be a complete one. It, however, contains those of the greatest importance which it is necessary for gardeners to make themselves acquainted with in order to avoid the possibility of serious illness or death following their consumption as food, or coming in contact with their bodies. Nor shall we attempt to give possible remedies here. In all cases it will be wise to secure medical assistance as promptly as possible in the event of illness occurring in connection therewith.—T. W. S.

POKEBURR (*Phytolacca decandra*) and **POKEWEED.**—See *Phytolacca*.

POLEMONIUM (Greek Valerian and Jacob's Ladder. Nat. Ord. Polemoniaceæ).—This is indeed a most desirable hardy herbaceous perennial. We have watched it growing for years in town gardens, and it thrives there quite as well as in our own garden, which may be said to be out of the town range. It is first class for cutting, though it is not everyone that is fond of its somewhat peculiar scent. It may be used alike in the herbaceous perennial border and in a sunny shrub border, or even in an open wild garden and rock garden.

Culture.—Undoubtedly this is a plant for the beginner or amateur gardener, for it succeeds admirably in any ordinary garden soil in a sunny position. Being one of the Phlox family, it is fond of plenty of water in very hot, dry weather. Planting may be done any time from late October to early April, and division of the roots may be carried out at the same period. The plant may be increased from seeds sown in the usual way for perennials, though division of the roots is obviously the quicker and more satisfactory way of increasing the stock. It is desirable that the dead flower spikes should be freely cut off if a second and autumnal supply of bloom is desired. We do not find it needs staking.

What to Grow.—We cordially recommend the following as desirable, easily grown species and varieties for the perennial border:—

Polemonium caeruleum.—Undoubtedly this is the most popular sort of all, and is deservedly the most widely grown. Its blue flowers are produced from June to August, and it averages 18 ins. in height. Some of the best sorts of this include *P. c. album*, a white-flowered sort; *P. c. dissectum*, similar; *P. c. pilferum*, a desirable blue; *P. c. Richardsoni*, of some nurserymen also blue, though what is most often popularly known as *P. c. Richardsoni* is really a variety

of *P. humile* below; *P. c. variegatum*, blue; and *P. c. villosum*, a desirable sky-blue.

P. flavum.—A pale yellow June and July flowering sort, growing up to 1 yd. in height, but seldom seen in ordinary garden borders.

P. gracile.—A blue early flowering sort opening its first blooms in early June. It averages about 18 ins. in height.

P. humile.—Nurserymen are responsible for confusing this species with others. By some it is known as *Polemonium Richardsoni*, which is, as noticed below, a variety of *Polemonium caeruleum*; by others it is known as *Polemonium moschatum*, though this is not really a species. It is a very dwarf blue midsummer or July flowering sort, growing not more than 6 ins. high.

P. mexicanum.—A blue spring (April) flowering sort about 1 ft. high.

P. moschatum. — A synonym, nursery name, or variety of *Polemonium humile*, which see.

P. pauciflorum. — This reddish-yellow summer blooming sort, which grows about 18 ins. high, is not specially desirable, though the colour is unusual.

P. reptans. — Useful in the rock garden. (See below.)

P. Richardsoni.—This popular sort of the nurserymen is considered by the Kew authorities to be a variety of *Polemonium humile* (which see), though a form of *P. caeruleum* is frequently sold for it.

P. sibiricum. — This, though offered as a species, is the variety *dissectum* of *Polemonium caeruleum*, which see.

P. villosum.—Often imagined to be a separate species, this sky-blue sort is in reality a variety of *Polemonium caeruleum*, which see.

Rock Garden Species. — These tufted plants are of easy culture, and are propagated by division in autumn or spring.

Polemonium confertum.—This biennial sort produces hoary pinnate leaves in tufts. Flowers deep blue, in clusters. Site, half-shade. Soil gritty, leafy, well drained. Flowering Period, June onwards. Height, 6–12 ins. The variety *melitum* has white flowers.

P. humile.—This (described above) is also suitable for the rock garden.

P. reptans.—This is of spreading habit. Flowers pale slaty-blue. Site, half-shade. Soil sandy loam. Flowering Period, March. Height, 9–12 ins.

POLIANTHES TUBEROSA. — See *TUBEROSE.*

POLISH WHEAT (*Triticum polonicum*).—See *TRITICUM.*

POLIUM.—Now included in the genus *TEUCRIUM.*

POLY GERMANDER (*Teucrium Polium*).—See *TEUCRIUM.*

POLYANTHA ROSES. — See *ROSE CLASSES.*

POLYANTHES DAFFODIL (*Narcissus Tazetta*).—See *NARCISSUS SPECIES.*

POLYANTHES NARCISSUS. — See TAZETTA and TAZETTA HYBRIDS in *DAFFODILS.*

POLYANTHUS (Nat. Ord. Primulaceæ).—Garden variety of *Primula vulgaris.* General description and culture are similar to those given in the article on *AURICULA.* As a florists' flower there are three sections, namely, Fancy, Laced, and Selfs.

Varieties.—The old named varieties are no longer in culture, and the plants are usually sold under the different sections. The *Munstead Strain* is the most famous.—J. L. G.

NEW VARIETIES.

Polyanthus Miller's Giant.—This bears extra large flowers, in shades of colour ranging from white to pink and crimson.

P. Orange King.—This bears deep orange flowers, which are edged bronze.

POLYGALA (Milk-wort. Nat. Ord. Polygalaceæ).—This is a genus of considerable extent, comprising hardy annuals, stove annuals, half-hardy evergreen shrubs, greenhouse evergreen shrubs, and hardy herbaceous perennial species. We need not trouble here with any but the last section; this, however, includes several species which may be grown in the usual way for hardy perennials in the mixed, shrub, or wild garden borders. Propagation is best effected by seeds sown in the summer or division of the root-stocks in the autumn or spring, at which latter period planting may be most successfully carried out. We recommend the following :—

Polygala calcarea (Chalk Milkwort).—This bears flowers of varying shades of purple, pink, rose, lilac, and blue. We understand there is a white form too, but have not yet grown it. The plant blooms from May to July, and averages 2–6 ins. in height.

P. Chamaebuxus (Bastard Box).—This, and its varieties *purpurea* and *rosea*, bear yellow, purple, and pink flowers respectively from May onwards, and grow about 6 ins. high.

P. comosa.—This bears pretty blue flowers from May to June, and averages 3–6 ins. high.

P. rosea.—This is a pretty species, bearing rose-pink flowers in May and June. It grows 3–6 ins. high.

POLYGONATUM. — See *Solomon's Seal.*

POLYGONUM (Knot Grass. Nat. Ord. Polygonaceæ).—Many plants are more useful than the Knot Grasses, it must be admitted, but without a brief reference to some few of the more attractive pecies this work would not be complete. The genus is a very large one, and contains hardy annuals, greenhouse evergreen shrubs, greenhouse herbaceous perennials, hardy herbaceous climbers, hardy herbaceous trailers, hardy herbaceous border plants, and hardy perennial rock plants. The first three sections are excluded from the present edition as being beyond our scope, while the best climbers and trailers will be found mentioned in our article on *Climbing and Trailing Plants*, although a couple are described under rock garden species below. Left, then, with the perennial border and rock plants, we may point out that the first are plants of extremely easy culture, more suitable for the wild garden or shrub border than for the perennial parterre. Common garden soil and a sunny or lightly shaded spot are alone the essentials to success; and propagation, a matter of extreme ease, may be effected by seeds sown outside from March to July, or by division of the roots from October to March, any time between which months forms a suitable planting period.

Perennial Border Species. — We mention the following as being the most noteworthy of the numerous species :—

Polygonum alpinum.—This and its varieties *polymorphum* and *songaricum* bear white flowers from June to July, and average 18–24 ins. in height.

P. amplexicaule (Syn. *P. petiolatum*).—This and its variety *oxyphyllum* produce red and white flowers respectively from mid-June onwards for six weeks, and average 1½–3 ft. in height.

P. angustifolium.—This nurseryman's species has now been renamed *P. Laxmanni.*

P. aviculare.—This, the Common Knot Grass, is not worth growing.

See KNOT GRASS in article on *WEEDS*.

P. baldschuanicum.—See article on *CLIMBING AND TRAILING PLANTS*.

P. Bistorta.—This is not worth growing save for medicinal purposes. See BISTORT in our article on *MEDICINAL HERBS*.

P. Convolvulus.—This is a troublesome weed, and not worth growing. See BLACK BINDWEED in article on *WEEDS*.

P. cuspidatum (Syn. *P. Sieboldi*).—This plant, on account of its foliage, is specially useful for the wild garden. It bears white flowers from June to September, and grows 6–12 ft. high.

P. divaricatum (Syn. *P. salignum*).—This spreading species bears white flowers from July to August, and grows 1½–3 ft. high.

P. Laxmanni (Syn. *P. angustifolium*).—This is a well-known and useful white June blooming sort, about 12 ins. high.

P. molle.—This is a white sort blooming from June to August, and growing about 1 yd. high. A sort of this name is described by another authority as being synonymous with *P. polystachyum*, which see.

P. multiflorum. See article on *CLIMBING AND TRAILING PLANTS*.

P. petiolatum.—Syn. *P. amplexicaule*, which see.

P. polystachyum. — This is a white sort blooming from July to September, and averaging 1 yd. in height.

P. sachalinense.—This, on account of its very handsome foliage, is specially useful in the wild garden. It bears white flowers from June to September, and grows 4–12 ft. in height.

P. salignum.—Syn. *P. divaricatum*, which see.

P. Sieboldi.—Syn. *P. cuspidatum*, which see.

P. virginianum.—This is a useful white August blooming sort about 1 yd. in height.

Rock Garden Species. — Only three species of this large family are suitable for the rock garden.

Two of these, *P. affine* and *P. vaccinifolium*, are valuable for covering large spaces. All are propagated by division of the roots in autumn or spring.

Polygonum affine (Syn. *P. Brunonis*).—This is a strong-growing creeper. Flowers rosy-pink. Site open. Soil sandy loam. Flowering Period, July to September. Height, 9 ins.

P. sphaerostachyum (Syn. *P. macrophyllum*).—This forms tufts of leathery leaves. Flowers blood-red in drooping spikes. Site shady. Soil boggy. Flowering Period, June. Height, 9 ins.

P. vaccinifolium.—This is a well-known trailing plant. Flowers rosy-pink in spikes. Site open. Soil sandy loam. Flowering Period, July to October. Height, 9 ins.

POLYPODIUM.—For the best species and varieties see *FERNS AND FERN GARDENING*.

POLYPODY.—The various forms of this are referred to under *Polypodium vulgare* in *FERNS AND FERN GARDENING*.

POLYPOGON (BEARD GRASS. Nat. Ord. Gramineæ).—This is a genus of hardy grasses which will grow strongly in most soils, but are hardly worthy of extensive cultivation even in the wild garden. The best species are *P. littoralis*, *P. maritimus*, and *P. monspeliensis*. These average 12 ins. in height.

POLYPORUS DISEASES. — See *DISEASES OF PLANTS*.

POLYSTICHUM.—Now included in the genus ASPIDIUM, which see in *FERNS AND FERN GARDENING*.

POMEGRANATE (*Punica granatum*). See *CLIMBING AND TRAILING PLANTS*.

POMPON DAHLIAS.—See *DAHLIA: CULTURE OF.*

POMPON ROSES.—See footnote to POLYANTHA ROSES in *ROSE CLASSES.*

POND MUD.

This is a fairly rich manure suitable for light soils mostly, but quite unsuitable for all soils in its fresh state. One of the best ways of treating it is to make a good heap of it, cover with soil to the depth of about 3 ins., and allow the material to mellow down for about a year. It can then usually be cut down into shreds or a rough powder and spread on the land. About 2 cwt. per square rod is usually very ample, and the best time to apply is the late autumn or early winter.

PONDWEED.—See *POTAMOGETON.*

POOR MAN'S WEATHER GLASS (*Anagallis arvensis*). — See *ANAGALLIS* and under SCARLET PIMPERNEL in *WEEDS.*

POPLAR.—For the best species see POPULUS in *TREES.*

POPLAR GALL APHIS.—See under LETTUCE ROOT APHIS in *INSECT PESTS.*

POPPIES (*Papaver.* Nat. Ord. Papaveraceæ).

Annual Species.—Very few of the so-called ANNUAL POPPIES are of strictly annual duration, although their tendency is in this direction after many years of cultivation and selection as such. Notwithstanding the fugitive character of their flowers they are prime garden favourites, while for indoor decoration, when cut in the opening-bud stage, they are charming. In cultivating the sorts named below it should be remembered that with very few exceptions the seeds are sown far too thickly and the seedlings are insufficiently thinned out. The novice may consider it foolish to thin the popular Shirley Poppies until the seedlings are 1 ft. apart, and yet it is only thus that the full beauty of the plants may be obtained. All Poppy seeds are small, and in most cases they are freely produced, the usual result being thick sowing. Annual Poppies dislike transplantation, therefore the seeds should be sown where the plants will remain to flower. Good garden soil gives the best results; in very light, dry, and poor soils Poppies have only a short life. The seeds should be sown in the autumn or early spring, merely covering them with soil, but of course the site should be carefully levelled or the hoe may put an end to their existence ere they are fairly through the soil. After the thinning out above mentioned, a copious watering should be given. We recommend the following species:—

Papaver glaucum (TULIP POPPY).—This has deep red flowers and blooms from June onwards; it is very effective when massed, especially in mixed borders. Its height averages about 18 ins.

P. pavoninum (Syn. *P. cornigerum*).—This, the well-known PEACOCK POPPY, is a handsome, scarlet-flowered species, with a black blotch at the base of each petal. It blooms throughout the summer, and averages 18 ins. in height.

P. Rhoeas (Syns. *P. arvaticum, P. arvense, P. cereale, P. cruciatum, P. rusticum,* and *P. umbrosum*).—This is the common SCARLET POPPY or FIELD POPPY, often so beautiful (but a bad weed) in cornfields. There are numerous strains, but the SHIRLEY POPPIES are probably the most popular, with a range of colouring from palest pink to crimson, and from cream to heliotrope, while the flowering period extends from June to October. The Japanese Pompon strain is 15 ins. high, and has double flowers. Some of the Shirley Poppies are

semi-double, and others are double, but not clumsily so. The height of the Shirley Poppies is about 2 ft.

P. somniferum (Syns. *P. album, P. amoenum, P. amplexicaule, P. officinale,* and *P. setigerum*).—This is the OPIUM POPPY famous in China, and a plant that is naturalised in Great Britain. It is extremely variable, and a number of varietal forms have been named, while garden strains are also numerous. The blooms are large; they are set on stout, many-flowered stems above wavy, greyish leafage. Most of the large, very double and fringed forms offered by seedsmen have been evolved from this species, and the colour of the blooms may be white, blush, rose, lilac, violet, red or crimson. The *Carnation, Danebrog, Mephisto, Mikado,* and *Paeony-flowered* strains, as well as *Cardinal* and *White Swan* varieties, have all come from *P. somniferum.* The flowering period of these extends throughout the summer, and the height is 2–4 ft. For the medicinal culture of this plant see OPIUM POPPY in our article on *MEDICINAL HERBS.*

Perennial Border Species.—This section of Poppies is a very extensive one, to which it is difficult to do justice. All the species are of easy culture, thriving under the usual treatment given to hardy herbaceous perennials, but must be well staked, otherwise the taller sorts fall about rather badly, and look distinctly untidy. They prefer moist and rich garden loam containing plenty of sand, and are not difficult to propagate in the autumn or spring by root division, at which times they may be successfully planted. It may be well to remark that they do not love being disturbed, and should certainly not be lifted more than once in three years. A mulch of old hotbed manure will be useful for keeping the roots of most of these species (especially *P. nudicaule* and *P. orientale*) moist in dry weather. This should be put on in mid-June. Of the large numbers of species we recommend the following:—

Papaver aculeatum (Syn. *P. gariepinum*).—This bears bright, almost vermilion, red flowers from June onwards, and averages about 18 ins. high.

P. caucasicum (Syns. *P. floribundum* and *P. fugax*).—This bears attractive red or crimson flowers from June to July, and averages 1½–2½ ft. in height.

P. nudicaule (Syn. *P. radicatum*).—This, the ICELAND POPPY, is, of course, a very well-known garden plant, bearing useful yellow flowers from July onwards on plants 1–2 ft. in height. There are some garden varieties of this, including two or three dwarf forms suitable for rockwork, averaging only 6–12 ins. in height.

P. orientale.—This species includes the well-known ORIENTAL POPPIES, of which there are such hosts of garden varieties at the present time. The colours are mostly reds, while the flowering period extends from May to June, and the height averages 2½–4½ ft. Space taken up here in describing the best sorts would be wasted, as new improved sorts are constantly being put on the market. Readers should thus consult current trade catalogues.

P. radicatum.—Syn. *P. nudicaule,* which see.

Rock Garden Species.—Only a few species of Poppies are suitable for the rock garden, of which the two given below are quite the best. Both succeed under ordinary rock garden or rock border culture in well-drained loam, and are best propagated by seeds sown very thinly in the autumn.

Papaver alpinum (Syns. *P. Burseri* and *P. pyrenaicum*).—This, popularly known as the ALPINE POPPY, an annual or biennial, has much divided greyish foliage in tufts. Flowers vary from white to orange and pink. Site open. Soil very gritty. Flowering Period, July. Height, 3 ins.

P. nudicaule.—The dwarfer forms of this, as mentioned in the last section, may be used in the rock garden with considerable success.

NEW VARIETIES.

Papaver nudicaule Sunbeam Strain.—This has large flowers on long stems, the colours being mostly shades of orange and yellow, also white.

P. orientale bracteatum King George.—This has orange-scarlet flowers deeply fringed.

P. o. b. Lady Frederick Moore.—This has large salmon-pink flowers with black blotches.

P. o. b. Perry's Pigmy.—This has cup-shaped salmon flowers with dark blotches, and grows only 18 ins. high.

POPPY ANEMONE (*Anemone coronaria*).—See *ANEMONE.*

POPPY MALLOW (*Callirhoë.* Nat. Ord. Malvaceæ).—The Poppy Mallows are not very hardy, but as they are plants of distinct beauty, many would be sorry to dispense with them. There are both annual and perennial forms, but in the notes below only the latter are described. These may be grown in the usual way for hardy perennials, in light, rich garden loam in a sunny site, save for the fact that winter protection is desirable. Propagation may be effected in the usual way by seeds and division of the roots, also by cuttings of young growth about June or July. We recommend the following:—

Callirhoë alcaeoides (Syn. *C. macrorrhiza*).—This is available in many colours, including red, rose, carmine, purple, pale pink, and white. It blooms from July to August, and grows 12 ins. high.

C. involucrata.—This is a most attractive sort, bearing vivid red flowers from July onwards, and growing about 6 ins. high.

C. macrorrhiza.—Syn. *C. alcaeoides* above.

C. Papaver.—Probably this is the most popular species of all. It bears violet-red flowers from July to August, and averages 1 yd. in height.

POPPY, OPIUM.—See OPIUM POPPY in *MEDICINAL HERBS.*

POPULUS.—For the best species see *TREES.*

PORCUPINE GRASS (*Stipa spartea*).—See *STIPA.*

PORE CLOSING.—The meaning of this term is explained under TRANSPIRATION in *PLANT PHYSIOLOGY.*

PORRUM.—Now included in the genus *ALLIUM.*

PORTLAND SPURGE (*Euphorbia portlandica*).—See *EUPHORBIA.*

PORTUGAL CABBAGE.—See *COUVE TRONCHUDA.*

PORTUGAL LAUREL (*Pinus lusitanica*).—See *TREES.*

PORTUGUESE HEATH (*Erica lusitanica*).—See *HEATHS.*

PORTULACA.—See *ANNUALS, HALF-HARDY: LIST OF; PURSLANE, ANNUAL;* and under PURSLANE in *SALAD PLANTS.*

POST OAK (*Quercus stellata*).—See *TREES.*

POT CULTURE OF CARNATIONS.—See *CARNATIONS.*

POT MARIGOLD (*Calendula officinalis*).—See *MARIGOLD.*

POT MARJORAM (*Origanum Onites*). See *ORIGANUM.*

POT PLANTS: TOP-DRESSING FOR.—See *TOP-DRESSING.*

POT SIZES.

Various names are given to different-sized pots which prove puzzling to uninitiated amateurs, so we give a list below of the names of the various sizes with the measured diameter :—

Thimbles .	2	ins.	across the top.
Thumbs . .	2½	,,	,,
Seventy-twos	2½	,,	,,
Sixties . .	3	,,	,,
Forty-eights	4½	,,	,,
Thirty-twos	6	,,	,,
Twenty-fours	8½	,,	,,
Sixteens . .	9½	,,	,,
Twelves . .	11	,,	,,
Eights . .	12	,,	,,
Sixes . . .	13	,,	,,
Fours . . .	15	,,	,,
Twos . . .	18	,,	,,

The last three sizes are very seldom used. There is no popular name for a 5-in., 8-in., or 10-in. pot.—E.

POT VINES.—See *VINES.*

POTAMOGETON (PONDWEED. Nat. Ord. Naiadaceæ). — This is a large family of hardy aquatic perennials which grow under water in ponds, etc. They are of easy culture, but of little value, bearing only insignificant greenish flowers in June and July. The best known species are *P. densus,* the WATER CALTROPS, and *P. natans,* also known as the TENCH WEED. *P. crispus* and *P. lucens* (Syn. *P. acuminatus*) are also sometimes grown.

POTASH and POTASH COMPOUNDS. See *POTASH AND POTASSIUM COMPOUNDS.*

POTASH MANURES.—See *MANURES,* and *POTASH AND POTASSIUM COMPOUNDS.*

POTASH AND POTASSIUM COMPOUNDS.—Potash in some form is essential for all forms of plant life ; it is the keynote of successful gardening, and if its need was more fully realised there would be very many fewer failures. As a general rule potash is used as a fertiliser, but there are one or two striking exceptions to this rule, as we shall see.

Forms of Potash.—Should the gardener glance down a chemical list he will note "Potash—see Potassium," and when he refers to potassium he will find that there are more than sixty different forms of it. Of these, however, only a few are useful to him, and these are briefly dealt with below. As regards natural forms of potash, we may point out that Kainit is rich in it, but besides the sulphate of potash which it contains there is also a good deal of salt and magnesium chloride. Clay soils are rich in potash in an insoluble form ; to release this, such soils should be thoroughly trenched and heavily dressed with freshly burnt ground quicklime. Wood Ashes also contain it (see the article on *ASHES : THEIR VALUE IN THE GARDEN*). Animal manures all contain varying quantities of it, and some guanos, such as Fish Guano ; also poultry manure and seaweed both contain it.

Application of Potash.—Impure forms of potash which may contain injurious chemicals should be applied in the early winter to allow the weather to act upon them and wash out their impurities. A fact not generally known is that soils cannot hold potash unless chalk or some form of lime is present. This is probably the reason why certain gardeners can see no beneficial results accrue after an application of potash—naturally there are no benefits if the material has been washed out of the soil. There are very few plants which do not repay well a dressing of potash, but if it is scarce, it should in preference be given to crops such as beet, carrots, onions, parsnips, potatoes, potato onions, and salsafy, also to fruit trees.

We will now say a few words about the different potash compounds.

POTASSIUM CARBONATE is the first compound on our list. In its impure state it is what is commonly known as POTASH or PEARL-ASH. If it is boiled with lime and the liquid filtered and evaporated, caustic potash (Potassium Hydroxide, which see) results. Carbonate of potash, as it absorbs water very readily and is very caustic, is not much used in the garden, but it can be used as a dressing for rose beds and the general garden at the rate of 1–2 oz. per sq. yd. so long as it is dug in in the early winter.

POTASSIUM CHLORATE.—This is not used as a fertiliser but as an oxidising agent. It can be used to help with the burning out of wasps' nests, or for giving a good start to the burning of sulphur in greenhouses.

POTASSIUM CHLORIDE or MURIATE is another little used compound of potash. So long as it is applied in the autumn and at the rate of 1–2 oz. per sq. yd., it will be found a good fertiliser for vegetables generally, also fruit trees and herbaceous plants. It is never advisable to apply it in the spring as it has a deleterious effect on seedlings and small plants.

POTASSIUM CYANIDE.—This is a deadly poison and used for making hydrocyanic acid for fumigating. See HYDROCYANIC ACID under the title *ACIDS: THEIR USES IN HORTICULTURE*. None of this salt should be left lying about.

POTASSIUM FERRO-CYANIDE can be used for testing the presence of iron in soils. Dilute hydrochloric acid is poured over a sample of soil and stirred. Excess of acid is neutralised with carbonate of soda, and then some dilute ferrocyanide of potash poured in. If iron is present a change of colour takes place.

POTASSIUM HYDROXIDE.—This is caustic potash. It is a frequent ingredient of winter washes for fruit trees, and can, as described above, be made from carbonate of potash. As the hydroxide burns holes in clothes and flesh, care should be taken in handling it. The pure chemical, which will probably arrive in the form of sticks, should be kept in tightly lidded pots or tins, otherwise it will absorb water from the atmosphere and dissolve therein.

POTASSIUM MURIATE is the same as the *Chloride*, and has been dealt with under this heading.

POTASSIUM NITRATE is an expensive manure but well worth its cost. It is as quick a manure as nitrate of soda (see *SODA AND SODIUM COMPOUNDS*), and a better manure in every way since it supplies potash as well as nitrogen. It should contain about 40 per cent. of potash, and 12½ per cent. of nitrogen. As a stimulant, it is almost unrivalled. It can be used at the rate of ¼ oz. per gallon of water occasionally during the summer to growing flowers and crops. Potassium Nitrate is also known as Saltpetre or Nitre—it is quite distinct from Chile Saltpetre. There are nitre beds in India. Some of it can be obtained by purifying the drainings from manure. Nitrate of potash is often adulterated. Common salt, which is similar in appearance, is the chemical most often used for this purpose. Gardeners can tell, however, whether it has been thus adulterated by dissolving an ounce or so in a little water, and adding a small quantity of silver nitrate solution. If salt has been used to adulterate it there will be a white compound formed in the liquid which will fall to the bottom. This is silver chloride.

POTASSIUM PERMANGANATE.—This is little used by the gardener. A tiny crystal can be put into the water of cut flowers to keep it pure. It is largely used for giving soil fumigants their dark colour. Experiments with permanganate as a remedy for wart and other diseases of crops have failed to prove it useful.

POTASSIUM PHOSPHATE.—This compound is very soluble in water and highly valuable as a fertiliser. It is a stimulant of first-rate merit for nectarines, peaches, tomatoes, and other glasshouse fruits; for sweet peas and exhibition flowers; for culinary peas, runner beans, onions, and other vegetable crops. Unfortunately it is expensive and difficult to get, but manure makers should realise that were a supply put on the market at a cheap rate there would be no lack of purchasers for it. Phosphate of potash absorbs water readily, so should be kept in air-tight tins or pots. It is not applied as a "land dressing" but as a summer stimulant. One-quarter ounce per gallon of water occasionally will be quite enough.

POTASSIUM SILICATE.—The form of this which comes to the gardener is dilute water-glass, after it has been used for preserving eggs in the kitchen. This material is not of great value, but it can be spread out in a thin layer on light soils and dug in during the winter.

POTASSIUM SULPHATE, or sulphate of potash, is the well-known potash fertiliser, so we need not say a great deal about it here. It can be used as a land dressing at the rate of 1–2 oz. per sq. yd. in the spring, and again in the summer, working it well in. It increases the quality of all crops, but is specially good for tuberous and tap-rooted vegetables. It can also be used as a summer stimulant at the rate of 1 oz. per 2 gals. of water occasionally. Sulphate of potash should dissolve completely in water. If it will not, then it is impure and should be rejected.

POTASSIUM SULPHIDE.—The active ingredient of Liver of Sulphur is Potassium Sulphide, a chemical unpleasant in its use but highly effectual as a fungicide. It is used at varying strengths, from 1 oz. in 10 gals. of water to 1 oz. in 3 gals. of water. Soft soap is often added. This solution ruins white paint in greenhouses, and should not be used unless the gardener has been told that zinc paint instead of lead paint has been used for such structures. References to this sulphide, liver of sulphur, are made in the article on *Spraying Mixtures* to which the reader is referred for further information.—E.

POTASSIUM SULPHIDE.—See *Potash and Potassium Compounds* and *Spraying Mixtures and Fungicides*.

POTATO (Type: *Solanum tuberosum*. Nat. Ord. Solanaceæ).—Thanks to the accommodating nature of this, no matter where planted, one is pretty certain of getting at least a satisfactory return for the outlay. In fact, so accommodating is this that, providing a change of seed is obtained every second season, profitable crops may be taken every year from the same plot of ground without following the usual Rotation of Crops thought by many to be so necessary with many other vegetables.

[Our contributor is quite correct in his assertion that the above may be done. But we should never advise this to be carried out where a Rotation was possible. We are of the opinion that Rotation should be much more adopted than it is. Unless care is taken to avoid growing "similar" varieties as a change of

seed, the crops will soon be reduced. The potato, even though such a common well-known vegetable, deserves good treatment such as is recommended by our contributor below; and we have always found it well repays any trouble bestowed upon it.—EDITOR.]

Where quality combined with quantity is desired, good drainage is of great importance; if this is lacking, not only will the tubers when cooked be of a soapy nature, but in a wet season even the reputed disease-resisting varieties will be found to be very badly affected; and what appear to be perfectly sound tubers, will show signs of decay after being in store a short time.

Preparation of Land.—Soils inclined to be pasty or which work badly, should be very liberally treated with road-sidings, burnt turf, or ashes from a garden smother, while if a few loads of old builders' rubbish can be had cheaply, a dressing of this will not only bring the soil into better working condition, but have a marked beneficial effect upon the quantity of the crop.

The ideal potato soil is a good loam in a high state of fertility, brought to this state by continuous manuring, and proper aeration by early winter preparation.

Even the most fertile soil will be all the better for a moderate application of manure; and although very good results may follow the use of one of the well-known "prepared manures," still better are assured by using these with a fair amount of animal manure.

Where it can be obtained, manure from a mixed farmyard is undoubtedly preferable to that from any one class of animals; and it is important that this should be used in a well-rotted state. Potatoes grown upon land manured with nearly fresh dung are apt to run very much to leaf, and the tubers will be scabby. As a guide to what may be termed a fair dressing of manure, soils of a very hungry or sandy nature should have not less than two good barrow loads applied to each square rod of ground, and half as much again would be even better. Heavy soils are best manured as early in the year as possible, but others of a sandy nature may be left until a short time before planting.

If the dressing of manure advised is supplemented at the time of planting, or after the tops of the potatoes are a few inches above the soil, by a dressing of one of the popular "complete potato manures," or each square rod given a dressing of the following home-made mixture, a good crop of medium to large-sized tubers is assured:—

FORMULA: POTATO MANURE.

Superphosphate of Lime	2½ lb.
Sulphate of Ammonia	¾ lb.
Sulphate of Potash	3 lb.

This should be kept well off the tops and be immediately stirred into the surface with the hoe.

Planting.—The advantage of planting well-sprouted seed sets is now fully recognised, and wherever possible, steps should be taken to secure each set being well chitted at the time of putting in the ground.

The size of sets is really not so important as many would have us believe; although in our opinion the ideal size is that suggesting a bantam's egg, or weighing about 2½–3 oz., it must be confessed we have lifted wonderful crops resulting from planting sets much larger, also much smaller than these; while the fact that heavy crops are taken each year by those who plant single eyes shows the absurdity of laying down any hard-and-fast rule. It all depends upon the state of the soil, the season, and the source from

which the "seed" was obtained; we have frequently proved a 3-oz. set from the home-raised crop will give a far lighter crop than one but half its weight purchased from Ireland or Scotland; Lincolnshire-grown seed giving good results in most soils, particularly those of a heavy nature.

The number of shoots, or chits, these sets are allowed to carry must be determined by the size of the tubers the grower is most anxious to secure. One shoot per plant usually means very large tubers; two shoots per plant medium tubers; three or more, a mixed crop, but very few above the ordinary size.

Non-sprouted early varieties may be planted in a warm border in March, but any time from early March until the end of April will be soon enough for the maincrop or late varieties. Well-sprouted sets, carrying good healthy shoots an inch long, should not be planted in cold soils until quite the end of April, or an unexpected frost may delay if not completely ruin the crop. [In the North the planting of unsprouted tubers is not wise before 15th April, and all planting is considered quite early enough if completed by the third week in May.—EDITOR.]

Plant with a garden trowel, or, better still, get out trenches 6–8 ins. deep with a spade or the corner of a good hoe, and carefully lay the tubers in these at the proper distance apart, covering with fine soil. Sets planted in this manner grow away very rapidly and well repay the extra trouble.

For the early varieties which are less robust in growth than others, 15 ins. between the rows and 1 ft. between the sets will be ample; but when planting others which do not complete their growth until August or September, 2 ft. must be allowed between the rows, or where it is intended to plant winter greens between the potatoes while these are still growing, nothing less than 30 inches or even more between the rows is advisable.

After Cultivation. — When the plants are well through the ground, the earth on either side of the runs should be drawn up to them in order to prevent the tubers produced near the surface becoming green through exposure to sun and air. Where doubts are entertained regarding the fertility of the soil, it is when the plants have reached this stage that additional help may be given in the shape of the fertilisers above mentioned.

Spraying as a preventive against disease has much to recommend it, and one is pleased to find the practice becoming pretty general. The time to commence is when the tops are about a foot above the soil; a second spraying being given in a fortnight's time; and should dull, muggy weather prevail, a third spraying will be labour and money well spent.

There are so many excellent spraying compounds now on the market all of which may be depended upon to be perfectly safe to use even by inexperienced persons, that the purchase of these is recommended in preference to any home-made mixtures. But whatever is used, care must be taken to wet the underside of every leaf thoroughly, this being more important than the tops. [See also article on *POTATO BLIGHT*.—EDITOR.]

The early crop should be ready for lifting from the middle to the end of June, a trifle later in some districts and some seasons; late or main crops may be lifted as soon as the tops die down in the autumn.

Storing may be done either in cool sheds, cellars, or what are known as potato pies, or clamps; in every case the chief object must be to prevent

light reaching the tubers, and at the same time to secure against frost. [See *Vegetables: Harvesting and Storing*.—Editor.]

Varieties :—*First Early*.—Eclipse, Harbinger, May Queen, Midlothian Early, Ninetyfold, Ringleader, Sharpe's Express, Sharpe's Victor, and Witch Hill Seedling.

Second Early.—British Queen, Epicure, Snowball, Snowdrop, The Admiral, Windsor Castle.

Maincrop or Late Varieties.—Arran Chief, Colleen, Crofter, Dalhousie, Drummond Castle, Factor, Golden Wonder, Irish Queen, Irish Wonder, King Edward Seventh, Queen Mary, Rob Roy, The Chapman, and The Provost.

F. R. C.

[For important sorts which are similar, if not indistinguishable except in name, the reader should refer to the Board of Agriculture's List of Wart Disease-resisting Potatoes published in December or January each year.—Editor.]

New Varieties.[1]

Below we describe some of the very best, but the notes, especially as regards the shape, are only approximately correct, on account of the fact that the sorts have not been long in commerce. The following abbreviations are used :—*C.K.* for coloured kidney ; *C.O.* for coloured oval ; *C.R.* for coloured round ; *W.K.* for white kidney ; *W.O.* for white oval ; and *W.R.* for white round :—

America (*W.R.*).—This is an early sort, with spreading haulm. The eyes are of medium depth.

Arran Comrade (*W.R.*).—This is a second early sort, with upright or slightly spreading haulm. The eyes are shallow.

Arran Rose (*C.O.*).—This is an early sort, with strong haulm and shallow eyes.

Burnhouse Beauty (*W.R.*).—This is a second early sort, with strong haulm and shallow eyes.

Culdees Castle (*W.O.*).—This is a maincrop variety, with strong, spreading haulm. The eyes are shallow.

Dominion (*W.R.*).—This is a maincrop sort, with vigorous and somewhat spreading haulm. The eyes are shallow.

Gordon Castle (*W.R.*).—This is a maincrop variety, with strong, bushy haulm and shallow eyes.

Kerr's Pink (*C.R.*).—This is a maincrop variety, with tall, upright haulm, and medium to very deep eyes.

King Albert (*W.R.*).—This is an early maincrop sort, with strong, upright haulm and shallow eyes.

Majestic (*W.K.*).—This is a maincrop variety, with medium and spreading haulm. The eyes are shallow.

Mauve Queen (*C.R.*).—This is a maincrop variety, with medium and upright haulm. The eyes are of fair depth.

Nithsdale (*W.K.*).—This is a maincrop sort, with medium and spreading haulm. The eyes are shallow.

Secundus (*W.O.*).—This is an early maincrop sort, with strong, upright haulm and shallow eyes.

Stirling Castle (*W.R.*).—This is a second early sort, with vigorous haulm and shallow eyes.

The Bishop (*W.O.*).—This is a maincrop variety, with medium and spreading haulm. The eyes are shallow.

The Duchess (*W.R.*).—This is a second early variety, with moderately vigorous, spreading haulm, and eyes of medium depth.

The Lochar (*W.R.*).—This is a maincrop variety, with upright or

[1] Excepting *Gordon Castle*, *Stirling Castle*, and *Warwick Castle*, all are immune to Wart Disease.—Editor.

spreading haulm. The eyes are faintly tinged with pink and are of medium depth.

Tinwald Perfection (*W.K.*).—This is a maincrop sort, with medium spreading haulm and shallow eyes.

Warwick Castle (*W.R.*).—This is a second early sort, with strong, upright haulm, and shallow eyes.

W. J. C.

POTATO: The Ally.—In a potato-growing contest in 1919 a Sheffield allotment holder lifted a crop of this variety which amounted to 29⅝ tons per acre, over 200 lb. being yielded from half a stone of seed. This weight is a record, and was obtained by planting the seed whole in land dressed with flue dust, a little animal manure being put above the sets. The Ally is an inexpensive, early maincrop variety of excellent flavour, and a good keeper.

POTATO BLIGHT (*Phytophthora infestans*).—This, the most destructive of all potato diseases, is caused by the microscopic fungus named *Phytophthora infestans*, which not only attacks and blackens the haulm but also destroys the tubers. In 1845 it devastated the potato crop in Ireland, causing widespread suffering, and ever since that date has been recognised as a serious menace to potato growing.

The disease starts as a rule in June or July, when the well-known black patches appear on the leaves accompanied by the delicate white mould on the under surface. It is the presence of this white or grey mould around the affected areas which distinguishes Blight from black spots on the leaves caused by aphides and other agencies. If the weather be damp and warm the disease spreads rapidly, plant after plant becoming affected and the haulm blackened and destroyed. If, on the other hand, the weather turns dry the disease is checked, in fact the intensity of attacks of Blight in this country are almost entirely dependent on the nature of the season. It is, of course, by means of spores that the disease is distributed. These are produced on the white mould seen on the affected leaves; they are readily carried by rain, wind, insects, etc., from plant to plant, and if the climatic conditions are favourable they germinate and cause new patches of disease from which innumerable fresh spores are liberated within the course of a few days.

The disease in the tubers is the result of the presence of the fungus in the leaves. Spores fall in profusion from affected leaves, and finding their way to the tubers present in the soil, readily infect them. Those tubers nearest the surface are naturally most seriously affected. A large amount of infection also takes place whilst the potatoes are being lifted, spores being blown from diseased haulms on to the tubers. The tubers at the time appear to be and are healthy, but the spores germinate and infect them, and later on the effect is seen by decay in storage.

The infection of tubers can be easily detected by the presence of dark, depressed areas which it will be noted are usually on the upper surface. Inside the tubers the result of the fungus invasion is seen in the formation of the well-known brownish-red patches. Spore infection so far as is known is the only way by which tubers become affected. No scientific support has been found for the theory formerly held that the mycelium of the fungus passes down inside the haulm and along the rhizomes into the tubers.

The rapidity with which decay

takes place varies with the time of year and differs also in different varieties. In some varieties decay is slow, in others, such as *British Queen*, very rapid rotting may suddenly occur during autumn when tubers have been clamped. During the winter and spring, however, a large amount of decay takes place amongst all varieties through the spread of the disease in the flesh of tubers which were infected by spores during the previous summer and autumn.

The initial outbreaks of disease at the beginning of the season arise in the following manner. A certain number of affected tubers remain tolerably sound till spring. If these are planted as "sets," some die, others give rise to healthy plants, whilst a few produce, in addition to healthy shoots, a few dwarf diseased shoots on which spores are sooner or later developed. It is these shoots which are the initial source of infection, and under favourable weather conditions they infect surrounding plants. The outbreaks of disease each season are traceable to the use of diseased sets, a few of which, as stated above, give rise to diseased shoots. The tubers may often be only very slightly affected and hardly noticeable. It is therefore evident that it is impossible to prevent such cases occurring, and they do in fact all over the country both in gardens and fields. Outbreaks of Blight must accordingly be regarded as inevitable, and energies should be concentrated in checking its spread and preventing damage. Amongst minor methods may be mentioned the allowance of a liberal amount of room between the rows, careful and thorough earthing up, and the removal of the haulm when once it is badly diseased.

Spray Your Potatoes.—The best preventive of Blight is, however, a good spray, such as Bordeaux or Burgundy Mixtures. See article on *Spraying Mixtures and Fungicides* for methods of making these solutions. The spraying mixture covers the leaves with a protective covering of the copper compound, and spores alighting on this film cannot produce the disease. Spraying does not entirely prevent the disease, since it is obviously impossible to cover the leaf surface completely, still less does it destroy it when once the fungus is within the tissues; but according to carefully conducted experiments it does, if applied properly and thoroughly, very materially *reduce* the amount of infection in the foliage, and consequently loss of crop. In addition it often increases the crop by prolonging the growth of the haulm.

Spraying should begin early in July for the greater part of England, and somewhat earlier in the south-west. It may be left to the last week in July for the north-eastern counties. A second spraying should be given three weeks after the first, and in most seasons a third is desirable; in fact, it is often the third spraying which saves the crop. If severe rain follows any one spraying, the operation must be repeated. Spraying should not be done, if possible, under a very hot sun, as scorching is apt to follow. The amount of mixture required for ¼ acre is 30 gals., or 7½ gals. per 10-rod plot. For the second and third spraying a somewhat larger amount will be required. For the proportions of chemicals required and the instructions for mixing, see article on *Spraying Mixtures and Fungicides*.

Whilst spraying is theoretically sound and is practised extensively and regularly in many parts of the country with marked success, it is undoubtedly true that the operation

does not always yield the increased crop which one would expect. In many cases, moreover, scorching is complained of. The explanation of the non-success is sometimes difficult to arrive at, but at other times the cause of failure is easily discoverable and may be obviated if more care be exercised. Scorching, for instance, is usually brought about through some kind of faulty application of the mixture (*e.g.* improper preparation, use in a stale state, or application in very hot sunshine), but it also occurs in the neighbourhood of manufacturing towns and cities as a result of the influence of town smoke and where plants are attacked by Aphis.[1] In large industrial areas, therefore, such as parts of Lancashire and Yorkshire, it is doubtful whether spraying is a profitable operation.

Another frequent cause of apparent non-success of spraying is lack of care at lifting time. Tubers which have been preserved from Blight by spraying are left exposed to windborne spores after lifting (see above), or covered with potato haulm, a most unwise practice. The *most* important factor, however, is the nature of the weather during and after spraying time. The ideal time to choose is two or three days before the wet spell, so that the spray may have time to dry thoroughly, but as no grower can predict the weather with certainty, there is always an element of chance. In some seasons the fates seem against one. Rain may wash off the mixture before it dries, and while the grower is waiting in vain for a fine day, Phytophthora gets a hold and does its deadly work.

For many counties of England it is still an open question whether spraying is or is not worth the trouble and expense, and only carefully conducted experiments lasting over several years can settle the question. The future may have in store varieties altogether immune to Blight, in which case this troublesome operation may cease, but for the present it is advisable to do what one can to secure the crop against waves of disease by means of a careful and thorough spraying.

Potato Blight on Tomatoes.—Tomatoes both out of doors and under glass are often attacked by Potato Blight, the spores from diseased potato haulm passing to the Tomato and causing infection. Indoors the disease may appear fairly early (July), but outdoors it occurs chiefly from the beginning of September onwards. Both foliage and fruit are attacked, the former showing the white mould as in the potato, and the latter becoming mottled with brown markings and turning rotten. A large quantity of green fruit outdoors is annually lost late in the season by the Blight fungus.

REMEDIES. — Tomatoes outdoors should not be planted nearer maincrop or late potatoes than necessary, and should be sprayed with Burgundy or Bordeaux Mixture in July and August. Under glass fire heat

[1] In some potato-spraying experiments conducted by the Editor in an industrial city during the summer of 1918, clear evidence of scorching being due to smoke fumes was obtained. It was found, however, that the plants sprayed with Bordeaux Mixture were hardly scorched at all, hence the advisability of using this mixture as preferred to Burgundy Mixture in such cases. Various preparations of soap, some of which had been widely advertised, were tried; these did not result in any scorching, but did not keep down the Blight. Where Aphis is troublesome on potato haulm it is advisable to spray with quassia and soap (see article on *INSECT PESTS: General Methods of Destruction*) first, and to follow with the usual spraying mixture a few days later.

and ample ventilation, so as to produce a dry atmosphere, will usually dispel the disease, but spraying should be resorted to as a preventive if potatoes are grown near to the house.—A. D. C.

POTATO BLIGHT ON TOMATOES.—See *POTATO BLIGHT*.

POTATO DISEASES.

[The following notes on diseases of the humble "spud" will be useful to readers in addition to the previous article on *POTATO BLIGHT*. —EDITOR.]

Black Leg or **Black Stem Rot** (*Bacillus phytophthora* and others). —This disease, which is conveyed in the "seed," is common and at times does much damage. It shows early in the season from June onwards, producing stunted plants with yellow leaves. The stems become black at the base and rot away and are easily pulled up. This blacking of the stem is characteristic and gives its name to the disease. Tubers of affected plants become soft and rotten, decay taking place at once or later on when the tubers are stored.

REMEDY.—Diseased plants should be marked, dug up, and destroyed in summer; the sound tubers may be eaten, but not kept for seed. Sound seed should be procured, if possible, only from a source known to be free from disease. Infected land should not be planted with potatoes for at least a year.

Black Speck, or **Rhizoctonia Scab** (*Rhizoctonia Solani*).—The specks or black bodies formed on the skin of potato tubers by this fungus, though often very conspicuous, are in reality of little consequence. They can be scraped off with the finger nail, leaving no mark, and do not injure the flesh. The fungus in Europe does little harm, though occasionally it injures the young shoots, and if the specks are present in quantity it spoils the appearance of the tubers. The fungus is so generally present in the soil and does so little harm that control measures, even were they feasible, are unnecessary.

Common Scab, Brown Scab, or **Land Scab** (*Actinomyces sp.*).—This exceedingly common affection of potato tubers is particularly abundant in small gardens and old allotments, especially where ashes, road sweepings, and lime rubble have been applied. The scab is now known to be due to the micro-organism *Actinomyces*, which is favoured by the presence of these substances, and not to the irritating action of the substances themselves as was formerly thought. The scabbing is confined to the surface layers of the tubers, and affected potatoes are often of good eating quality.

REMEDIES.—Scabbing is favoured by alkalinity of soil, therefore the acid-forming manures sulphate of ammonia and superphosphate of lime should be used in preference to others. In small gardens flour of sulphur (1 oz. to sq. yd.) is useful. Badly scabbed tubers should if possible not be used for "seed" as the eyes are apt to be weakened.

Corky or **Powdery Scab** (*Spongospora subterranea*).—In a mild form corky scab forms small round pimples on the skin and is comparatively harmless; in bad cases it produces large cankerous wounds. It is worst on wet and ill-drained soil and is favoured by the use of lime. The disease is more common in the Midlands and in the North than in the southern counties.

REMEDY.—Tubers with corky scab should preferably not be used for seed, but if dipped in dilute formaline solution for ninety minutes (½ pint to 15 gallons of water) they may

safely be planted. Wet ground should be avoided or properly drained, and acid manures such as sulphate of ammonia and superphosphate of lime given instead of nitrate of soda or basic slag. Lime should be avoided, but in small gardens flour of sulphur applied at the rate of 2½ oz. per sq. yd. is useful.

Dry Rot (*Fusarium caeruleum*).—A storage rot of the tubers, and prevalent from December onwards, increasing with the approach of spring, hence also known as **Winter Rot**. Early varieties are most susceptible. The fungus causes depressed areas in the tubers often surrounded with concentric zones and bearing white or pale pink pustules, masses of spores. Later the tubers become hard and dry.

REMEDY.—Though wounds are not essential, they greatly assist the entry of the fungus. Great care, therefore, should be exercised when digging and handling seed potatoes, especially early varieties. Affected tubers should not be used for seed. Diseased tubers cannot be saved. The storage place should be cool and well ventilated, and the stores frequently examined (if Dry Rot is likely to develop), and all diseased potatoes at once removed and burned.

Leaf-curl. — The potato plants affected by this disease are characterised by an upward, inward roll of the leaflets, an erect, rigid appearance, some stunting of growth, and the frequent occurrence of red, purple, or yellow coloration. The trouble is worse on dry lands and in dry seasons. The cause is still rather obscure, and so far in England the damage has not been so great as on the Continent and in the United States. The yield, however, from affected plants is decreased and the tubers run small.

REMEDIES.—Seed from good stock (preferably from a northern source rather than a southern or dry district), good cultivation, and the rotation of crops are all that can be recommended.

Sprain.—Potatoes that on the outside are apparently sound sometimes show rusty brown streaks and specks of dead spongy tissue when cut open. The trouble has been known, though rarely, to be faintly indicated also on the outside. The cause of this disease remains obscure. It occurs on dry, sandy soils, especially if lacking in lime, and is rare on strong, heavy soils. It is most frequent in the north of Great Britain, and is more prevalent in a dry season. No remedy other than avoiding the above predisposing conditions can be recommended.

Wart Disease of Potatoes (*Synchytrium endobioticum*).—Wart Disease, Black Scab, or Cauliflower Disease is a most serious menace to potato growing. It causes great loss of crop, and is exceedingly difficult to eradicate. The fungus, which lives in the soil, produces abnormal outgrowths on the potato, resembling warts or pieces of cauliflower. These are at first white, but become black. The tuber may lose all likeness to a potato and become a mere mass of excrescences, which presently rots away, leaving the spores of the disease in the soil. Occasionally the lower leaves are affected. The disease is easily conveyed from one district to another by means of contaminated soil and contaminated seed-tubers, and, once infected, soil remains capable of producing the disease for years. Hence great care should be exercised in the distribution of seed tubers.

REMEDY.—There is only one remedy known, namely, the planting of immune varieties. A list of

these can be obtained from the Board of Agriculture. Wart Disease is notifiable under the Destructive Insects and Pests Acts, 1877–1918, and outbreaks should be reported to the local authority or to the Board of Agriculture.—A. D. C.

POTENTILLA (CINQUEFOIL.[1] Nat. Ord. Rosaceæ). — Certainly the hardy perennial species of this include some of the finest of all flowers, glorious alike for border and house decoration. The flowers last well when cut, and are most attractive.

Culture.—The plants thrive well in ordinary light garden soil in a sunny position. Plant any time from November to March, and give abundance of moisture in dry summer weather. They may easily be propagated by seeds or division of the rootstock, the former method of increase taking place in spring or summer, and the latter in late autumn or early spring.

Perennial Border Species.—Below is a selection of desirable sorts :—

Potentilla alchemilloides.—A white species blooming throughout the early summer, and suitable alike for the margins of borders and rock garden. Height, 6–9 ins.

P. arguta.—A light yellow species blooming in June and July. Height, 9–12 ins.

P. argyrophylla.—A yellow species blooming from June to September. Height, 1–2 ft.

P. a. atrosanguinea.—This is the *Potentilla atrosanguinea* of the nurseryman. Its dark crimson flowers are well known. It will usually bloom the whole summer, and in height it is about 1 ft.

P. atrosanguinea.—See above.

P. formosa of nurserymen. See *P. nepalensis.*

P. fruticosa.—A yellow species often grown as a shrub and not as a herbaceous perennial. It blooms in July and August. Height, about 3 ft. ; sometimes more.

P. grandiflora.—A fine yellow species with larger flowers than some. It blooms from June to September, and its height is 1 ft.

P. hopwoodiana.—A species often offered by the trade, but not so good as some. Its flowers are rose and white and it blooms freely in June and onwards. Its height is about 1½ ft.

P. hybrida.—There are a great many hybrid named varieties which are first class for the perennial border. Improvements are rapid, and it will be best for readers to consult hardy plant specialists on what to buy, as any list given here would soon be out of date.

P. laciniosa.—A yellow June flowering variety of *P. recta* about 2 ft. high.

P. nepalensis.—A fine blush-pink species, with dark crimson centre, blooming in July, August, September, and October. Height, about 1½ ft. Miss Willmott's variety is dwarfer.

P. pensylvanica.—A yellow summer flowering species about 1½ ft. high.

[1] The SILVERY CINQUEFOIL (*P. argentea*) ; the SILVER WEED (*P. Anserina*) ; and the TORMENTIL (*P. Tormentilla*) are not much grown in gardens.

P. pyrenaica.—A deep yellow species, flowering freely most of the summer. Height, about 15 ins.

P. recta.—A yellow June flowering species, quite useful. Its height is about 1 ft.

P. rupestris.—A white species blooming in June. Height, 1½ ft.

P. russelliana.—A useful hybrid variety. Its flowers are of a rich dark scarlet colour and freely produced in the summer. Height, about 1 ft.

Rock Garden Species. — These number a dozen or more. They thrive in well-drained soil in sunny situations. All are perennials, and are propagated by division in spring.

Potentilla ambigua.—This forms dense masses of evergreen foliage. Flowers rich yellow. Site sunny. Soil sandy loam. Flowering Period, June to August. Height, 4 ins.

P. nevadensis.—A dwarf compact plant. Flowers yellow. Site, open. Soil gritty. Flowering Period, May to July. Height, 4 ins.

P. nitida.—This forms dwarf mats of silvery ternate leaves. Flowers pale rose. Site sunny. Soil gritty. Flowering Period, June to September. Height, 3 ins. Its variety *alba* has white flowers, but is otherwise similar.

P. splendens.—A sort forming spreading tufts of grey leaves. Flowers white. Site sunny. Soil gritty. Flowering Period, May to August. Height, 9 ins.

P. tridentata.—This forms carpets of green foliage. Flowers white. Site, half-shade. Soil sandy loam. Flowering Period, June to September. Height, 3 ins.

P. villosa.—A sort forming small tufts of silky-haired leaves. Flowers yellow. Site sunny. Soil gritty. Flowering Period, June to August. Height, 6 ins.

See also *SHRUBS*.

POTERIUM (Syn. *Sanguisorba.* BURNET. Nat. Ord. Rosaceæ).—Nearly a dozen species of this genus, most of them of comparatively small value, are grown at Kew. All are hardy herbaceous perennials, some of which are of weedy appearance, and all thrive with great freedom in ordinary common garden soil. They may be propagated by seeds and division of the roots at the usual times, and planted any time between October and March. We recommend the following :—

Poterium alpinum.—This is a purple sort blooming from July to August, and growing about 2 ft. high.

P. canadense.—This is probably the choicest species. Its white flowers are borne in July and August, on plants about 1 yd. in height.

P. tenuifolium. — This and its variety *album* bear purple and white flowers respectively from June to August, and average nearly 1 yd. in height.

NEW SPECIES.

Poterium obtusum. — This bears bright rose flowers on branching spikes 2–3 ft. high.

POTHERBS.

All the ordinary sweet or savoury herbs of the kitchen garden, besides being of use for seasoning, have a value in medicine, chiefly for the sake of their aromatic and disinfectant oils. The majority of the Potherbs belong to the Labiate Order. As a general rule all can be propagated by cuttings or by division of roots. The culture for all is along very similar lines, although some require moist soil, and some dry, while others seem to do well in any spot. In many cases the beds require to be made afresh every year.

Marketing.—This is quite simple. Potherbs should be tied in bundles of equal size and length and hung up

to dry in a warm current of air out of the sun, and protected in some way from dust. When the leaves are quite brittle they can be stripped from the coarser stems. The herbs should be stored or packed in air-tight containers, otherwise they will reabsorb moisture from the air, ferment, become discoloured, and spoil.

We give below notes on all the important Potherbs:—

American Horse Mint (*Monarda punctata*. Nat. Ord. Labiatæ).—This is the source of Thymol, one of the "stearoptenes" or solid volatile oils. It is a handsome Labiate plant much like the better known Bergamot (*Monarda fistulosa*) of the garden border. Any good soil suits it, and propagation is easily effected by cuttings. The whole herb is used.

Balm (*Melissa officinalis*. Nat. Ord. Labiatæ).—This will thrive in any ordinary garden soil, and is easily propagated by cuttings. Remake beds annually.

Basil (*Ocimum Basilicum*. Nat. Ord. Labiatæ).—A tender exotic annual, which must be raised from seed in heat. Sow in April, prick out into boxes to strengthen, and plant out about 1 ft. apart in June on beds of rich, light soil. Lift the herb in September, and pot in warm greenhouse for the winter.

Calamint (*Calamintha officinalis*). —This is grown in the same manner as BASIL. For garden culture and other species see separate article.

Catmint (*Nepeta Cataria* or *N. Mussini*).—For herbal culture see BASIL, and for garden culture and other species see separate article.

Clary (*Salvia Sclarea*). — This with Catmint and Calamint is a herb of the Labiate Order. Its cultivation and treatment are practically the same as BASIL.

Garden Mint.—The culture of this is similar to that of PEPPER MINT, which see.

Hyssop (*Hyssopus officinalis*). Nat. Ord. Labiatæ).—This easily grown herb prefers friable soil, and is propagated by dividing roots in spring or by raising from seed in April.

Lavender (*Lavandula vera*. Nat. Ord. Labiatæ).—This is the source of Oil of Lavender. The herb is cultivated for its fresh flowering "tops," and is an easy plant to grow. It will succeed in any friable garden soil, and can be propagated by division in spring, or by cuttings of young wood set in free sandy soil under hand-lights in autumn, and planted out in spring in their permanent positions. These cuttings should be placed in well-prepared ground 12–15 ins. apart, in rows 3–4 ft. asunder. An ordinary soil will yield 600–1200 lb. per acre of flowering tops. The lavender bushes should be kept low and compact, and not allowed to run to straggling wood, to the detriment of the blossom and flower-bearing power of the plant. The beds should be remade every three or four years. Full crops can be taken from the second to the fourth year, but earlier or later than this they are not in finest condition. Lavender is one of those herbal crops which require to be grown, if for commercial purposes, on a rather extended scale.

Marjoram (*Origanum Marjorana*. Nat. Ord. Labiatæ).—A light, rich soil is required for this plant, which can be grown from seed or propagated by cuttings. Sow under glass in April, harden off, and plant out in May 6 ins. apart each way.

Mint.—The culture of this is similar to that of PEPPERMINT below.

Pennyroyal (*Mentha Pulegium*. Nat. Ord. Labiatæ).—Treat in the

same manner as PEPPERMINT. It will grow in nearly any sort of soil. The oil of this herb has commanded from 7s. to 9s. per lb.

Peppermint (*Mentha piperita.* Nat. Ord. Labiatæ).—A perennial propagated by division of roots or by cuttings. Beds require remaking every second year. All mints will do well in a sandy soil if sufficiently moist, and can be grown on stiff loam or clay in damp meadows or paddocks, though they require to be kept clear of weeds. Cuttings should be taken when the shoots are about 3 ins. long, each with a piece of root attached. These should be laid in rows or shallow trenches about 9 ins. apart, leaving the green tops above ground. The herb is cut when in flower in August.

Rosemary (*Rosmarinus officinalis.* Nat. Ord. Labiatæ).—This is a shrubby perennial plant. The flowering shoots are the parts required. It can easily be propagated by cuttings, and does well in almost any situation, but succeeds best on somewhat light soils. The beds do not require to be remade.

Rue (*Ruta graveolens.* Nat. Ord. Rutaceæ).—A familiar kitchen garden perennial, which flourishes in any well-drained soil, but which succeeds best in soil of a chalky nature. It is used in homeopathy and by the herbalists, but would not repay for growing on an extensive scale in this country (unless some measure of protection were to be afforded to the British herb industry), since it flourishes wild all along the shores of the Mediterranean, and can be more cheaply imported. Rue can readily be propagated by cuttings struck in autumn or spring, and accorded the protection, for a short time, of a hand-light. The plants should be set about 15 ins. apart, and cut back from time to time. They last for some years. The fresh young shoots or "tops" are the part required, and should be cut and dried in July.

Sage (*Salvia officinalis.* Nat. Ord. Labiatæ).—A perennial which is liable to be destroyed by frost or damp. Plant in a sheltered position in well-drained soil, preferably of a calcareous nature. As close cutting is likely to injure the herb, propagate from seed sown in April, or from a few cuttings set in a cold frame in September. The plants should stand 2 ft. apart, and the beds be remade every three years. Frequent harvests of leaf can be taken.

Savory (*Satureia hortensis* and *S. montana.* Nat. Ord. Labiatæ).—Sow seed in shallow drills about 9 ins. apart in mid-April, thinning out seedlings to 6 ins. apart in the rows, and treat as for MARJORAM.

Spearmint.—The culture of this is similar to that of PEPPERMINT, which has already been given.

Tarragon (*Artemisia Dracunculus.* Nat. Ord. Compositæ).—This may be easily propagated by division of roots or grown from cuttings. It thrives in light, rich soil, but requires dividing and replanting each year in April if on damp or heavy land. It is a perennial herb, and is harvested in August or September.

Thyme (*Thymus vulgaris.* Nat. Ord. Labiatæ).—This is one of the sources of Thymol, and the plant needs a warm position as well as good soil. It is propagated by seed sown thinly under glass or by cuttings set about 1 ft. apart when transplanted to their permanent position. The plants require constant division to keep them rich and bushy. New beds should be made annually.

Woodsage (*Teucrium Scorodonia.* Nat. Ord. Labiatæ). — A fairly

common plant growing in coppices and on hedgerows and hillsides which has pale yellow characteristically Labiate blossoms. We recommend it to the herb grower's attention. Treat as for SAGE.

A. B. T.

[For careful identification and description of all the wild and native Labiate herbs generally, see *Flowers of the Field*, by the Rev. C. A. Johns, or other similar botanical works.—EDITOR.]

POTPOURRI.

What is Potpourri? the uninitiated English amateur will ask, and in a word it may be said to be the essence of every delightful scent in a handy solid form. It is made in two different ways: by a dry method and a moist. The first is easiest and quickest, but by the moist process the result is better, sweeter, and more enduring.

In the dry method the Rose petals are completely dried; preferably on sheets of paper in an airy room. The Lavender and Sweet Geranium leaves and any other ingredients are also made quite dry.

In the moist process the material is only partly dried, so that it has a tough, leathery consistency; it is then put into a well-glazed jar, a good handful at a time, pressed down, and sprinkled with a salt mixture, consisting of equal parts of bay salt and common salt. The bay salt, which is sold in lumps, is roughly pounded, so that some of it is quite small and some the size of peas, and is mixed with the common salt.

Materials.—The usual materials for potpourri are—Rose petals for a good half or more of the whole bulk, sweet or scented Geranium, Sweet Verbena, Bay leaves, and Lavender. If a preponderance of Rose petals is secured the exact proportions of the rest do not matter; the supply is sure to vary from year to year. Anything may be added which has a lasting fragrance from possessing some kind of essential oil.

How to Make.—If the potpourri is made on rather a large scale it is convenient to prepare the different ingredients in separate jars. But everything is treated alike in being put into the jars, salted and pressed. The layers should be about ½ in. thick after pressing, and the salt over each layer should be enough to show evenly all over without actually covering. It is important that the Roses should be picked when free from rain or dew; they should be just full blown, but not overblown; the petals are picked off and separated, and laid out in a room to become half dry. No definite time can be given for this, but it usually takes from two to three days. The leaves of the Sweet Geranium are torn into strips, and take about as long to dry as the Rose petals. Bay leaves, Lavender, and Sweet Verbena have less natural moisture; they can go straight into the jars without any special drying. The material is not only pressed down in the jars as it goes in, but must also be weighted down by means of a wooden disc that nearly fits the inside of the jar, and a stone or other weight; the wooden presser may have to be in two pieces if the jar narrows at the neck. When all is ready, a mixture of spices and sweet gums is prepared; a suitable quantity for a bulk of two-thirds of a bushel would be: Mace, cloves, and cinnamon, half an ounce each; coriander, allspice, gum storax, and gum benzoin, half an ounce each, all pounded; and violet powder, a quarter of a pound. The prepared Rose petals will be found to be in close, flaky masses that must be carefully broken up by hand and well mixed up with all the rest and with the spice mixture. The same spice mixture is used for both kinds of potpourri.—G. J.

POTTING.

The ideal soil for potting is the top spit from good pasture land. It is usual to cut this in turves about a foot square, and from 2–5 ins. thick according to the amount of fibre it contains, and then stack them on slightly raised ground, grass side downwards. In six or eight months it will be ready for use, and may be chopped down with a spade. Second in importance is leaf-mould. It is impossible to have too much of this material in hand, as it mixes freely with the soil and lightens it, acting also as a mild manure, encouraging a healthy root action. Oak and Beech leaves make the best mould

after they have decayed sufficiently to be passed through a sieve following a gentle chopping with a spade. Coarse and fine sand, together with old lime rubble, wood ashes, and charcoal, are always more or less necessary to make a good porous compost. Many of our brightest winter-flowering greenhouse plants come under the heading of hard-wooded plants. These must have peat; ordinary soil is no use to them, and anything in the shape of lime is fatal. For orchids also a special compost is required in the shape of sphagnum moss and osmunda fibre mainly. It is not intended here to go into details of compost, but the grower will naturally use his own judgment in this way. For very young plants and such as only produce very fine roots, as, for instance, primulas and winter-flowering begonias, he will use a compost finer in every case than he would employ in the final potting of chrysanthemums, tomatoes, and other vigorous-growing plants that will take a compost which can be got ready almost with the aid of a spade only.

Having got clean pots, see they are well provided with drainage. Broken pieces of pots usually provide this; and oyster shells are useful for very large pots. The use of bones, or anything similar, is not advisable, as they do not always achieve the desired object, frequently becoming rank and sour. One good piece of pot over the hole in the bottom of the pot is sufficient for the smaller sizes, but for 5-inch pots and upwards an inch deep of finer pieces will often be needed to ensure perfect drainage. As a rule the limit is reached with fine-rooted subjects, rather less being employed for those with a vigorous root action. Immediately over the crocks put a thin layer of the roughest of the compost in order to prevent the finer portions from being washed down, and impeding the free outlet of waste water; a handful of compost then slightly beaten down with a rammer will make it ready to receive the ball of the plant to be potted. To knock this out of its pot, turn it upside down in the left hand, and with the aid of the right give the edge of the pot a slight tap on the edge of the bench, when it will come away easily and intact, representing in a healthy plant a ball of roots. Remove the old drainage and the loose top soil, then gently place it in the centre of its new pot, care being taken not to bury the stem any deeper than before, and gradually fill in with the new soil, using the potting stick carefully as the work proceeds, until the pot is filled to within half an inch of the top. Some plants require a firmer rooting medium than others, and thus need a freer use of the potting stick; for instance, a sandy soil should be made firmer than a clayey one. Also certain plants require a very loose rooting medium; for instance, carnation roots will revel in a compost that would be almost fatal to a begonia so far as firmness goes. But it is almost safe to say where sturdy short-pointed growth is the natural habit of a plant when at its best, then it is a sure indication that firm potting is an absolute necessity. Never use a compost if it is too wet or too dry; to be just right it should merely hold together after being clenched in the hand. Over-potting above everything should be avoided, for this is the cause of more unhealthy plants than is generally realised. It is seldom necessary to use pots above two or three sizes larger than the one previously used. The aim should be to obtain a pot full of roots, and

then to feed the plants, and not to endanger the health of even the most vigorous growers by adding too much manure in any form to the compost when potting. Watering a newly potted plant should be done with caution; give one thorough soaking, and no more till the pot rings clear when tapped with the knuckles. During hot weather never expose plants after their roots have been disturbed, to hot sunshine, for it unduly distresses them, and then it is that they are often killed with kindness, through a too free use of the watering-can. It is doubtful if there is anything connected with plant growing that calls for time and patience more than potting, for, unlike much of the other work that is daily necessary to produce healthy plants, successful potting does not, as we have just seen, allow of any slipshod methods or thoughtlessness. Patience alone makes a good potter—a fact all should remember.

POTTING SHED.

In the notes on *POTTING* no mention was made of the potting shed, for the reason that this important item can be better dealt with separately. No fixed rule can be laid down here as to the building, but generally speaking, the aim should be to erect it as near to the growing houses as possible, in order to facilitate working, and to prevent tender plants from getting chilled through having to be carried to and fro in the open. In drawing up the plans for a potting shed, there are a few things that it may be well to point out, as, if they are not in the plan, afterthought means more expense, even if they can be carried out then. Of course unsightliness, as far as possible, will be avoided in selecting the site, but should it have to be in a very exposed situation, then make preparations for having the walls covered with suitable climbers at the earliest opportunity. Allow plenty of working room inside, by having a good long bench down one side, and study the whole thing from a working point of view. Try to make everything as convenient as possible, for remember when this is done, one has gone a long way towards obtaining a speedy output. Potting plants, even in expert hands, takes up a lot of time, and the operator can only turn out a maximum day's work who has everything to his hand. Avoid having any steps at all if possible, for they are nothing but a nuisance and a time waster. In addition to side windows have a skylight immediately over the potting bench, as also artificial light in whatever way it is to be employed. Above all, have the doorway wide enough to admit the wheeling of a barrow or the carrying of a handbarrow, for nothing is more annoying than having to handle plants two or three times over for the sake of a narrow doorway. Some means of providing artificial heat will be necessary, not only for comfort in working, but in order that the soil may be a little aired during the cold spring months. If the shed is large enough, a corner might be reserved as an office, for there are countless things to be noted if one is to get the best out of our short seasons. Cupboards for the storing of seeds must not be forgotten, and shelves for pots and stakes more than pay for themselves. Let the bench be made strong, and capable of

holding a few barrowfuls of soil; the benefit of this is always noticed during spring, by having soil at hand in a fit state to use. The same applies to stocks of leaf-mould, and well-rotted manure, which can always be kept under the bench. Other necessities, such as sand, charcoal, lime rubble, and crushed bones, together with broken crocks, should always be kept close at hand, for it is the finding of these things after starting potting that spoils a good day's work. Tools for potting with are not difficult to obtain; a piece of round wood, wedge-shaped at one end, forms the rammer; it can be made in various sizes to suit all kinds of pots; an ordinary hand hammer completing the necessary tools, which last is used for breaking up drainage material. Where many pots have to be used, a machine for washing them may well be included in fitting out a potting shed, for pots above everything should always be well cleaned before being used again. With a shed erected throughout on common-sense lines, there should be no time lost in needless running about, but to prevent rubbish and unnecessary stuff getting in the way during the busy season, it should be made the rule that a good clean up is done every day, since only by such means can a potting shed be prevented from becoming the lumber place one so often sees.

F. T.

POULTRY MANURE.

Poultry dung or fowl manure is an exceedingly useful material for the garden if properly used, but otherwise is a dangerous material to handle, as owing to its concentrated nature it is quite capable of poisoning one's plants instead of encouraging them to make fresh growth.

Much unnecessary waste goes on in the collection of poultry manure; the common practice is to sweep out the poultry-houses and throw the dung into a heap in the open and to use it as opportunity occurs for gardening purposes. After such a heap has had heavy rain on it much of the goodness has been washed out, the remainder being insoluble material of little garden value.

Drying Poultry Dung.—By far the better way is to collect all the sweepings and spread them out in thin layers in boxes or trays to dry, putting them in hot sun outside, and protecting them from rain, or put them in gentle heat indoors. They will then lose the water they contain, but the sun heat will not, and the indoor heat should not, be sufficiently great to drive off any of the ammonia they contain. When all the sticky nature has disappeared and the material falls to a fine dry powder it may be stored, preferably in tins with tight-fitting lids or well-covered barrels.

Using Poultry Dung.—Most crops are benefited by an occasional dressing of solid, or dose of liquid poultry manure. It is essentially a spring or summer fertiliser, suitable more especially for crops where leaf growth is required. For dry use it can be scattered on the ground at the rate of 4–10 lb. per sq. rod, and well hoed in. For use as a liquid manure one peck to each 80 gallons of water will be enough, and the liquid must be kept off the leaves.

Some Similar Manures.—Below we give a few notes on some of the lesser known manures which are more or less similar to poultry manure:—

Duck Manure.—This is suitable for all soils, but no great supplies are available. It is not usually considered a very rich manure, and

may be applied at the rate of 15–25 lb. per sq. rod in the spring-time.

GOOSE DUNG. — This is very similar to the above, and may be used in exactly the same way.

GUINEA-FOWL MANURE.—This is almost indistinguishable from ordinary poultry manure, and thus the material can be used in the same way.

PARTRIDGE MANURE. — Where many partridges are bred for shooting the amount of manure produced may be quite appreciable. It is not as rich as DUCK MANURE which we have mentioned above, and may be used at the rate of about 30 lb. per sq. rod, if put on about a month prior to sowing or planting. It is suitable for all soils.

PEACOCK DUNG.—Few typically ornamental grounds would be complete without their strutting peacocks, and where there are several birds, the manure collected may, if saved up, become appreciable in amount. Up to the present it has been used for garden purposes to a very limited extent, but may be applied to vacant land a short time prior to planting in much the same way as poultry manure.

PIGEON DUNG.—Sweepings from pigeon-cotes are very similar in appearance to sweepings from poultry-houses. If many birds are kept the amount of manure will be appreciable, and it should be dried and used in an exactly similar manner to poultry manure.

SEAGULL MANURE.—Those gardeners who live at the coast where there are extensive cliffs may be able to get some of this manure, but consequent on its exposure to the elements it is comparatively poor, and up to 35 lb. of it may be safely dug in per sq. rod of ground in the early spring, or indeed even in the winter. Very little is available, as a rule, and where poultry manure is available this is not worth the trouble of getting.

TURKEY DUNG.—The manure produced by turkeys, especially when they are being fattened up for Christmas, is rich, and useful for garden purposes if applied in dry form at the rate of about 6 lb. per sq. rod in the spring before planting.

PRATIA (Nat. Ord. Campanulaceæ).—This is a useful little genus of dwarf-growing plants which can be used for the front of borders or on rockwork in warm spots outside, but are more suitable for rock garden culture indoors. They require a compost of peat, sand, and good loam, one part of each, and may be propagated in the usual way by seeds in the summer or root division in the spring. *Pratia angulata* is the hardiest species, but *P. begonifolia* and *P. macrodon* are also worth growing. The first and last species bear white flowers, the second blue, and the flowering period of all extends from May to September. The height averages 1–3 ins.

PRIMROSE. — See *PRIMULA* and *WATER GARDEN: PLANTS FOR THE.*

PRIMULA (PRIMROSE. Nat. Ord. Primulaceæ).—The genus Primula is of high value to the gardener, and comprises many plants of great beauty and variety. A large proportion are hardy, and many of those of a tender character are charming in the greenhouse and conservatory. Their ranks have been largely reinforced within recent years by numerous introductions from China and other parts of the world, but the old favourites still retain their hold upon the affections of the flower-lover. The introduction of new species has afforded a wide field for the seedling raiser and hybridiser, and a considerable number of hybrids and varieties have been the result of his work. Within the scope of this publication it is impossible to give details of all the plants comprised in the genus. Many of them are, however, of little more than botanical interest, and others present great difficulties in keeping or cultivating them, so that those enumerated are only some of those which are readily amenable to cultivation, or possess special importance in other directions.

Culture.—In such an extensive genus, including plants from many parts of the world and growing naturally under the most diverse conditions, it is impracticable to give full details regarding every point, but it is convenient to divide them into several sections and to indicate the general requirements of each.

INDOORS.—The CHINESE PRIMULA, *P. sinensis,* has long been a favourite for greenhouse and conservatory cultivation, but the favour shown to *P. kewensis, P. malacoides, P. obconica, P. Sieboldi,* and others, has tended to reduce its popularity. It is, however, of high value, and, with the addition of representatives of the others, cannot be dispensed with for decorative purposes. In addition to these, some of the newer Chinese and Himalayan species are only satisfactory if cultivated under glass.

Seeds of these greenhouse Primulas should be sown in a gentle hotbed, or in pots or pans in slight heat, from March to June, in a soil composed of about two parts of leaf-soil, one part of loam, and one of silver sand. Put this through a sieve with a half-inch mesh, using the rougher material for the bottom of the pots above the drainage.

The pots or pans must be well drained, and filled with the soil to about half an inch of the top. Sow the seeds very thinly, and just cover with fine soil. Water carefully, and cover the pots with a sheet of glass and a piece of paper to exclude the light. Examine daily to see that the soil is sufficiently moist. As soon as the seedlings begin to appear remove the glass and paper, and expose gradually to air and light. Keep the seedlings near the light, but shaded from the sun. Place the pots in a temperature of 50–60° F.; prick off the seedlings when they can be handled, and grow on in a slightly lower temperature. This treatment suits the varieties of *P. malacoides*, *P. kewensis*, *P. sinensis*, and others, but *P. Sieboldi* may be given a slightly lower temperature.

Almost all the hardy Primulas make excellent pot plants, but they should be grown in a cooler house, and should receive plenty of air at all times. For their happiness a low house where they can be kept near the light, with ample ventilation, is best. They generally do well in a structure from which frost is just excluded.

With Primulas grown in pots under glass, green fly and thrips are troublesome. Gentle fumigation and other treatment referred to under the proper headings should be attended to whenever these pests are observed.

Outdoors.—A considerable number of the species grow well in the flower border, and a large proportion, especially those which prefer moist places, are capital plants for the wild garden and the margin of streams and ponds. In the list of species the best for this last purpose are indicated. In all cases a free, well-drained soil is preferred, and even many of the moisture-lovers are resentful of stagnant moisture at their roots.

Few of them prefer dense shade, and where their requirements in the way of water can be supplied, they like full sun in most cases. These hardy species can be raised from seeds sown under glass and given practically the same treatment as that suggested for the greenhouse. The temperature for the seedlings should, however, be rather lower, and care must be taken that they do not become too drawn for want of air or light. In addition to propagation by seeds, division is suitable for many species. Few of these should remain more than two or three years without being divided when they have made suitable offsets. It is desirable to note that a proportion of these plants die down to an almost invisible crown in winter, and that great care must be exercised in working among them when they are at rest. In all cases they should be clearly marked with a peg or tally.

Rock Garden Culture.—Hardy Primulas are indispensable in all good rock gardens. The European species are, as a rule, the best for rockwork, but for moist corners and at the base a considerable number of the others may be employed.

Some of them prefer to be grown in crevices of the rocks or, if on the level, jammed between two stones. Others are natives of pastures, and need to be cultivated on the level. In the absence of their natural carpet of greenery a mulch of grit and gravel of about half an inch thick will be highly beneficial. A number of these rock garden Primulas gradually rise out of the ground as the rootstock lengthens, and it is necessary to raise the soil about them to the level of the lower

leaves or to lift them and replant them deeper, so that the lower leaves just touch the soil.

KEY TO THE SELECTIONS.—In the selected list below those marked *B.* are suitable for the Border; *G.* for Greenhouse or frame culture; *H.H.* are nearly hardy; *M.* require moisture; and *R.* grow well on Rockwork.

SELECTION OF SORTS.

Primula acaulis (PRIMROSE).—Syn. *P. vulgaris*, which see.

P. admontensis (*R.*)—Lilac flowers in May. Height, 3–8 ins.

P. algida (*M.R.*).—Purple flowers in April. Height, 6 ins.

P. Allionii (*R.*).—Red-purple flowers in April. Height, 4–6 ins.

P. altaica (*B.R.*).—ALTAI PRIMROSE, with mauve flowers in March. Height, 3–6 ins.

P. angustidens (*B.R.*).—Purple-lilac flowers in May. Height, 6 ins.

P. Arctotis (*R.*).—White or lilac flowers in May. Height, 6 ins.

P. Auricula.—See article on *AURICULA*.

P. auriculata (*B.R.*).—Purple flowers in May. Height, 12 ins.

P. beesiana (*B.M.R.*).—Purple flowers in May. Height, 12 ins. *P. b. hybrida* is available in various colours.

P. biflora (*R.*).—Rose flowers in May. Height, 12 ins.

P. bullata (*R.*).—Yellow flowers in April. Height, 12 ins.

P. bulleyana (*B.M.R.*).—BULLEY'S PRIMROSE, with yellow flowers in April. Height, 12–18 ins.

P. bulleyana hybrida (*B.M.R.*).—Various colours in April. Height, 18 ins.

P. calycina (Syn. *P. glaucescens*) (*R.*).—Purple flowers in May. Height, 3 ins.

P. capitata (*B.M.R.*).—Violet-blue flowers in April. Height, 6–12 ins.

P. carniolica (*M.R.*).—Lilac flowers in April. Height, 3–6 ins.

P. ciliata (*R.*).—Purple flowers in May. Height, 3–6 ins.

P. clusiana (*R.*).—Rose flowers in April. Height, 6–9 ins.

P. cockburniana (*B.G.M.R.*).—Scarlet flowers from May onwards. Height, 9 ins.

P. cockburniana hybrida (*B.G.*).—Various colours.

P. cortusoides (*B.G.R.*).—Rose flowers in May. Height, 9 ins.

P. denticulata (*B.G.M.R.*).—Various colours in March. Height, 9–12 ins.

P. denticulata cashmiriana (*B.G.M.R.*).—Various colours in March. Height, 9–12 ins.

P. elatior (*B.R.*).—Various colours in May. Height, 8–12 ins.

P. Facchinii (*R.*).—Rose-purple flowers in May. Height, 3–6 ins.

P. farinosa (*M.R.*).—BIRD'S-EYE PRIMROSE, with rose-purple flowers in May. Height, 6 ins.

P. floribunda (*G.*).—Yellow flowers from March onwards. Height, 4–8 ins.

P. Forbesii (*G.*).—Rose flowers from March onwards. Height, 6–12 ins.

P. formosa (*B.R.*).—Pale purple flowers from May onwards. Height, 6 ins.

P. Forrestii (*G.R.*).—Yellow flowers in May. Height, 12–18 ins.

P. frondosa (*M.R.*).—Purple flowers from May onwards. Height, 2–6 ins.

P. glutinosa (*B.R.*).—Purple-lilac flowers in May. Height, 4 ins.

P. helodoxa (*B.M.R.*).—Yellow flowers in June. Height, 12–40 ins.

P. helvetica (*B.R.*).—Pink flowers in May. Height, 6–9 ins.

P. hirsuta (*B.R.*).—Rose flowers in April. Height, 6 ins.

P. hirsuta nivea (*B.R.*).—White flowers in April. Height, 6 ins.

P. integrifolia (*B.R.*).—Rose flowers in May. Height, 3 ins.

P. involucrata (*M.R.*).—Creamy-

white flowers in April. Height, 6–12 ins.

P. japonica (*B.M.R.*).—JAPANESE PRIMROSE, with flowers of various colours from May onwards. Height, 12–24 ins.

P. Juliae (*B.M.R.*). — Violet flowers in April. Height, 2–6 ins.

P. Kerneri (*R.*).—Violet flowers in April. Height, 2–4 ins.

P. kewensis (*G.*).—Yellow flowers from April onwards. Height, 9–18 ins.

P. longiflora (*R.*).—Purple flowers in May. Height, 12–18 ins.

P. luteola (*R.*).—Yellow flowers in May. Height, 18–24 ins.

P. malacoides (*G.* or *H.H.*).—Pink flowers from spring onwards. Height, 12 ins.

P. marginata (*B.R.*). — Purple flowers in May. Height, 6 ins.

P. minima (*R.*).—Rose flowers in May. Height, 2 ins.

P. nessensis (*G.M.R.*). — Pink flowers from May onwards. Height, 6 ins.

P. nivalis of gardens.—See *P. hirsuta nivea.*

P. obconica (*G.*).—In various colours from spring onwards. Height, 12 ins.

P. officinalis (*B.*).—The COWSLIP, with various colours in April. Height, 12 ins.

P. Palinuri (*G.R.*).—Yellow flowers in May. Height, 6–10 ins.

P. Parryi (*B.*).—Purple flowers in May. Height, 6–18 ins.

P. pedemontana (*R.*). — Rose flowers in May. Height, 6 ins.

P. Poissoni (*G.M.*). — Purple flowers in May. Height, 15 ins.

P. pulverulenta (*B.M.R.*).—Red flowers in April. Height, 18–24 ins.

P. rosea (*B.M.R.*).—Rose flowers in March. Height, 6 ins.

P. saxatilis (*B.G.R.*). — Rose flowers in May. Height, 9 ins.

P. sibirica (*B.M.R.*).—Red flowers in May. Height, 6 ins.

P. Sieboldi (*B.G.R.*). — Red flowers in May. Height, 12 ins.

P. sikkimensis (*B.M.R.*).—Yellow flowers in May. Height, 18 ins.

P. sinensis (*G.*).—Various colours from spring onwards. Height, 12 ins.

P. spectabilis (*B.R.*).—Rose-purple flowers in July. Height, 4 ins.

P. Stuartii (*G.R.*).—Yellow flowers in May. Height, 9–18 ins.

P. Sturii (*R.*). — Rosy-purple flowers in April. Height, 3 ins.

P. suffrutescens (*R.*).—Rose-purple flowers in April. Height, 12 ins.

P. tyrolensis (*R.*).— Rose-lilac flowers in May. Height, 2 ins.

P. variabilis. — See article on *POLYANTHUS.*

P. Veitchii (*B.R.*).—Rose-purple flowers in April. Height, 12 ins.

P. venusta (*R.*).—Purple flowers in April. Height, 12 ins.

P. Venzoi (*R.*).—Pale-purple flowers in April. Height, 6 ins.

P. veris.—See *P. officinalis.*

P. verticillata (*G.*).—Yellow flowers from spring onwards. Height, 12 ins.

P. villosa (*R.*).—Lilac or rose flowers in May. Height, 6 ins.

P. vincaeflora (*R.*).—Purple flowers in May. Height, 12 ins.

P. viscosa (*R.*). — Red-violet flowers in May. Height, 2–7 ins.

P. vittata (*M.*). — Pink-purple flowers in May. Height, 12–24 ins.

P. vulgaris.—See PRIMROSE in article on *WATER GARDEN: PLANTS FOR THE.*

P. Wilsoni (*R.*).—Purple flowers in April. Height, 18–24 ins.

P. Winterii (*G.R.*). — Mauve flowers in May. Height, 9 ins.

S. A.

NEW SPECIES AND VARIETIES.[1]

Primula Adonis. — Rosy-mauve flowers in large trusses. Height, 5–6 ins.

[1] A selection of those which have received special recognition.—EDITOR.

P. Beesiana Hybrida.—Orange, salmon, crimson, and other coloured flowers, borne in whorls.

P. Bookham Gem.—Violet-purple flowers with a white eye, borne in large fragrant trusses.

P. conica.—Lavender-blue flowers, paler inside, and downy, drooping leaves, on plants 6–12 ins. high.

P. conspersa.—Rosy-purple flowers, in two or three tiers, and dark green leaves, on plants 12–18 ins. high.

P. Cooperi.—Violet-purple flowers produced in one to three tiers on mealy stems.

P. Crispii.—Large dark purple flowers.

P. Eureka.—Large rosy-carmine flowers.

P. Jewel.—Deep purple flowers with a yellow eye, on stalks 3 ins. high.

P. Ladybird.—Rosy-carmine flowers, in whorls.

P. malacoides alba plena.—Pearly-white double flowers. A very free-blooming sort.

P. m. King Albert.—Large bright rose flowers with four or five whorls on a stem.

P. m. Princess Patricia.—Large warm rose single flowers. A very floriferous sort, of dwarf habit.

P. m. The President.—Soft double lilac flowers produced in whorls.

P. nutans.—Deep blue, nodding, cup-shaped, fragrant flowers, with their tube and stem mealy, and erect leaves, on plants 10–16 ins. high.

P. Reinii.—Lilac flowers borne just above hairy foliage, having five brown spots round the eye.

P. sino-purpurea.—Royal purple fragrant flowers, in umbels, with a creamy-white eye, and robust mealy stems.

P. sinolisteri.—Large white non-tiered flowers.

P. Ville de Nancy.—Vivid rose flowers.

P. Wanda.—Large bright crimson-purple flowers with a yellow eye.

P. Zuleika Dobson.—Large purple flowers with a white eye, and short rosetted leaves, on plants 4–6 ins. high.—W. J. C.

PROPAGATION OF PLANTS.

While the majority of plants are readily increased from seed, this is by no means the quickest method of reproduction. Some seeds require just as much care in sowing as fern spores, more particularly the finer seeds such as those of Gloxinias and other gesneraceous plants, also Begonias, and many species of Orchids. These, and many others, must be sown practically on the surface of a very fine soil or other suitable medium; for example, some Orchids, *e.g.* Cattleyas, are sown on living sphagnum moss. Some seeds again, such as Cannas, are so hard that they require to be soaked in hot water for several days in order to soften the seed-coat. Other seeds, *e.g.* those of Nelumbium or Sacred Lily of the Nile, are so hard that the shell is usually filed in order to facilitate germination. The whole question of propagation from seeds is, however, dealt with in a separate article on *Seed Sowing*.

Cuttings.—The more usual method of propagation practised in gardens is that of inserting cuttings of the parent plant in a suitable rooting medium. Some cuttings do not strike or root so freely as others. Much depends upon the hardness of the wood, the medium in which they are inserted, and also the temperature of such medium, whether it be soil, sand, cocoanut fibre, or even water. The chief advantage of increase from cuttings is that a fully-developed plant is obtained in a much shorter time than when seeds are sown, while not only is the resultant plant often stronger, but its character is usually preserved. As would naturally be expected, there are a great many variable conditions which contribute towards success or failure. Cuttings taken from semi-aquatic plants such as watercress, throw out roots in abundance whenever placed in a moisture-laden soil; whereas cuttings of other plants, whether soft or hard-wooded, would soon perish under similar treatment. Cuttings of succulent cactaceous plants such as Cereus, Mamillaria, Opuntia, etc., root more readily when placed in dry sand and exposed to hot sunshine. The propagation by cuttings of many hard-wooded trees and shrubs is attended by numerous failures, while much of the success obtained is due to the experience of the propagator in knowing under what conditions to select the cuttings, not only as regards season, but also with regard to the ripeness and hardness of the wood. Cuttings of soft-wooded plants generally require a much higher temperature, combined with a closer atmosphere, than that to which the parent plant has been accustomed, as this atmosphere prevents excessive transpiration, while the higher temperature both of soil and atmosphere encourages root action.

Callus is a word often used in reference to the rooting of cuttings, and refers to an exudation of the sap which circulates actively between the wood and the bark in all dicotyledonous plants. This sap gradually hardens to the consistency of rubber under certain conditions, which formation is less prominent in the case of soft than of hard-wooded cuttings. The callus produced in woody cuttings often thickens and hardens to such an extent that young roots are prevented from penetrating it, with the result that it has to be notched with a knife, and the cuttings subjected to increased bottom-heat before an adequate number of roots are developed. Many leafy cuttings such as Zonal Pelargoniums, are lost each spring by "damping off," a condition which is even more pre-

valent in the case of such cuttings as are of necessity confined to close frames. Damping can usually be checked by paying careful attention to ventilation. It is found that those exotics composed of firm wood, and which are of active growth, take longer to produce roots, and therefore require liberal ventilation, while if increased heat is applied with the object of forcing root growth, such action will often prove fatal, growth in this case being suddenly arrested. While the cuttings of many tropical plants can only be induced to make roots when the pots containing them are plunged in a hotbed, or beds of fibre subjected to bottom-heat, the majority of cuttings do not require to be plunged, and hard-wooded cuttings, including those of coniferous plants, require no bottom-heat. Cuttings of Conifers are usually selected from the terminal shoots of the branches during early autumn, at which season the sap is less active, and therefore the growths are soft. They are generally inserted in shallow pans of sandy soil, and covered with bell-jars or hand-lights.

Cuttings of plants such as Callicarpa, Capsicum, Rivina, Solanum, and many others of similar character, are best inserted early so as to ensure them flowering during the summer, and ripening their fruits in autumn.

When putting in cuttings of variable character, or where, as in Geraniums (*i.e.* Zonal Pelargoniums), some of the wood is quite soft, and that from other plants firm and hard, the two kinds should be kept separate. The harder cuttings are not so liable to damp off, and the wood, being fairly mature, roots freely, while the softer wood is very apt to rot, especially if the cuttings are watered immediately after being placed in the soil. To lessen the risk of decay it is advisable to allow the soft, sappy cuttings to wither for a day or so before placing in the soil, or, if inserted immediately they are removed from the parent plant, and trimmed, no water should be given until the second or third day.

Leaf Cuttings.—Leaves, being composed of tissues similar to those of the stem, admit, in some instances, of being used as a means of increase. *Begonia Rex* forms an excellent illustration of how leaves may be utilised in this way, while there are many other plants such as Bertolonia, Echeverias, Peperomia, Streptocarpus, etc., which may be similarly reproduced from leaves. Fully matured leaves must be chosen, these being pegged down on a bed of cocoanut fibre, or loamy soil, and sufficient bottom-heat provided to encourage root action. The larger mid-ribs of the leaf are severed with a knife, and it is at these incisions that a callus is formed from which the roots are emitted, little plants finally making their appearance.

Various Cuttings.—Then, again, we come across many plants that may be freely propagated from cuttings or sections of the root, as is commonly practised in the case of Seakale, but there are many others, among which the apple, pear, quince, rose, and whitethorn may be mentioned.

Difference in treatment is mentioned in case the beginner or inexperienced imagine that all cuttings can be treated alike. Carnations are often difficult to root from cuttings or "pipings," and it is largely on this account that they are layered. To facilitate rooting a common practice is to cut the stem long-ways to half an inch in length, thereby exposing a large surface of tissue to the soil for root formation.

In propagation of bush fruits from

cuttings, such as currants, gooseberries, etc., which are rooted in the open ground during the autumn, it is always advisable to put them out soon enough, as if left too late in the year the soil becomes cold, in which case they are not likely to become established before the spring, or until such time as the soil gets warm again.

Almost any plant may be propagated by cuttings if properly treated, and those who are accustomed to the habits of plants can usually tell how best to set about this form of increase. Decorative greenhouse plants, *e.g.* the Bouvardia and Pelargonium, may also be propagated from root cuttings, but as stem cuttings give stronger plants the former method is not generally adopted.

General Hints on Cuttings.—In practice it is found that cuttings root much more freely when in contact with the sides of the pots, so instead of setting two or three in the centre of a large pot, insert several round the edge of a small one.

When inserting cuttings see that the pots or boxes are well supplied with drainage, for which purpose potsherds of various sizes are generally used, over which a layer of decayed turf is placed, before the finer soil is added. Finally, a layer of silver sand or well-washed road grit is placed on the surface. With a wooden dibber make a hole sufficiently large to allow the cutting to enter the soil without force, see that the base of the cutting rests on a firm bottom, and if a little grit or sand is dropped into the hole before the insertion of the cutting, this will often prevent the newly-cut surface from rotting, and very much hasten the formation of roots. This is a small detail, but, nevertheless, a very important one. If cuttings are placed so loosely in the soil that they can easily be pulled out, there is little likelihood of their taking root.

Layering is a method of propagation largely practised in the case of those plants which are difficult to root from cuttings, and is commonly adopted by nurserymen when raising such plants as carnations, clematis, laurels, rhododendrons, vines, and many others. There are many modifications of layering, known as ringing, tonguing, twisting, wiring, etc.

The very fact of a stem or branch coming into contact with a moist soil is often sufficient inducement to that particular part of the plant to emit roots. Usually, however, a slit is made half-way through the stem in an upward direction, and the cut surface kept apart by means of a small piece of stone or wooden peg to prevent the wound closing and healing, and to admit of a greater number of roots being formed.

When layering it is usually advisable to remove from the shoot those buds not required to form stems or branches, after which the layer is pegged firmly in position and covered with soil. Should the portion protruding from the soil be considerable, staking will be necessary, as, if the layered shoot is allowed to rock in the wind, root action will be impeded.

Ringing, or the removal of a circular band of bark, is often done as a means of arresting the downward flow of sap, with the result that a callus is formed and roots put forth as in the case of cuttings. Ringing is preferable to twisting or wiring the stem. The twisting of branches or stems of many trees and shrubs previous to layering greatly facilitates rooting, but the practice is not a wholly desirable one, as the twisting damages the tissues

to such an extent that the plants may become cankered. It is evident that plants possessed of either hard, or extremely soft and brittle stems, cannot be treated in this way, and in their case wiring, or what is sometimes called strangulation, is often resorted to, as in the case of those hard-wooded plants which are difficult to propagate from cuttings or by layering. A piece of wire drawn tightly around the stem checks the downward flow of sap. The large amount of woody tissue which collects in consequence very soon emits roots, provided that the thickened band is pierced here and there with a skewer. If exposed to a dry atmosphere and kept surrounded by a pad of damp sphagnum moss, or embedded in soil by splitting a small flower-pot in halves and rejoining these around the stem, roots soon form. This is often practised in the rooting of the tops of Aralias, Dracænas, *Ficus elastica*, and plants which make a similar growth. In all such modifications of rooting the physiological conditions remain identical.

Procumbent, or climbing plants, such as *Hoya carnosa*, Ipomoea, Lapagerias, and endless others, are restricted to a serpentine method of layering, the stem being made to dip down at intervals into the soil, each lower curve being tongued and held in position by means of a wooden or wire peg. Roots are freely given out at the joints or nodes, and each section, after being severed, with roots attached, then constitutes a new plant.

Those readers who have visited or worked in fruit nurseries will have seen large numbers of currants, gooseberries, quince, and other plants retained as a means of providing stocks for grafting, made to produce a large number of rooted cuttings by having their shoots or seems notched near the base. If the centre of the bushes are then filled up with soil throughout the late autumn and winter, the majority of the semi-detached shoots will take root. This method is generally referred to as *mound-layering*.

Nature provides many illustrations of propagation other than that of scattering the seeds over the soil. It will have been observed that many plants throw out suckers from the base of the parent plant, as in the case of raspberries and other species of Rubus. Plums and many other stone fruits will also develop suckers in profusion, which last may be removed and transplanted as stocks upon which to graft other varieties. This, however, is not always a wise plan, as plants so raised are apt to produce suckers later in life much more freely than stocks raised from seedlings.

Grafting.—Scientific research has brought much to the notice of the practical cultivator, and by a careful study of plant life, ways and means of propagation have been suggested which at one time would have been considered impossible. Grafting and budding are perhaps the most important methods of increase. The chief advantages claimed by these methods are to economise time, as for example, in the case of many fruits the grower would have to wait some years before the trees arrived at a profitable age, whereas when grafted on dwarfing and more fibrous rooting stocks the excessive vitality of the plant is checked, with the result that fruit buds are readily formed. Thus the whole habit of growth of the plant becomes altered, a condition which is well demonstrated where apples are grafted on the

Paradise Stock, or pears on the Quince Stock. Again, if we take the case of roses, these, if growing on the wild briar or Dog-rose, make a vigorous growth, and are not well adapted to the lighter and shallower soils, but when grafted or budded on the French briar of less robust root action, plants suited to these shallower and lighter soils are secured. Like apples on the Paradise Stock and pears on the Quince Stock, roses have not the longevity when placed on the Manetti or less robust rooting stocks; in each case fertility and fruit production is obtained much earlier. Budding and grafting admits of many plants being increased in very large numbers and in a short space of time, when it would be difficult to root from cuttings or propagate in any other way.

By either budding or grafting we are able to grow certain plants on soils and in climates which, under ordinary circumstances, would be quite unsuited to their growth. As an example of this it is found that peaches succeed very well in heavy, tenacious soils when grafted on certain varieties of Plum Stocks. So great is the variation in some cases, that we have known pears intended to be grown on light soils to be grafted on the Mountain Ash, but these are exceptional cases which need not be enumerated as they are so seldom practised. As a rule, plants having similar physiological characteristics unite freely, mere relation with regard to genera or species often serving as little guide to the propagator. Often, while no difficulty may be presented in securing a union, the results so produced are anything but satisfactory from a commercial point of view, and prove a disfigurement to the tree. It may be noticed in peaches that very often the stem of the scion or graft is altogether out of proportion to that of the stock. There are many forms of grafting, each depending upon the difference of diameter between the scion and the stock; but in every case it is necessary to bring the cambium layer of the scion in contact with that of the stock.

To ensure success the stock should be reasonably dormant, or just about to be active, when the scion is inserted, and to obtain this condition it often becomes necessary to retard the growth of the stock by heading it back early in the year before the sap begins to flow. Care must also be taken in seeing that the grafts are not too forward or in excess of the growth of the stock. Some pears burst into bud very early in the season, and therefore it becomes necessary to place in a cool situation and completely cover them with soil until such time as required for grafting. When the graft has been placed in position it is necessary to keep it there by tying securely with grafting wax, of which there are many preparations made of pitch, resin, beeswax, and turpentine, although some nurserymen still use a mixture of very plastic clay, with which is incorporated some well-spent cow-manure to prevent the clay from cracking. The object of the covering is to guard against the drying effects of air and sunshine.

Of the different modes of grafting, that known as WHIP- or TONGUE-GRAFTING is most generally employed in treating with hardy fruits. Needless to say when the stock and scion are of equal diameter a perfect union takes place, but where the scion is of smaller diameter as compared with that of the stock, it is necessary to ensure that at least one side of the cambium layer of the scion coincides with that of the stock, otherwise no

union will be effected. The advantage of the tongue to the scion is that when placed in a corresponding cleft in the stock the two are kept in position.

NOTCH-GRAFTING is resorted to when the diameter of the stock is three to five times greater than that of the scion; a notch-like incision is made in the stock, while the scion is shaped after the manner of the piece removed from the stock, on to which it is then fitted.

CROWN-GRAFTING is adopted in the case of very large trees, as it not unusually happens that after ten years' or so growth, some varieties of orchard trees are found to be unfruitful in the district in which they are growing, and rather than sacrifice the whole tree, it is much simpler to cut back the leading branches and insert grafts in each branch. To perform this successfully the bark is merely cut to the length of an inch or so, and slightly raised to admit of the graft being pushed home between the bark and the wood. The graft only requires to be cut in a sloping direction, as practically the whole of the cut surface is exposed to the sap rising in the larger branches. In the case of one failing, two scions are usually inserted, the wound being well covered with wax. There are many other methods of grafting, such as splice-grafting, side-grafting, saddle-grafting, etc.

INARCHING is a term applied to a form of grafting wherein the scion is only partly severed from the parent plant, and is therefore dependent upon it until such time as a union is effected. In gardens and nurseries very many plants are increased by grafting. All the variegated ivies are grafted on the commoner species, and similarly the more delicate and tender varieties of Clematis are grafted on the roots of the stronger species, namely, *Clematis Vitalba*, or Traveller's Joy, of the woods, which possesses a very robust constitution coupled with strong root action.

Budding, or to be more correct bud-grafting, is only another modification of grafting. The chief distinction is that a dormant bud, with a small piece of wood or bark attached, is transferred to the stock when the latter is in a more advanced stage of growth, the operation usually being accomplished throughout the months of July and August. The operation, when applied to the many varieties of stone fruits, calls for some dexterity before efficiency is attained. As in all cases of grafting a very sharp knife is essential, for if the delicate rind of the bark is bruised this may cause failure.

If we take as an example the budding of a briar, we will assume that the briar has been planted in November; in the spring a few buds break from near the extremity of the plant, three of which are selected or allowed to continue their growth. Just previously to being budded these are shortened back to within a foot or so of the main stem; the reason for doing so being to prevent the elaboration of the sap at the ends of the branches or growing points. Dormant buds are removed from the variety of rose it is intended to increase, and transferred to the stock. For the reception of the bud a T-like incision is made on the shortened-back branch, on the underside for preference, the closer to the stem the better. A portion of wood will be attached to the bud which was removed, and this is better disposed of by jerking it out with the point of the budding knife, but if it does not come away freely it had better not be unduly forced. Holding the bud by the stem of the leaf,

raise the bark at the incision, as this will admit of the point of the bud entering without undue pressure. It can then be gently pressed into position. Now bind the bud in position with raffia, but apply no grafting wax. As with all similar operations, a little practice is needed before efficiency is attained.

Having inserted a bud on each branch, nothing now remains but to allow the briar to make what growth it chooses. The buds, if they take properly, will remain dormant throughout the summer and winter, and will be well nourished. In the following spring they will show signs of starting into growth, and to facilitate this cut back the length of briar above the bud; this will have the effect of stimulating the bud, due to a larger supply of sap. During the summer the head of the briar is composed of the growth resulting from these buds, which becomes well matured, flowers, and is pruned back in the ordinary way at the winter pruning. As with grafting, there are several different methods of budding practised, such as flute- and shield-budding, but after all the principle is the same throughout.

We must mention the advisability of shading the buds after insertion during excessively hot weather, and this may be done by placing a cabbage or rhubarb leaf on or around the stem on which the bud has been placed. Grafts or scions are often placed on the root, which operation is known as ROOT-GRAFTING, but buds are rarely ever placed so low down.

Division of the Roots.—Another means of propagation not yet mentioned is by means of division of the rootstock. This is very simple, inasmuch as it only consists in dividing up the plant by means of a spade, a sharp knife, or by pulling the various fibrous-rooted plants asunder. Flowers of the herbaceous border are largely increased in this manner.

Various Methods. — Clumps of Rhubarb in time become very large and exhausted, therefore they have to be divided, and the sets or offshoots planted in newly prepared and manured soil. Bulbs and tubers require quite another treatment. All true bulbs may be propagated by scooping out the base of the central bulb, or in such a way as to cause it to develop lateral buds or bulbils at the base of the scales. Bulbs of lilies, such as *Lilium auratum*, may be increased by removing the matured scales and pricking them out into boxes of sandy soil. Many bulbs—such as Crinums, Narcissi, and Tulips—divide or develop offsets from the base, and in this way present a ready means of propagation. Corms, as in the Crocus, multiply readily from buds which grow into corms and supplant the older ones. Caladiums and many other varieties of Aroids are propagated from eyes which are developed over the upper side of the corm.

A study of the plant will usually present many suggestions for propagating or increasing it. For example, in the Strawberry, where runners are developed in abundance from the parent plant, or again, on those plants like the Iris and many ferns of the Davallia type which increase by rhizomes. Where portions of a plant are removed without roots, they are all the better for being shaded and the atmosphere kept moist, as it is useless to water the pots containing the cuttings and sections of the plant until the roots appear. In the same way when increasing tuberous-rooted Begonias, it is very preferable to start the cut tubers by laying them on a bed of moistened cocoanut fibre until the roots show signs of development. The development of roots may readily be

noticed where potato tubers are placed in trays to sprout. There is usually enough moisture and food in the tuber to provide all that is necessary for growth up to a certain stage. A careful observer and student of nature will usually become an efficient propagator of plants, as he will carefully study the habits of each plant that comes under his observation.—J. C. N.

PROTECTING PLANTS: MODES OF. Many of our favourite perennials, such as Delphinium, Galega, Geum, Pyrethrum, etc., are liable to suffer from the frost if in exposed positions. There are several modes of protecting these plants, some of which are mentioned below.

There is no doubt to my mind that the best way, if such is practicable, is to fork up the more tender perennials, and plant them in October in coke-dust ground moderately fine, in an old frame. The plants are packed rather close together, and labels put in at the bottom of such rows as are formed. Then in cold weather an old light or two may be thrown over the frame, or even mats without the lights, and such protection will be found quite sufficient under ordinary circumstances to prevent damage.

It is very provoking to lose a number of one's plants during frost; but some will say that the method just described is not worth the trouble, and indeed it is often inconvenient to disturb the plants. But their positions may be roughly gauged by placing sticks where the plants were forked up, and a method such as this enables those parts of the border to be properly dug over and manured.

Another method which finds great favour with some, is to cover the roots and crowns with material of one kind or another. This material may be cinder-ash, leaf-mould, strawy-manure, or even pieces of matting. I do not advise the use of manure, since the liquid made by the rain soaking through is most likely to corrode the roots. Pieces of matting may be used if desired, but I would rather use leaf-mould or cinder-ash. Straw might be used if made compact and firm.

If leaf-mould or cinder-ash be used, build up a mound over the crown, and let the crown be covered several inches deep. Arrange the material with sloping sides so that the rain will run off, and make it fairly firm. Do not do this so long as the weather keeps open and moderately dry, and so long as there are no sharp frosts. Rake off the material in early March, for the plants will be starting to grow. The leaf-mould may then be forked in, but the cinder-ash had better be collected and removed as it will do no good.

Such plants as the *Chrysanthemum maximum,* Doronicum, Erigeron, and perennial Sunflowers need not have this care bestowed upon them. It would be sheer waste of labour, since such strong kinds of plants are quite able to take care of themselves in any average winter.—E.

PROVENCE ROSE (*Rosa gallica provincialis*).—See *ROSE SPECIES*. For the best varieties see *ROSE CLASSES*.

PRUNELLA (SELF-HEAL. Nat. Ord. Labiatæ).—This is a small genus of dwarf plants suitable for the rock garden or rock border, or for edgings to the perennial border, the medicinal value of which has fallen into disrepute. They are of very easy culture, and may be propagated by dividing the roots in the usual way in the spring. *P. grandiflora*, and its variety *rubra*, are the sorts most often grown. They bear blue and red flowers in July and August. *P. laciniata* (Syn. *P. alba*) is the best white species. *P. vulgaris*, and its varieties *laciniata* and *rubra*, all known as the COMMON SELF-HEAL, are hardly worth growing. The height of all the species rarely exceeds 6 ins.

See also *MEDICINAL HERBS*.

PRUNIER DE ST. JULIEN (*Prunus communis juliana*).—See *TREES*.

PRUNING CLIMBERS.—See *CLIMBING AND TRAILING PLANTS*.

PRUNING FRUIT TREES.

The method of pruning fruit trees must be governed or determined by the form the tree is intended to assume, and by the nature of the tree itself according to habit and inherent peculiarities. Apples, Pears, Plums, and Sweet Cherries fruit on spurs, and may be pruned accordingly; but a few Apples produce the best fruits at the end of shoots, and these should be preserved till the fruits are gathered at least. Apricots, Morello Cherries, Nectarines, and Peaches fruit all along the length of the previous year's shoots, and these must be left full length, regulating the pruning by thinning out the old shoots, and by disbudding in early summer.

Standard Trees.—These should be pruned in the early stages of growth to get eight to twelve leading branches to form the head of the tree. The first year only three shoots at regular distances apart should be allowed. At the winter pruning cut these back to 12 ins. Several shoots will arise from them the following summer, but all except the two best placed on the primary shoots should be stopped at an early stage of growth. If these six are shortened to 12 ins. again in winter, two more from each should be allowed to grow, and this will give twelve leading branches, which will be enough to form the head of the tree. After this, standards and half-standards should be allowed to grow naturally, merely regulating the head by thinning out shoots where crowded and cutting away all dead wood. Always prune just above a bud pointing in the direction the shoot is desired to grow.

Pyramid Trees.—These are best suited for Apples and Pears, and the essential feature of them is that they should have a central, upright stem or trunk. The branches should be longest at the base of the tree, and gradually become shorter towards the top of the tree. When newly planted, the necessary pruning should be given to keep the tree in form and every year afterwards. First remove the shoots that cause crowding, then shorten back all growths one-third of their length. Some may require a greater length to be removed and others less, to maintain the shape of the tree, and this must be done with discretion.

Bushes.—If a start is made with a maiden tree, cut back the main stem to 12 ins. from the ground. In the second year aim at getting a bush open in the centre, with all branches regularly disposed. Thin out those that cross one another, and shorten the remainder one-third of their length, cutting above a bud in each case pointing in the direction that succeeding growth should take, to form a bush with branches extending in every direction, at equal distances apart. Apples, Plums, and Sweet Cherries are suitable for this form of tree.

Espaliers.—The branches of trees in this form of training must be fastened up horizontally to wires trained between two stout end posts, or to wooden spars fixed horizontally on upright posts, 6–8 ft. apart. Trees already partly trained can always be procured from the nurseries, but maiden trees can be planted and trained by the grower. Cut back the maiden tree to 9 ins. from the ground, so that the first pair of side branches will have a rise of 3 ins. before being tied down horizontally to the wires or other supports. During the following winter prune back the leader to 12 ins. and shorten the side branches one-third their length if strong, or to one-half if weak. In succeeding winters cut back the side-shoots of the branches to 1 in. and shorten the leader and all side branches as before, and so on till the espalier is covered.

Wall or Fence Trees.—Apples, Apricots, Morello Cherries, Nectarines, Peaches, Plums, and Sweet Cherries all succeed best when trained in the fan shape. Pears should be trained horizontally, or as oblique cordons, at an angle of 45° on walls or wooden fences. The leaders of Apples, Pears, Plums, and Sweet Cherries should be shortened to 12 ins. every winter, to provide for successive pairs of side branches and a new leader. All side-shoots should be shortened to 1 in. to form spurs. If summer pruning is adopted, shorten all side-shoots to four or five leaves, between the end of July and the end of August, but further shorten them in winter to two or three buds. The winter pruning may be done from the time the leaves fall till the end of February, but not in frosty weather.

Apricots, Morello Cherries, Nectarines, and Peaches always produce far more shoots than can be laid in at 4 ins. apart, and should be disbudded when the young shoots are only 1–2 ins. long. Leave two young shoots at the base of the fruiting ones, and one at the apex. This is generally sufficient to furnish enough fruiting wood for the following year, but discretion or judgment should be exercised in case old branches have to be covered with young shoots. After the fruit is gathered, some or all of the fruiting shoots may be cut out, and the trees otherwise regulated to prevent crowding. This, of course, could be done in winter, preferably not later than the beginning of February, as the buds are then far advanced.

Cordons.—These are suitable for training on walls, fences, or espaliers. The oblique cordon, trained at an angle of 45°, is the best for Apples and Pears, and for Plums to a less extent. They may be single double, or treble. The best form of pruning for this form is to shorten back all side-shoots to four or five leaves, from the end of July to the end of August, and further shorten them to two or three buds in winter. The leader should never be shortened till the limits of space are reached. By this method of oblique training a greater length of stem is obtained

than by training the trees upright; the trees also fruit better, because growth is more restrained. As the trees grow older they may be lowered and still longer stems obtained. Apples may also be grown as horizontal cordons tied to wires, stretched between posts, and 12 ins. from the ground, alongside of garden paths. The cordons may be single and trained all in one direction, or of two branches, trained right and left. The pruning is the same as for oblique cordons.—J. F.

PRUNING OF BUSHES.—See *PRUNING FRUIT TREES.*

PRUNING ROSES AND SHRUBS.

Roses are pruned, first to encourage stronger growth in the case of weak growers, and to weaken it in the case of strong growers; secondly, in order that the flowers may be larger and of better quality; thirdly, to admit light and air to strengthen and ripen the wood; fourthly, to make the foliage healthy and vigorous; and fifthly, to keep the plants within due bounds. Speaking in a general way, in the case of bush roses, the weakest-growing Hybrid Perpetuals and Hybrid Teas are pruned hardest, in order to make them produce stronger shoots during the following summer, and the strongest growers must have the best shoots cut in such a way that the next growths will be weaker. If strong growers were pruned hard they would grow stronger during the coming summer and flower badly or not at all. Those of intermediate vigour must be pruned in a medium way, cutting away neither too much nor too little, but just an amount calculated to give the requisite strength in the new growths. Bearing these things in mind the pruner must learn to use his own discretion to secure the best results. The instructions here given are to enable the beginner to prune Roses to get plenty of flowers for cutting and for garden decoration. To get fine blooms for exhibition, the pruning must in all cases be harder or more severe.

In pruning a bush rose the operator should begin by cutting out dead wood and snags, as well as all the weaker shoots that tend to crowd the centre. The remainder will be strong shoots from the base or near it, and laterals from older wood. Shoots from the base are mostly the strongest, and give rise to the best blooms. A simple way of dealing with these is to cut back 4–6 ft. shoots to 2–3 ft., or peg them down; shoots 2½–3 ft. in length to 12–18 ins.; shoots 1½ ft. in length to 8 ins., or 12 ins. if strong; and all weaker ones to 4 ins. or 6 ins. The laterals should always be pruned hard, say 2–4 ins., unless very strong. Another simple rule is to cut away one-third the length of the tallest growers; one-half the medium growers; and two-thirds of the weak growers. Examples of those that require only one-third of their length cut away are *Caroline Testout, Florence Pemberton, George Dickson, Gustav Grunerwald, La France, La Tosca, Louise C. Breslau, Rayon d'Or*, and *Ulrich Brunner*. A few bloom best when cut down to three or four eyes, such as *Coronation, Lady Faire, Lady Hillingdon, Liberty, Mrs J. Laing, Mrs R. G. Sharman-Crawford, Mrs W. J. Grant, Prince Camille de Rohan, Richmond*, and *Victor Hugo*. Roses that do best pegged down are *Frau K. Druschki, Gruss an Teplitz, Hugh Dickson, J. B. Clark, Juliet, Madame Isaac Pereire*, and *Madame Jules Gravereaux*.

Climbing Teas and Noisettes, and Climbing Hybrid Perpetuals

should be allowed to grow much as they like, merely cutting out stems that are more than two years old when too crowded for the situation. Laterals may be thinned and the strongest ones shortened to prevent overcrowding.

Climbing Polyanthas may have the old and weak shoots cut away in August or September, as soon as they have done flowering, to let the strong young wood ripen. Examples are *American Pillar, Crimson Rambler, Electra, Goldfinch, Tausendschon, Trier,* and *Veilchenblau.*

Wichuraiana Roses, such as *Dorothy Perkins, Elisa Robichon, Excelsa, Hiawatha, Lady Gay, Leontine Gervais,* and *White Dorothy,* may be pruned much the same as Climbing Polyanthas, and at the same time, but in neither case need the stems that have flowered be cut away if wanted to cover a trellis, etc. Many shoots of the Wichuraiana Roses produce strong laterals without flowers, that will bloom the following year. It will be noted that all Climbing Roses bloom on short shoots from the wood of the previous year, so that strong young shoots should never be cut away.

China Roses require very little pruning. Long, straggling shoots may be shortened; then cut back the old flower stems to a good bud, and thin out the centre if crowded.

Japanese Roses (*Rosa rugosa*) and their hybrids flower on short shoots from the long stems of the previous year; hence these long stems should only be tipped or slightly shortened. Old stems may be cut out when crowded.

WHEN TO PRUNE.—Hybrid Perpetuals and Hybrid Teas should be pruned about the middle of March, in the south of England; during the third week in the Midlands; and during the fourth week in the far north. Tea Roses should be pruned about the end of March in the south; at the beginning of April in the Midlands, and about the second week of April farther to the north.

Shrubs.—Pruning in this case is only necessary to keep the bushes in shape, to reduce them to reasonable or moderate height, to prevent overcrowding of the branches, and to prevent one bush from growing into another and spoiling it. In carrying out the operation, in the case of flowering bushes, regard must be had to the time of flowering. Those that set their flower buds in the previous autumn, and bloom in spring or early summer, must be pruned immediately after flowering. The Forsythias, Flowering Currants (*Ribes*), *Prunus triloba, Spiraea arguta, S. Thunbergi, S. prunifolia,* and *S. canescens* may be pruned in April, earlier or later when flowering is finished. Shorten back the flowering shoots and trim the bushes into shape. Lilacs should have all suckers removed with the spade in winter, and be well cut back in June, if too tall, the weak shoots being cut out, if crowded. Guelder Roses and Snowball Trees (*Viburnum Opulus*), Mock Oranges (*Philadelphus*), Deutzias, and Weigelas should have their flowering shoots cut back after they have finished flowering, or be well cut back, if too tall, leaving the lower or short stems unpruned. Ornamental Cherries, Flowering Crabs, and Almonds should be pruned as little as possible, but if too tall or wide, trim them back after flowering. Cut the flowering shoots of *Hydrangea hortensis* well back after they fade, but leave the flowerless ones untouched.

Shrubs that flower on the young wood made during the current summer, may be cut back any time from November to the beginning

of March. These include *Ceanothus azureus, C. Gloire de Versailles, C. Marie Simon,* etc.; also *Spiraea japonica, S. Anthony Waterer, S. salicifolia, S. ariaefolia,* and others of that class; also *Buddleia variabilis,* Colutea, *Hydrangea paniculata,* Honeysuckles, *Jasminum officinale,* etc.

Evergreen shrubs, such as *Berberis Darwinii, B. stenophylla, Buddleia globosa,* Choisya, Rhododendrons, etc., may have straggling shoots shortened, but all the rest left untouched.

In the case of wall climbers nail up all strong shoots necessary to cover the wall, and then shorten back side shoots to 2–3 ins. Chimonanthus, *Jasminum nudiflorum,* etc., should not be pruned till they have done flowering, then do it immediately.

Tools to Use.—All shrubs and trees with broad evergreen leaves, whether grown as bushes or for hedges, should be trimmed with a knife or sécateurs (not the garden shears), to avoid disfiguring the leaves. Laurels, Hollies, and Aucubas are examples of this class.

PTEROLOBIUM.—Now included in the genus *Thlaspi.*

PTILOTRICHUM.—Now included in the genus *Alyssum.*

PTYCHOTIS.—Now included in the genus *Carum.*

PULEGIUM.—Now included in the genus *Mentha.*

PULICARIA (Nat. Ord. Compositæ).—Two species of this genus, *P. dysenterica* (Syn. *Inula dysenterica*) and *P. vulgaris* (Syn. *Inula Pulicaria*), known respectively as Flea-bane and Lesser Flea-bane, are sometimes grown, or offered for culture, in herbaceous borders. They are yellow-flowered plants blooming from June to August, and averaging 1–2 ft. in height. They cannot be said to be subjects of much value, though of very easy culture. Care should be taken not to confuse this genus with the more valuable *Erigerons* and *Inulas* (see separate articles), on account of the similarity of the English names.

See also under Erigeron in *Medicinal Herbs.*

PULMONARIA (Lungwort. Nat. Ord. Boraginaceæ).—Many of the species of this genus are now referred to the genus *Mertensia,* in the article on which we describe *Pulmonaria alpina* as *Mertensia alpina*;

P. maritima as *M. maritima*; *P. paniculata* as *M. paniculata*; *P. sibirica* as *M. sibirica*, and *P. virginica* as *M. pulmonarioides*. All the species are hardy herbaceous perennials useful for the front of mixed borders, shrub borders, and so on. They thrive well in ordinary light, rich soil in a sunny site, and are best propagated by division of the roots in March, when they may be most successfully planted, or by seeds sown at the usual time in the summer. We recommend the following, all of which are grown at Kew :—

Pulmonaria angustifolia.—This may be used, on account of its dwarfish habit, in the rock garden. It bears pretty violet flowers in April and May, on plants 9 ins. high. Its variety *azurea* bears delightful sky-blue flowers, and grows 12 ins. high.

P. arvernense.—This bears pretty purple-blue flowers from April to June, and grows 12 ins. high.

P. azurea.—This nursery sort is the variety *azurea* of *P. angustifolia* described above.

P. montana (Syn. *P. mollis*).—This bears attractive blue flowers from April to June, and grows 12 ins. high.

P. *officinalis* (COMMON LUNGWORT).—This may be considered the least attractive of all. It is found growing wild in many parts of England, and bears, as many readers will be aware, pink flowers in April and May, on plants 12 ins. high.

P. rubra.—This is a useful bright red sort blooming in May and June, and growing 12 ins. high.

P. saccharata.—This is a pretty pinkish species blooming in May and June, and growing 12 ins. high.

PUMPKIN (*Cucurbita maxima*).—See *CUCURBITA* and *PUMPKINS AND GOURDS.*

PUMPKINS AND GOURDS.

These may be grown and used in much the same way as *VEGETABLE MARROWS*, which see. Some sorts are attractive plants for growing up or alongside of fencing on allotments. For descriptions of the very numerous forms of edible Gourds and the several kinds of Pumpkins reference should be made to the catalogues of the bigger seed specialists. The best ornamental species are included in our article on *ORNAMENTAL GOURDS.*

PUNICA.—For the best species see *CLIMBING AND TRAILING PLANTS.*

PURGING FLAX.—See under FLAX in *MEDICINAL HERBS.*

PURITY TEST.—See *SEED TESTING.*

PURPLE-FLOWERING RASPBERRY (*Rubus odoratus*).—See *SHRUBS.*

PURPLE LABURNUM (*Laburnum Adami*).—See *TREES.*

PURPLE LOOSESTRIFE.—See *LYTHRUM.*

PURPLE OSIER (*Salix purpurea*).—See *TREES.*

PURPLE ROCK-CRESS.—See *AUBRIETIA* and *CRESS.*

PURPLE VETCH (*Vicia bithynica*).—See *VICIA.*

PURSLANE.—See *SALAD PLANTS.*

PURSLANE, ANNUAL (*Portulaca.* Nat. Ord. Portulaceæ).—The salading Purslane is described in our article on *SALAD PLANTS.* Some of the annual forms are, however, useful in the garden and require a sunny and rather dry position. In dull, wet seasons they are not a success. Seed should be sown in April, and the seedlings either thinned or transplanted to 6 ins. apart. The best species is :—

Portulaca grandiflora.—A purple and yellow June flowered annual, of which scarlet and white forms are also available. Height, 6 ins.

PYCNOPTERIS.—Now included in the genus NEPHRODIUM, for which see *FERNS AND FERN GARDENING.*

PYGMY CATCHFLY (*Silene Pumilio*).—See *SILENE: ROCK GARDEN SPECIES.*

PYRAMID FRUIT TREES.

To those about to plant Pyramid apples my advice is similar to that given by "Mr Punch" to those about to marry—"Don't."

This is not a revolutionary doctrine, and requires some explanation. In speaking of pyramids now is meant the true pyramid—a tree composed of one upright centre stem, the branches radiating outwards therefrom and one above the other.

If a symmetrical appearance only is aimed at, the pyramid is perhaps easier to keep neat, but if the best fruit in quantity be the main object, then the open, cup-shaped bush is infinitely preferable, and may also be an object of pleasing appearance.

There are two very serious and irremediable objections to the pyramid form for apples. First, one side is always in the shade; the branches on the sunny side necessarily shade those on the other. Secondly, sap naturally rises, and the branches at the top get a greater share than those below, the result being weakness and gradual suppression of the lower branches, unless great skill is exercised in maintaining the balance.

The true pyramidal form for pears and plums is not so objectionable as it is in the case of apples, since both these fruits mature fairly well in partial and intermittent shade; but apples require a maximum amount of sun to ripen and finish properly; also direct sunshine is necessary for the ripening of the wood and fruit-buds.

The open bush form is the better because every branch receives its full quota of sunshine, the rays reaching the branches on the north side between those on the south. It should be cup-shaped, the branches emanating from nearly one point in the stem about 1 ft. from the ground, and the stem should terminate at this height. A better simile is that of a very short-stemmed wine-glass. There is no fear then of one branch usurping all the share of the sap, as the sap flow is divided between eight or twelve main branches forming the sides of the glass.

Most gardeners know that sunshine is absolutely necessary to enable the leaves to perform their function of converting the crude sap into food for the tree, and, therefore, those leaves which get less than their share cannot nourish the fruit buds as they should. Fewer and weaker fruit buds mean fewer and weaker flowers and consequently less fruit; also apples grown in partial shade are never so well finished as are those grown in the full sun.

Granted, then, that the open bush form is the best, the method of pruning to form this shape is to cut down the one-year-old tree to about 1 ft. 6 ins. from the ground line. From this point will emanate two or three branches. These are cut back the next winter half-way, and then from this point two or three more grow. Select two in the best position for the formation of the side of the cup, and then there will be six main branches. Cut half the new wood away again the following winter; again select two branches, and the result is twelve main branches all forming the sides of the cup.

The amateur or private gardener usually buys a tree with the foundation already laid in the nursery, and the earlier operations have, in this case, been carried out.

As a rule twelve branches are sufficient, and when these have attained a height of 8 ft., the tree may be said to be fully grown. During the earlier years all side

shoots not required for extensions, should be cut back in late August or early September to about five or six leaves, in order to encourage the formation of fruit buds on the few inches of wood left, and eventually fruit spurs or collections of fruit buds. Once the tree has attained full size all side shoots may be cut back in late summer, leaving the extensions or leading shoots at the tops of the branches till winter, when they also should be removed. In after years the fruit spurs may be thinned to contain not more than two fruit buds next the main branch. Amateurs may recognise fruit buds by their larger size and, in the case of apples, generally downy scales, wood buds being very small in comparison.

The same method of pruning is adopted in the case of the pyramid, except that the centre stem is carried up straight, the young wood being cut back half-way in winter, to provide the branches which grow from the three or four wood buds immediately below the pruning point.

Similar procedure obtains in the case of bush and pyramid pears and plums, but side shoots of plum trees must not be so closely pruned at any time, since the bulk of the fruit is produced on young, weak twigs of the previous year's growth. The method of formation is the same in every case.

Sweet Cherries are managed on similar lines, but all pruning should be done in September before the leaves fall.

Cherries are impatient of the knife, and if pruned in winter signify their dislike by "gumming" and becoming unhealthy. When pruned in late summer the leaves can take up more of the sap, bleeding is avoided, and the leaves being still active, the cut is healed quicker and better than is the case in winter. The Morello Cherry is quite unlike the above in its habits; it fruits almost entirely on young wood made the previous summer. Therefore a large proportion of moderately strong side shoots must be left in to carry next year's crop, only cutting back in September some strong young shoots to keep up a succession of young growth, and removing as many as possible of those shoots that have just borne the crop.

There is no doubt whatever that the open bush is the finest form of all for *general* use. If grafted upon dwarfing stocks (as most apples and all pears should be), some fruit may be expected under ordinarily favourable conditions from a three-year-old tree, the yield gradually increasing as the tree grows older and more fruit spurs are produced.

The same principles governing other forms apply in the case of bushes and pyramids in the matters of planting, staking, spraying, and manuring, except that phosphates and lime are more necessary than nitrogenous manures.

The best average distance apart at which to plant is 12 ft. Ten feet apart is adequate if the trees are kept closely pruned, are growing on light land, and are not of too spreading a variety; but it is far better to err on the side of greater space than to overcrowd. At these distances currants, gooseberries, raspberries, and strawberries may be grown between for the first ten years at least.

It is most important that the soil near bush fruit trees on dwarfing stocks be *not* dug deeply, as the fibrous feeding roots lie mostly near the surface.

Bushes have the added advantage that the form is eminently suitable to *every* variety of apple, cherry, pear, and plum, with perhaps the

reservation that the finest form of all for sweet cherries, and only sweet cherries, is the full orchard standard, which form is not, however, often suited to the needs of the average garden.—W. P. S.

For hints on PRUNING see *PRUNING FRUIT TREES*.

PYRENEAN DEAD NETTLE.—See *HORMINUM*.

PYRETHRUM (Nat. Ord. Compositæ).—The plants formerly known by this name are now botanically included with the *CHRYSANTHEMUMS*, to the separate articles on which reference should be made. The popular Pyrethrums of the garden are seedling varieties or hybrid forms of *Chrysanthemum coccineum* (Syns. *C. roseum* and *Pyrethrum roseum*). They are of great value in the garden, and are so well known that little description is necessary. The efforts of raisers have given us numerous very beautiful varieties, ranging in colour from pure white to purple, through various shades of blush, pink, rose, and crimson. They differ also in form, some having perfectly double flowers and others with guard florets like an Anemone. The single varieties are also highly decorative, and are much employed for table decoration. Most Pyrethrums flower in May and June, and are indispensable in the border at that season.

Culture.—No special soil is necessary for the successful culture of Pyrethrums, since they will grow well in any good, fertile soil, preferring one of a medium loamy nature, or even light loam, strong clay being the worst soil of all for them. The situation should be sunny, and the ground should be deeply dug and well manured first of all. Opinions differ as to the best time for planting. If purchased in pots this may be done at any time. Spring is a good time for plants not in pots, but the writer prefers to divide and plant immediately after the flowering, giving the plants a good soaking of water to settle them in the soil. Slugs are partial to Pyrethrums, especially when newly planted, hence the frequent losses when autumn or early spring planting is adopted. In many gardens it is necessary to stake the plants so as to keep the stems erect and the blooms flat. This should be done as neatly as possible. If the early crop of flowers is cut as they become past their best a few others will usually be produced in autumn. For this last purpose it is advisable to grow a number of plants in the reserve garden.

Propagating Pyrethrums.—Wonderfully good results may be obtained by sowing seeds, and, if a good strain is purchased, a fair proportion of double-flowered varieties will be obtained. Named varieties can only be propagated by division, which should be done as soon as the first flowering is over, and not in April, as is so often recommended, unless very late flowers are desired. The stools should be carefully cut with a sharp knife so as to allow of at least one crown to each plant. When the weather is dry at planting time it is a good plan to dip the fibrous roots in a puddle of soil and water. The plants should be made very firm in the ground. Seeds may be sown in the same way as those of any other hardy perennial and the seedlings treated in a similar manner to those plants.

What to Grow.—The number of varieties is immense, and most nurserymen have a good selection, frequently under other names, but representing a variety not distinct

from that grown under another name by another dealer. Purchasers are advised to see the plants in bloom if possible, but the following selection contains none but distinct and first-class varieties in their respective colours :—

Selection of Varieties.

Double.—*Alfred Kelway*, crimson ; *Aphrodite*, white ; *Beauty of Laeken*, crimson, anemone flowered ; *Capt. Nares*, crimson ; *Celia*, pink, golden centre ; *Cleopatra*, yellow and white ; *J. N. Twerdy*, crimson, tipped with gold ; *La Vestale*, blush ; *Melton*, crimson-scarlet ; *Othello*, peach-blossom ; *Pericles*, yellow and fawn ; *Queen Mary*, pink ; *Sir James Miller*, crimson ; and *White Aster*, white.

Single.—*Agnes Mary Kelway*, pink ; *Dagon*, rose ; *Dorothy Kelway*, cherry-red ; *Duchess of Brabant*, pink ; *James Kelway*, scarlet ; *John Malcolm*, pink ; *Mrs Bateman Brown*, crimson ; *Mrs William Kelway*, pink ; *Peter Barr*, crimson ; *Pink Pearl*, pink ; *Princess Marie*, white ; and *Purity*, white, tinted blush.—S. A.

For half-hardy sorts see *Annuals, Half-Hardy : List of.*

PYRETHRUM POWDER AND SPRAY. See *Insect Pests : General Methods of Destruction.*

PYRIDINE AND SOAP.—See *Insect Pests : General Methods of Destruction.*

PYROLA (Winter Green. Nat. Ord. Ericaceæ).—This is not a very important genus, but it contains some pretty dwarf-growing hardy herbaceous perennial plants useful for edging, for rock borders, and in the rock garden. They are of very easy culture so long as a lightly shady site and plenty of peat are provided. The best modes of propagating them are by sowing seeds in the summer in the usual way and by division of the roots in March, which is also the best planting period. Care must be taken not to confuse this genus with the medicinal plant known also as Winter Green, namely, *Gaultheria procumbens*. (See article on *Medicinal Herbs*.)

As regards species to grow, *Pyrola chlorantha* (Syn. *P. asarifolia*), *P. elliptica*, *P. minor*, and *P. secunda* are all good. These bear yellowish, white, red, and white flowers respectively in June, and average 3–6 ins. high. *P. rotundifolia* and its variety *asarifolia*, both known as the Canker Lettuce, are found wild, and are of small garden value.

PYRUS.—For the best species see *Trees.*

Q

QUAKING GRASS.—Two kinds of this are useful, the GIANT, and the LITTLE. See under BRIZA in *ORNAMENTAL GRASSES*, and see also *BRIZA*.

QUAMASH.—See *CAMASSIA*.

QUAMOCLIT.—Now included in the genus *IPOMOEA*.

QUASSIA.

This is such a useful material for the gardener that it must be given a short article to itself. It is the standard remedy for Aphis and other leaf-sucking insects, but it is not effective against such leaf-biting creatures as caterpillars.

Quassia chips may be purchased from any good nurseryman or horticultural sundriesman. They are obtained from a tree botanically known as *Picraena excelsa*, and the extract of this wood is an exceedingly bitter substance. Mr. H. H. Cousins, in his little book *The Chemistry of the Garden*, tells us that a ton of Quassia chips contains only 10 oz. of this active principle; but so intense is its flavour that this small amount is capable of embittering most strongly over 24,000 gals. of water.

The preparation of Quassia Wash is a long and tiresome business. At least two days must be taken for this work, and gardeners who have not got the patience or the time to spend on boiling up the liquid are recommended to use proprietary washes instead, so long as they choose those which have been proved to be reliable. Quassia Wash is, very briefly, made as follows:—

Take 1 lb. of Quassia chips and put them into a basin. Cover them with cold water, and allow them to soak for at least twelve hours, giving them a thorough stirring occasionally, say every four hours. Dilute to 1 gal. with water and pour the whole into a saucepan. Put the saucepan on the fire, and simmer the liquid for at least ten hours. One authority recommends the material to be simmered for forty-eight hours on end. Another writer recommends twenty-four hours, in order that the bitter extract may be dissolved from the wood, but the minimum should be ten hours, and if a longer period of boiling is possible do not hesitate to give it. Allow the liquid to cool somewhat, and pour through a fine strainer to remove every trace of woody matter, or the syringe will be quickly blocked up. When the material is thoroughly strained, take another vessel and beat up 10 oz. of the purest Soft Soap that you can get with a little hot water. Mix the soap well with the Quassia extract, stirring meanwhile, and when it has all been added, agitate the liquid thoroughly with an egg whisk, or even by pumping the syringe in it, to be certain that the soap is thoroughly intermingled with the Quassia.

This is what some gardeners call Stock Solution, and it will keep for a short time if it is put into tightly corked bottles, though it is unwise to keep it for any lengthy period. For use, take about one part of Stock Solution and nine of cold water, or if there is much spraying to be done, add 9 gals. of water to the 1 gal. of Stock Solution and thoroughly stir.

This mixture must be used cold or it may burn the foliage. As with other spraying solutions, it is well

not to apply it when the sun is shining very brightly, or burning is almost certain to take place. The liquid must be applied with considerable force through an ordinary garden syringe, the nozzle being directed upwards to wash the creatures completely off. The under sides of the leaves must be treated as well as the upper portion, since Black Aphis and Potato Aphis appear to be fonder of the under sides than any other part.

Some gardeners believe that Soft Soap has an insecticidal value of its own, and that the addition of Quassia is unnecessary to remove Aphis or other leaf-sucking insects. This is quite a mistake. The function of the Soft Soap is to make the Quassia stick on, and it has no insecticidal value whatever. Various other materials such as Nicotine can be added to the Quassia solution in special cases, but if Quassia is thoroughly made as directed it should be quite effective for destroying the Aphis.—E. T. E.

QUINCES.

If the garden has a pond, Quinces will flourish on the banks, where the roots can enter the water. The blossoms are very elegant; the fruits should always be left on the tree into November to perfect growth. They are then useful for jelly or marmalade as well as for flavouring apple tarts. The Pear-shaped is the most generally useful; but the Portugal is larger and less astringent. It helps fertility if the boughs and spray branches are thinned occasionally. The trees succeed in any damp soil, and require no care beyond that usually given to hardy fruit. In a warm season, Quinces may ripen before November. They are fit to gather when deep yellow.

G. B.

QUINCUNX PLANTING.

This is a style of planting in which each plant or tree is opposite a space between two plants or trees in the rows immediately above and below it. The diagram below explains this mode of planting.

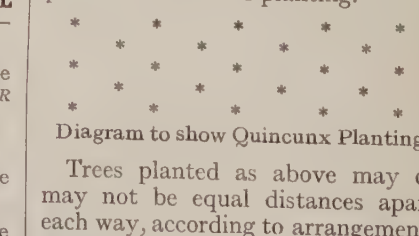

Diagram to show Quincunx Planting.

Trees planted as above may or may not be equal distances apart each way, according to arrangement.

QUINOA.

The leaves of this are used, like those of many other crops, instead of Spinach in districts where the latter will not grow. Quinoa may be cultivated in the same manner as *ORACHE, or MOUNTAIN SPINACH,* which see.

RABBIT BERRY.—The genus SHEPHERDIA. See *SHRUBS*.

RADISH (*Raphanus caudatus* and *R. sativus*. Nat. Ord. Cruciferæ).—The quality of these popular roots depends very much on the growth of the plant. If the growth is slow then the roots will be hot, tough, and uneatable; it is the quickly-grown radishes which are so much enjoyed.

Culture.—For very early supplies, sow seed on a mild hotbed in January. Sowings may be made in a warm border out of doors about the middle of February, other sowings being made every fortnight until August; but owing to the abundance of salads from July onwards, it is the earlier roots that are most highly valued.

Whether radishes be sown in frames or outside, a rich bed should always be provided; the surface soil should be free from stones, and broken down very finely before sowing the seeds. Sow very thinly.

From April until August seed should be set in cool, damp situations, or where water can easily be given during dry weather. Cover the seed very lightly, protecting from birds, which in some districts play havoc with the early batches.

Plants growing in frames must not be coddled, though none but tepid water should be used in watering. After thinning out, give a little air on all favourable occasions.

The earliest outdoor sowings should have the protection of a few bushy sticks, or a light covering of hay or straw placed over them; this covering must not be so dense as to keep light and air from reaching the plants. Fish netting is very useful for covering beds, as this allows the addition of fuller light, protection being given should the weather turn unexpectedly cold after germination. Commence to use the roots as soon as these attain the size of a hazel nut, always pulling from that part of the bed which is most crowded.

Varieties:—*For Summer Use.*—French Breakfast, Icicle, Long Scarlet, Long White, Turnip Radish, and Wood's Frame.

For Winter Use.—Sow in August any of the following:—Black Spanish Long, Black Spanish Round, and China Rose Winter.—F. R. C.

RADISH FLY.—See *INSECT PESTS*.

RAGGED ROBIN (*Lychnis Flos-cuculi*).—See *LYCHNIS*.

RAISED BEDS.

We wonder why these are so common in all gardens which have been made a few years. We can never see anything beautiful about beds raised or mounded up 12–18 ins. or more above the lawn level, and such beds are extremely difficult to dig, plant, or keep gay.

The idea that bedding plants look best when planted on raised mounds is a fallacy. We do not object to beds being raised a few inches; this is at times necessary to show off plants when only one species is used. If the "rising mound" effect is wanted, it can be obtained by other means than by piling on soil; taller varieties of the same genus can, for instance, be planted, or again plants of another, though similar, genus could be set.

Let us hope that high raised beds will die out, for they mean terrible waste of time and labour. Modern gardeners can do better than put

their energies into raised beds; they can spend their time evolving colour schemes, the charm of which is unrivalled.

In gardens where there are many raised beds, it would be a step in the right direction to remove the mound of soil, and deepen the soil below. A bit of extra soil is always useful to gardeners, especially when it is rich soil produced by frequent manuring, as is the case when bedding plants are grown. Then the raised effect can be obtained by planting the dwarfer subjects round the margin with taller specimens in the centre. Good, tall plants are *Antirrhinum majus, Lobelia cardinalis, Schizanthus Wisetonensis, Zinnia Tall Double*, etc.—E.

RAKES.—See *GARDEN TOOLS.*

RAMBLER ROSES. — See *ROSE CLASSES.*

RAMONDIA (ROSETTE MULLEIN. Nat. Ord. Gesneraceæ). — This genus consists of two species which require a shady situation, and succeed best when planted in rocky crevices or joints of stone walls. Both are propagated by means of offsets, or by seeds sown in gentle heat in spring.

Ramondia pyrenaica.—This bears rosettes of green wrinkled leaves, lying flat against the wall. Flowers violet-purple, with orange centres. Site, shade. Soil moist, gritty peat and loam. Flowering Period, May to August. Height, 2 ins.

R. serbica.—The rosettes of smaller leaves of this sort are covered with soft brown hair. Flowers pale blue or mauve. Site, shade. Soil gritty peat. Flowering Period, May to July. Height, 3 ins.

R. serbica Nathaliae. — A form from the Carpathians, with more deeply coloured flowers and bright-coloured anthers.

NEW VARIETIES.

Ramondia pyrenaica pallida.—This bears soft mauve flowers, three to four on a stem.

R. serbica Nathaliae alba.—This has pure white flowers, with an orange ring at their base.

RAMPANT GROWING ROCK PLANTS. See ROCK PLANTS OF RAMPANT GROWTH in *ROCK PLANTS FOR ALL PURPOSES.*

RAMPION (*Campanula Rapunculus.* Nat. Ord. Campanulaceæ).—This plant deserves wider cultivation than it at present receives from all classes of gardeners; the white, fleshy tap-roots being either eaten in a raw state or boiled and eaten as asparagus, while the leaves are highly appreciated in some quarters as a salad.

Culture.—The first sowing to supply roots from August onwards should be made in the open ground early in March. Other sowings may be made at intervals until the end of May to maintain a supply throughout the winter. Wherever possible a semi-shaded position should be selected for the bed, and the land enriched with plenty of well-decayed manure or leaf-soil.

Allow nothing less than a foot between the rows, and early in growth reduce the seedlings to about 6–8 ins. apart. When the plants are well through the soil, give the bed a good hoeing, after which but little trouble need be bestowed upon it.

Some time during the month of November, take up all roots intended for winter use and store between layers of dry sand or earth in a dry shed or outhouse where frost is not likely to reach them. Treated thus, the roots will retain their plump character all the winter.

F. R. C.

RANUNCULUS (*R. asiaticus.* Nat. Ord. Ranunculaceæ).—The Ranunculus family includes the common Buttercup and the King Cup of our meadows; the beautiful double white Fair Maids of France of our mixed herbaceous borders; and the Ranunculus, the once dearly loved and widely cultivated flower of the florists. For some reason this last species has appropriated to itself the name of the whole genus, and it is now invariably the plant that is meant when in garden language a Ranunculus is mentioned.

One hundred and forty years ago the Ranunculus was widely cultivated, and took rank with the Tulip as a florists' flower. Beds of Ranunculuses are, however, seldom seen now, and it is a mystery to the writer to know what becomes of all those that are annually advertised in trade catalogues.

Types of Ranunculus. — There are now three special types on the market, namely, the *French*, the *Persian*, and the *Turban*. They vary in the size of bloom and height of plant. The first of these is the largest flowered and the tallest in stature. The second is the most refined and the shortest in growth, and the earliest to flower. The third is intermediate between the two. The Dutch and the Scotch, which are frequently referred to in lists, usually indicate a special strain of the Persian. The French Ranunculuses are probably hybrids between special strains of the Persian and the Turban or Turkish varieties. They (the French) grow to a height of about 12–18 ins., with good cultivation, and are very effective in a mass.

Culture.—All the types like a good rich soil, but it must not be "rank." They like moisture, but the bed must be well drained, for if there is any stagnant water about the roots, the foliage soon turns yellow. They like shade from the hot afternoon sun, but not shade from overhanging boughs. Those who wish to grow them to perfection should make specially prepared beds. The old soil should be removed to a depth of 20–24 ins. Then some broken bricks or stones put at the bottom and covered with a layer of moss; then the hole should be filled up with the prepared compost, which should be made up of rich mellow loam, old decomposed cow manure, crumbly leaf-mould and sharp sand in about equal proportions. The tubers should be set (claws downwards), with 2 ins. of soil over them. Weak stimulants and regular watering are necessary during the spring when they are making growth, for they must never become dry. Watering must be gradually withheld after the flowers are over, and when the foliage has died down, the tubers may be lifted, dried, and sorted, so that they can be put away until planting time comes round again. In very warm, favoured places Ranunculuses may be planted in the autumn, but for most gardens in the British Isles February or very early March is quite soon enough; even then the young growth must be covered to protect it from severe frosts. It is advisable to cover or surround the claws with sand when planting.

Varieties (FRENCH and PERSIAN).—The names of these vary so much according to the fancy of the seller that no good purpose would be served by giving selections here. Various shades of rose, red, orange, yellow, and pure white are to be found among them. The height averages 12–15 ins.

TURBAN.—The names of these are more fixed than those of the other

two sections, and some of the best named varieties are: *Grootvorst* (crimson); *Hercules* (white); *Merveilleuse* (Nankeen yellow); *Romano* (scarlet); *Seraphique* (citron-yellow); and *Viridiflora* (green with scarlet edge). The height averages about 12 ins.—J. J. & E. T. E.

RANUNCULUS: Perennial Border Species.—Any good garden soil suits these, and they require none but ordinary perennial border culture, being propagated by division of the roots at the usual time, and best planted in February. We recommend the following:—

Ranunculus aconitifolius flore pleno (FAIR MAIDS OF FRANCE).—This is an old favourite, and bears white flowers in May and June, on plants 2 ft. high.

R. acris flore pleno (BACHELOR'S BUTTONS).—This is a double form of the COMMON BUTTERCUP or UPRIGHT CROWFOOT, bearing bright yellow flowers in May, and growing about 2 ft. high.

Rock Garden Species.—Many of the alpine species of this genus are difficult to grow, and consequently no good purpose would be served by describing many here. The following, however, are the easiest to manage, and may be propagated by root division in the autumn or the spring:—

Ranunculus alpestris.—This bears three-lobed leaves in tufts. Flowers pure white. Site, half-shade. Soil very gritty. Flowering Period, June to August. Height, 3 ins.

R. amplexicaulis.—This has tufts of stems and greyish leaves. Flowers white, with golden centre. Site, half-shade. Soil heavy loam, though gritty. Flowering Period, April to June. Height, 12 ins.

R. montanus.—This is another dwarf species. Flowers yellow, and large. Site sunny. Soil moist loam. Flowering Period, May to July. Height, 3 ins.

R. nyssanus.—This has greyish, divided leaves. Flowers citron yellow. Site, half-shade. Soil moist, gritty loam. Flowering Period, May to July. Height, 12 ins.

Water Garden Species.—The best of these are briefly described under CROWFOOT in our article on *WATER GARDEN: PLANTS FOR THE.*

W. I. & E. T. E.

[Species of little garden value or importance are very numerous. The following, though sometimes highly recommended, need not be troubled with except in wild or water gardens: *Ranunculus arvensis,* the DEVIL'S CLAWS; *R. auricomus,* known as GOLDILOCKS; *R. bulbosus,* ST. ANTHONY'S TURNIP; *R. Ficaria,* the PILEWORT; *R. Flammula,* the LESSER SPEARWORT; *R. Lingua,* the SPEARWORT; *R. Lyallii,* the ROCKWOOD LILY; *R. repens,* the CREEPING CROWFOOT; and *R. Thora,* the MOUNTAIN WOLFSBANE.—EDITOR.]

RANUNCULUS: Historical Notes.

This is an old-time florists' flower which has long passed the hey-day of its popularity. Like most of them it was introduced many years ago. It came from the Levant, and the species usually called *Ranunculus asiaticus* is the one from which the florists' varieties were considered to have been the issue. Although the name Ranunculus is derived from the Latin *rana,* a frog, its common early English name was Crowfoot, and the seeker after knowledge concerning its earliest history will do well to remember that name. In old French garden literature a similar fact must be borne in mind—the equivalent name being Grenoillette, Renoncule being the modern one.

In the *Names of Herbes*, by William Turner (1548), he says: "Ranunculus is called in greeke Batrachion, in englishe Crowfote or a Gallande."

The references are so numerous that we can only skim the surface of them, or, properly speaking, only the surface of a few of them. Every botanical and horticultural writer has more or less had something to say about the flower.

Matthiolus in his Commentaries on the Six Books of Dioscorides includes no fewer than six woodcuts of Ranunculuses, with descriptive text, under the chapter headed "*De la Grenoillette*." This was in the French edition published in Lyons in 1579, and twenty-two years later Clusius, in his *Rariorum Plantarum Historia*, devotes about a dozen pages of text and gives twenty-one figures of various kinds of the flower, inclusive of *R. asiaticus*. Of course our own John Gerarde, in his famous *Herbal*, has something to say about the flower. Chapter 351 treats "Of Crowfootes," and twenty-two rough woodcut illustrations of the period enable the reader to follow his descriptions.

Yet another English old-time author, John Parkinson, in the *Paradisus Terrestris*, discourses upon the "Ranunculus. The Crowfoote." Twenty descriptions and some figures are recorded, the last five being varieties of *R. asiaticus*.

Abroad Ferrari, in 1633, in *De Florum Cultura*; Clarici, in his *Istorica*, 1726; Arena, in *Della Natura, e Coltura de' Fiori* in 1768—all Italian writers,—discourse upon the flower. Passing from its single to the double form, it became more and more appreciated. It found its way into the collections of all the famous florists at home and abroad. The Dutch improved it, as they did the Tulip and the Hyacinth, and traded in it most successfully; but the time was fast approaching when the English florist, by aiming at a standard of perfection of his own raising, was to step into the field and, as in the case of some of the other famous florists' flowers, create a far higher and more perfect type, judged by his standard, than had ever been produced by the continentals.

This flower, sometimes called the Turkey, Persian, or Tripoli Ranunculus, was so popular that independent treatises solely devoted to its culture were published quite early in its career, while in most of the old French and other continental florists' books, special cultural treatises on its management were inserted. Pierre Morin, a famous Paris florist of the seventeenth century, gives a descriptive catalogue of both single and double varieties in his garden. The Père d'Ardène published a little volume on its history and culture, which ran into three or four editions—a most interesting, scholarly, and practical little work. Another pioneer eminent in its culture was M. Valnay, who grew a fine collection in the Faubourg St. Germain in Paris in the beginning of the eighteenth century.

We have no Catalogues of the Dutch growers in those days to consult first hand, but Justice, in the *Scots Gardeners' Director*, tells us the Turkey and Persian Ranunculus were then being improved every year by seeding.

Voorhelm and Van Zompel were specifically named as successful raisers, and lists of their gains were given arranged according to colour. These divisions were headed (1) Purple and rose coloured; (2) Orange; (3) White mixed with red; (4) Yellow and red; and (5) Feuille-mort colours. The prices are given at forty guilders per hundred named, but the raisers have some of sur-

prising beauty at ten guilders per root.

Old English florists such as John Evelyn, John Rea, and his son-in-law Samuel Gilbert, help to bring us down to closer times. *The Compleat Florist*, 1740, gives two examples of Ranunculuses that are not quite double, and are wanting when judged by later standards, but the nearer we get to the beginning of the nineteenth century, we find gradual but certain improvement.

Maddock of Walworth, one of the old school of florists, gives an ideal figure of a fine double Ranunculus which accompanies the account of its culture in his *Florist's Directory* (1792). This was one of his specialities, and his collection of them was more numerous than his others, for he possessed over 800 sorts.

From this time onward, and well into the nineteenth century, the Ranunculus became quite a popular exhibition flower, and many are the names of eminent raisers, exhibitors, and growers. From being dependent on the Dutch for their novelties, the English began to raise their own seedlings. Thomas Hogg of Paddington, a writer on the subject, was one; Tyso of Wallingford was another; Dr. Horner, Geo. Lightbody, and others too numerous to be mentioned, followed on. Ranunculus Shows multiplied all over the country—they were mostly held in the village inns and hotels; and this part of the flower's progress can be easily followed up by reference to the periodical floricultural press, in which it was treated with considerable amplitude.

But, like other floral favourites, it had to sustain competition with rival claimants for popular esteem. Towards the middle half of the nineteenth century, interest in the Ranunculus as a show flower began to subside, and the records after the year 1850 show a marked decline in its cultivation and exhibition. Tulips, pinks, pansies, and carnations were given much more prominence; and in 1857, Shirley Hibberd expresses regret that the Ranunculus had then for some years been eclipsed by other floral favourites; that there were then but few professional growers, and that only two florists were then known who traded in the flower to any extent, viz., Mr. Carey Tyso and Mr. Lightbody.—C. H. P.

RAPHANISTRUM.—Now included in the genus *RAPHANUS*.

RAPHANUS (RADISH. Nat. Ord. Cruciferæ).—This is a genus of hardy annuals of no value from a floral point of view. The best known species is *R. sativus*, the COMMON RADISH. See article on *RADISH*, for culture.

RAPHIOLEPSIS.—For best species see *CLIMBING AND TRAILING PLANTS*.

RASPBERRIES.—See *BUSH FRUITS*.

RASPBERRY.—See *BUSH FRUITS* and *MEDICINAL HERBS*, also the genus RUBUS in *SHRUBS*.

RASPBERRY BEETLE.—See RASPBERRY MAGGOT OR BEETLE in *INSECT PESTS*.

RASPBERRY SHOOT BORER and RASPBERRY WEEVIL.—See *INSECT PESTS*.

RAT'S TAIL CACTUS (*Cereus flagelliformis*).—See *CACTI*.

RATS.—See *GARDEN ENEMIES*.

RAW PHOSPHATES.—See under PHOSPHATIC MANURES in *MANURES*.

RECTANGULAR BEDS: AREA OF.—See under AREAS OF BEDS AND BORDERS in *ARITHMETIC AND GARDENING*.

RED ASH (*Fraxinus pennsylvanica*). See *TREES*.

RED-BERRIED ELDER (*Sambucus racemosa*).—See *TREES*.

RED BIRCH (*Betula nigra*).—See *TREES*.

RED BUCKEYE (*Æsculus Pavia*).—See *TREES*.

RED CABBAGE, or Pickling Cabbage (*Brassica oleracea.* Nat. Ord. Cruciferæ).—Where preserves or pickles are in great demand, few more profitable crops than this could be mentioned, a single head of the larger growing varieties often weighing forty pounds or more being sufficient in itself to keep a large family well supplied with pickle for a whole year.

The usefulness of this crop is not confined to pickles, for in some households the smaller varieties are grown for use in exactly the same way as the green varieties, the taste being but little different. Generally speaking, however, the appearance of this in a cooked state is less appetising.

Culture.—Seed may be sown at two different periods of the year: in the spring, or in August and September. Where large size is the main consideration a sowing made during the month of August is recommended. Sow very thinly in an open bed containing plenty of well-decayed manure, leaf-soil or spent hops in order that the young plants may be well supplied with little fibrous roots, without which they rarely bear transplanting as well as most of their tribe. Being quite hardy, no covering is necessary, the plants remaining in the seed-bed until the following spring.

In selecting the summer quarters for these, preference should again be given to a good open site into which manure has been very freely dug and buried well beneath the surface. In planting, well bury the stem of the plant allowing at least 30 ins. between the rows, and the same distance between the plants. If less room is given, the plants, although making large outer leaves, fail to develop hearts of good size and firm texture.

Varieties.—Excellent sorts for garden cultivation are:—Nigger-head, and Ryder's Scarlet Gem.

F. R. C.

RED CEDAR (*Juniperus barbadensis, J. Scopulorum, J. virginiana,* and *Thuya plicata*).—See TREES.

RED CHAMOMILE (*Adonis autumnalis*).—See ADONIS.

RED CURRANT (*Ribes rubrum*).—See BUSH FRUITS, also under RIBES in SHRUBS.

RED CURRANT TOMATO (*Lycopersicum racemigerum*). — See LYCOPERSICUM.

RED DARNEL (*Lolium perenne*).—See LOLIUM.

RED DEADNETTLE, or RED DEAD NETTLE.—See LAMIUM and WEEDS.

RED FIR (*Abies amabilis*). — See TREES.

RED HORSE CHESTNUT (*Æsculus carnea*).—See TREES.

RED-HOT POKER. — The genus KNIPHOFIA and *K. aloides.* See KNIPHOFIA.

RED LARCH (*Larix pendula*).—See TREES.

RED LEAD.—See LEAD COMPOUNDS.

RED MAPLE (*Acer rubrum*).—See TREES.

RED-MILK FUNGUS.—See EDIBLE FUNGI in FUNGI: EDIBLE AND HARMFUL.

RED OAK (*Quercus rubra*). See TREES.

RED-OSIER DOGWOOD (*Cornus stolonifera*).—See SHRUBS.

RED PINE (*Pinus resinosa*) **and RED PLUM** (*Prunus nigra*).—See TREES.

RED SPIDERS.—See INSECT PESTS.

RED TURK'S CAP.—A decorative gourd. See ORNAMENTAL GOURDS.

REDBUD (*Cercis canadensis*) **and REDWOOD** (*Sequoia sempervirens*).—See TREES.

REED.—See ARUNDO and PHRAGMITES.

REED GRASS (*Spartina polystachya*). See SPARTINA.

REED MACE, or REEDMACE (*Typha*). See TYPHA and WATER GARDEN: PLANTS FOR THE.

REELS.—See HOSE REELS in *GARDEN APPLIANCES.*

REFUSE FROM CANNERIES.—See *FISH AS MANURE.*

REGAL PELARGONIUMS. — See *PELARGONIUMS.*

RELATIONS OF PLANT TO SOIL.—See *PLANT PHYSIOLOGY.*

REMOTE BUCKLER FERN (*Nephrodium remotum*).—See *FERNS AND FERN GARDENING.*

RENANTHERA.—See *ORCHIDS.*

RENOVATING OLD LAWNS.—See *LAWNS AND THEIR MANAGEMENT.*

RESEDA (Nat. Ord. Resedaceæ).

Quite a large number of species of this have been described, most of them of little value, which may be treated as half-hardy annuals, hardy annuals, or half-hardy perennials. Quite the most important species is *R. odorata* (see article on *MIGNONETTE*). Other sorts include *R. lutea*, known as BASE ROCKET, and *R. Luteola*, the DYER'S-WEED, which is sometimes foolishly confused with the DYER'S WOAD (*Isatis tinctoria*), described in our article on *ISATIS.*

RESERVE GARDEN.

Head gardeners of big places often put themselves in a difficult position through neglecting to have a Reserve Garden. They sow quantities of various seeds in their frames and find that they have nowhere to prick the seedlings off, or they find they have no reserve stock in case some of the border plants should fail.

We consider it is a very big mistake indeed not to have a Reserve Garden. Even in connection with quite the smaller gardens (so abundant nowadays), it will be found of immense value ; and where complete colour schemes throughout the summer season are aimed at, the Reserve Garden will be found invaluable for keeping fresh stock to fill in gaps when the various plants in the herbaceous border become over.

Annual Plants.—The main stock of these will, of course, be sown in the visible or show borders of the garden, but it is distinctly advisable to sow a few seeds of those which will transplant readily in large circles in the Reserve Garden. They can then be carefully lifted and set in the show borders if need be, or they form a useful means of supplying cut bloom for the home without destroying the floral beauty of the borders. These annuals should be sown very thinly, and crowding must be absolutely avoided, since if it is not, they will not be worth moving.

Biennials.—These plants are dealt with more fully under their various names. They are sown out of doors in the summer, and the Reserve Garden is the right place to sow them in. They can then be pricked out and will be ready for transferring to the winter beds or the herbaceous border in October. It is well to say here that they must be sturdy plants before being put out in their final positions.

Perennial Plants.—When these are raised from seed as they should be by outdoor summer sowing, the Reserve Garden is much better than a frame. They also can be transplanted the same year they were sown, into the permanent positions, after being previously pricked out 6 ins. apart each way in the Reserve Garden.

Other Uses of Reserve Garden.—In part of the Reserve Garden the good soil should be dug out to the depth of 1 ft. and used for the garden. The hole produced should have 3 ins. of broken stone put in, and then be filled up with sifted coke-ashes. The bed resulting is highly useful for plunging plants in, and may be used for winter blooming indoor Chrysanthemums in the summer, and for rock plants in pots throughout the year.

Site for Reserve Garden.—The site should be in full sun, near to a water tap, well, pump, or other means of water supply, sheltered from North and East winds and dry in winter. The soil should be light; if it is heavy it should be lightened by adding plenty of sand or sharp road grit.

Some gardeners use the Reserve Garden as a place for storing composts, manure, etc. This is undesirable. It is better to have a Compost or Manure Yard for this purpose.—E.

RESIDUAL DEPOSITS.—See under SUPERFICIAL DEPOSITS in *GARDEN GEOLOGY*.

RESPIRATION.—See *PLANT PHYSIOLOGY*.

REST HARROW (*Ononis arvensis*).—See *ONONIS*. See also the genus ONONIS in *SHRUBS*.

RESTREPIA.—See *ORCHIDS*.

RESURRECTION PLANT (*Anastatica hierochuntica*, Syn. *A littoralis*. Nat. Ord. Cruciferæ).—This plant, also known as ROSE OF JERICHO, is more curious than beautiful. Its foliage is almost ferny, and is capable of being drawn into a ball, and expanding so that the plant is well over 1 ft. across, according to whether it is kept dry or moist. Full-grown plants keep indefinitely out of soil; we have one by us now which has been kept in a drawer for twenty years, but is expanding just as it used to do long ago. We have never seen the plant in flower ourselves, but others tell us that it bears white blooms in July and onwards, on plants 12 ins. high. It can be raised from seeds sown in gentle heat and pricked off in the usual way for planting out.

Curative Properties.—Many superstitious cures surround the name of the Resurrection Plant, but laying all these aside it does appear to have some curative properties. A mature plant put in a saucer of water and stood in the room day and night will emit a faint but pleasing odour, and this tends to drive off or lessen colds and other similar maladies. Very refreshing sleep is gained by some if a plant is put at the bedside before retiring.

RETARDING.

Gardeners will not find it possible to do this satisfactorily as special cooled chambers are required. Retarded bulbs, corms, or crowns are offered so cheaply, however, that it is certainly not worth while to attempt to carry out the work at home.

REUTERA.—Now included in the genus PIMPINELLA.

REVERSION IN BLACK CURRANT.—See *DISEASES OF PLANTS*.

RHAMNUS.—See under CASCARA SAGRADA in *MEDICINAL HERBS*.

RHAPIS.—For the best species see *PALMS*.

RHAPONTICUM.—Now included in the genus *CENTAUREA*.

RHEUM (RHUBARB. Nat. Ord. Polygonaceæ).—This is a genus of hardy herbaceous perennials, most of which are too coarse for use in the herbaceous or mixed borders, but which come in handy as giant subjects for the wild garden. *R. officinale* is the well-known MEDICINAL RHUBARB. It and *R. collinianum* are good subjects for water gardens (see article on *WATER GARDEN: PLANTS FOR THE*). *R. Rhaponticum* is the even better known GARDEN RHUBARB, famed as a subject for summer tarts (see article on *RHUBARB*). *R. acuminatum*, with its purple flowers in July, and *R. Emodi*, with its white June opening flowers, are useful for the wild garden, and the same remark applies to *R. macropterum*, *R. nobile*, *R. palmatum*, *R. Ribes*, and *R. rugosum*, which bear greenish-white

flowers in the summer, though the variety *tanghuticum* of *R. palmatum* is an ornamental border species. All the above are grown more for their foliage than for their flowers, and range in height from 2 ft. to over 4 yds.

RHEXIA.—See *DEER GRASS.*

RHINOPETATUM.—Now included in the genus FRITILLARIA. See *FRITILLARY.*

RHIPSALIS.—A genus of cactaceous plants. See *CACTI.*

RHIZOBOTRYA.—Now included in the genus COCHLEARIA.

RHIZOCTONIA SCAB.—See under BLACK SPECK in *POTATO DISEASES.*

RHIZOGLYPHUS.—See BULB MITE in *INSECT PESTS.*

RHIZOMATOUS IRISES.—See under NON-BULBOUS OR RHIZOMATOUS SPECIES in *IRISES.*

RHIZOMATOUS PLANTS.—See *KINDS OF CROPS.*

RHIZOME.—An underground stem.

RHIZOTROGUS.—See under CHAFERS in *INSECT PESTS.*

RHODANTHE.—Now included in the genus HELIPTERUM. See *ANNUALS, HALF-HARDY: LIST OF,* and *EVERLASTING FLOWERS.*

RHODIOLA.—A synonym for *SEDUM,* which see.

RHODODENDRON (Nat. Ord. Ericaceæ).—The Rhododendron appears to have been first introduced about 1736. Between then and 1817, several species were introduced from the Caucasus, Gibraltar, the Himalayas, North America, and various parts of Asia, namely, *R. arboreum, R. catawbiense, R. caucasicum, R. maximum,* and *R. ponticum.* Mention must be made of the foregoing species, as it was from these that the first hybrids were raised, and it is noteworthy that some of the earliest raised hybrids still hold their position amongst the best of varieties in cultivation at the present time, notably *R. altaclerense, R. russellianum, R. South Stoneham Scarlet,* and other hybrids of *R. arboreum.*

Of late years, however, crosses have been made with the best of the *Sikkim* and *Bhotan* species and hybrids of *R. catawbiense,* with the result that we now have a race of shrubs combining the hardiness of the latter species with the size of flower, colour, and fragrance of the former.

Rhododendrons rank amongst the most showy and useful of evergreen flowering shrubs, and rightly so, especially when one remembers that the flowering season extends over a period of six months. In exceptional seasons it is possible to have them in flower from September to July.

Culture.—Although Rhododendrons can be grown in soils ranging from grey sand to heavy retentive loams, undoubtedly the most suitable is that of a peaty nature. Districts in which the Scotch Pine luxuriates will be found to suit Rhododendrons admirably. In selecting a situation for planting either in beds, masses, or as single specimens, the conditions under which they thrive and grow naturally should always be borne in mind. One must also remember that the hybrid Rhododendron is really a "manufactured" plant, the greater percentage being grafted on seedling stocks of *R. ponticum.* This species thrives in moist soils and shady situations, and therein lies the whole secret of success, namely, plenty of moisture and partial shade. The latter condition is absolutely necessary if we wish to obtain the very best results as regards growth, and also to bring out the colour of the flowers to perfection. The positions selected should be thoroughly prepared by trenching the ground at least deep enough to break the hard layer of "pan" which is generally present in peaty and sandy soils.

Rhododendrons will repay, by their increased vigour and size of flowers, for fairly liberal manuring. It is a good plan to apply a mulch of decayed cow-manure, when obtainable, one autumn, and the following season to skim over the surface lightly, say about 3 ins. deep, burying in the remains. Failing this, a sprinkling of some approved fertiliser, lightly forked in, will be most beneficial.

An abundant supply of water is, as above mentioned, necessary, more especially as the flowers are opening. When the flowering season is over and growth completed, this is not so important, as rather drier conditions are then more beneficial than otherwise.

All old flower trusses and seed-pods should be removed at the earliest opportunity, not only for appearance sake, but also to relieve the plants of any undue strain.

Propagation. — This may be effected either by seeds, layering, or grafting; the latter process is generally adopted by nurserymen, the most suitable months being January and February. It is not necessary to deal here with the ways and means of grafting, as this falls to the lot of so few gardeners; what concerns us most is how to obtain the best results with the means which we have at our disposal.

LAYERING is best done in early autumn, when the season's growth is completed. All that is necessary is to secure with strong pegs some of the lower shoots of the variety selected for propagation, covering with 2–3 ins. of good peaty soil. In two or three years the layers should be sufficiently rooted to be removed from the parent plant and either set in nursery-beds, or in their permanent positions.

SEEDLING RHODODENDRONS.—Seeds may be sown on well prepared beds in cold frames during February or March, slightly covering the seeds with sharp sand and keeping well shaded until germination takes place. This is not recommended as a general practice, since the results are somewhat uncertain, and, moreover, the process is rather slow. In extreme cases twenty-five years has been known to elapse between the time of seed-sowing and the flowering of the resultant plants.

Rhododendron Species.—In addition to the hybrid and other Rhododendrons named in our selection of varieties, there are a great many species and varieties of species which are of considerable importance in the garden. Their numbers have been greatly augmented within recent years by the introduction of many new species from China. As a rule these last are not yet obtainable from nurserymen, and it has thus been thought wise to omit them from this edition. The species described below are generally of American or Himalayan origin, and as a rule should not be planted in fully exposed positions, since they thrive best in the shelter of, but not under trees. They vary so greatly in size according to age and locality that the heights given are only very approximate. The culture of the species is practically the same as that already outlined. For hybrid species see nurserymen's catalogues, and for the very numerous synonyms see the *Kew Hand-list of Trees and Shrubs*.

Rhododendron Anthopogon. — Bluish-white flowers in March. Height, 1–4 ft.

R. arboreum.—White, crimson, and other coloured flowers from March to May. Height, 10–25 ft.

R. barbatum.—Crimson flowers in April and May. Height, 6–40 ft.

R. brachycarpum.— Yellow or cream flowers in May. Height, 3–8 ft.

R. californicum.— Rose-purple flowers in June. Height, 3–8 ft.

R. campanulatum.—Lilac flowers in April. Height, 6–12 ft.

R. campylocarpum.— Sulphur flowers in June. Height, about 4–8 ft.

R. catawbiense.—Rosy-white and other coloured flowers in July. Height, 3–6 ft. Several of its varieties might be grown.

R. caucasicum.—Yellow or pale pink flowers in August. Height, 1 ft.

R. ciliatum.—White flowers in April. Height, 2 ft.

R. cinnabarinum.— Orange-red flowers from April to May. Height, 6–10 ft.

R. cinnamoneum.—Whitish flowers from April to May. Height, 4–8 ft.

R. Cunninghami (Syn. *Cunningham's White*).—White flowers in April. Height, 2–7 ft.

R. dauricum.—Purple flowers in February. Height, 2–3 ft.

R. decorum.—White or lilac flowers in June. Height, 2–4 ft.

R. Falconeri.— White flowers spotted with purple in May. Height, 6–25 ft.

R. ferrugineum (ALPINE ROSE or ROSE DES ALPES).—Pink or white flowers from May to July. Height, 1–3 ft.

R. formosum.— White flowers tinged with rose in April. Height, 3–6 ft.

R. Fortunei.—Rose flowers in May. Height, 6–20 ft.

R. fulgens.—Blood-red flowers in May and June. Height, 4–6 ft.

R. grande (Syn. *R. argenteum*).—White flowers in March and April. Height, 6–20 ft.

R. griffithianum (Syn. *R. Aucklandii*).—White and other coloured flowers in April and May. Height, 4–10 ft.

R. hirsutum (ROSE DES ALPES).—Pink and white flowers from May to July. Height, 1–2 ft.

R. Hodgsoni.—Rose flowers from May to June. Height, 8–20 ft.

R. Hookeri. — Crimson-scarlet flowers in June. Height, 8–15 ft.

R. kamtchaticum. — Rose-purple flowers in July. Height, 1 ft.

R. Keysii.—Brick-red flowers in July. Height, 2–20 ft.

R. lapponicum. — Red-purple flowers in July. Height, 6 ins.

R. lepidotum.—Yellow or purple flowers in May and June. Height, 2–6 ft.

R. Luscombei.—Rosy-lilac flowers in May or June. Height, 6–10 ft.

R. Maddeni.—White flowers from June to August. Height, 6–8 ft.

R. maximum.—Rosy-white flowers in July. Height, 6–20 ft.

R. Metternichii.—Rose flowers in April. Height, 3–8 ft.

R. myrtifolium. — Lilac-purple flowers in May. Height, 1–2 ft.

R. niveum.—Lilac or purple flowers in May. Height, 3–8 ft.

R. nobleanum.—Scarlet and other coloured flowers from February to March. Height, 6–10 ft.

R. nudiflorum (PINXTER FLOWER).—Pink and white flowers in April. Height, 3–4 ft.

R. Nuttalli. — White flowers in May. Height, 6–20 ft.

R. ponticum.—Purple and other coloured flowers in May. Height, 6–12 ft. Several of its varieties might be grown.

R. praecox.—Rosy-lilac flowers in February and March. Height, 2–6 ft.

R. punctatum (deciduous).—Rose flowers in May and June. Height, 2–6 ft.

R. racemosum.—Rosy-lilac flowers in March. Height, 1–2 ft.

R. serpyllifolium.—Rose flowers in May. Height, 2 ft.

R. Shilsoni. — Crimson-scarlet flowers in May. Height, 6–15 ft.

R. sinense.—Yellow flowers in May. Height, 3–6 ft.

R. Smirnowi.—Purple and scarlet flowers in May. Height, 3–10 ft.

R. Thomsoni.—Crimson flowers in June. Height, 6–15 ft.

R. triflorum.—Pale yellow flowers in May and June. Height, 4–6 ft.

R. viscosum (SWAMP HONEYSUCKLE).—Pink flowers in May and June. Height, 2–4 ft.

R. Wilsoni.—Pink and purple flowers in May. Height, 2–4 ft.

R. yunnanense.—Rosy-lilac flowers in April, sometimes spotted white. Height, 3–9 ft.

SELECTION OF VARIETIES.

The selection which follows is naturally limited, since to describe all the hybrids would need a book as large as this Dictionary itself. As it would only confuse the ordinary gardener to attempt to give the parentage of the varieties, also the synonymous names under which they exist, this data is omitted. All those described below are quite distinct, and are among the very finest in cultivation. Excepting the very earliest kinds, all are quite hardy throughout England and Wales. The varieties described are selected from a collection of over six hundred distinct sorts, and are, we think, best considered under their respective months of blooming.

JANUARY AND FEBRUARY: *R. Christmas Flower.* — Blush-white flowers, splendid if pot grown. Height, 3–4 ft.

R. Jenny Lind. — Pale pink flowers, with chocolate spots. Height, 4–6 ft.

R. nobleanum.—Bright red flowers. Height, 3–4 ft.

R. Sunrise.—Pale red flowers, with a white centre. Height, 3–4 ft.

MARCH AND EARLY APRIL: *R. altaclerense.* — Bright purplish-rose flowers. Height, 4–5 ft.

R. Baron Osy.—White flowers, with a chocolate blotch. Height, 3–4 ft.

R. bodartianum. — Fine white flowers, with dark red spots. Height, 4–6 ft.

R. Gabriel Leibig. — Pale rose flowers, deeper at the edges. Height, 4–6 ft.

R. Handsworth Early White.—White flowers, with pale green spots. Height, 3–5 ft.

R. Jacksoni.—Pale rose flowers. Height, 3–4 ft.

R. Julius Schame.—White flowers, with chocolate spots. Height, 3–5 ft.

R. Mme Scarlet.—Bright rosy-red flowers. Height, 3–5 ft.

R. Mme Wagner.—White-centred flowers, with pink edging. Height, 4–6 ft.

R. Prince Camille de Rohan.—Pale rose flowers, with a dark blotch and crimped edges. Height, 4–6 ft.

R. Professor Reichenbach.—Bright rose flowers and a neat bushy habit. Height, 3 ft.

R. Staatsdame Van Massenbach.—Rose flowers, with chocolate spots. Height, 3 ft.

LATE APRIL: *R. August Van Geert.* — Purple flowers in large trusses. Height, 4–6 ft.

R. British Queen.—White flowers, with pale pink spots. Height, 4–5 ft.

R. Lancashire Witch. — White flowers on which is a heavy chocolate blotch. Height, 4–6 ft.

R. maximum triumphans.—Crimson-scarlet flowers. Height, 3–5 ft.

R. russellianum. — Deep rose flowers. Height, 5–8 ft.

R. Viola. — Pale lilac flowers changing to white. Height, 3–5 ft.

EARLY MAY: *R. Broughtonii.*—Deep rose flowers, lightly spotted. Height, 6–8 ft.

R. cinnamoneum Cunninghami.—White much spotted flowers. Height, 6–8 ft.

R. Comte de Gomer. — White-centred flowers, with a rose edge. Height, 3–4 ft.

R. George Hardy.—Very fine pure white flowers, sparsely spotted. Height, 6–8 ft.

R. Grand Arab.—Dark crimson flowers. Height, 6–8 ft.

R. Helen Schiffner. — White flowers, lightly spotted. Height, 2–5 ft.

R. J. Fiala.—Blush-white flowers, with a heavy chocolate blotch. Height, 4–6 ft.

R. limbatum. — White-centred flowers, edged with crimson. Height, 4–6 ft.

R. Princess Alice.—White flowers, with green markings and a spreading habit. Height, 3–4 ft.

MID-MAY: *R. Alice.* — Bright salmon-pink flowers. Height, 4–6 ft.

R. Chevalier Felix du Sauvage.—Rosy-red flowers, with a heavy chocolate blotch. Height, 3–5 ft.

R. Cynthia.—Bright rose flowers. Height, 3–6 ft.

R. Mammoth. — Pale mauve flowers, light at the edges. Height, 6–8 ft.

R. Manglesii. — White flowers tinged with pink at the edges. Height, 6–8 ft.

R. Memoire de Dominique Vervaene.—White flowers, shaded lilac with heavy chocolate blotch. Height, 4–6 ft.

R. Mrs E. C. Stirling.—Light pink self-coloured flowers. Height, 5–7 ft.

R. Mrs Frank Taylor.—White-centred flowers, edged with bright red. Height, 3–5 ft.

R. Prometheus.—Bright crimson flowers. Height, 4–6 ft.

R. Queen of the West.—Dark mauve flowers. Height, 6–8 ft.

R. Sir Neville Chamberlain.—White-centred flowers, edged with rose, and with a heavy chocolate blotch. Height, 5–7 ft.

R. The Bride.—White flowers, with green spots. Height, 4–6 ft.

LATE MAY: *R. Amphion.*—White-centred flowers, with pale mauve edge. Height, 4–6 ft.

R. bylsianum. — White-centred flowers, edged with scarlet. Height, 3–5 ft.

R. Doncaster.—Brightest crimson flowers. Height about 3–5 ft.

R. F. B. Hayes.—White flowers, with very distinct dark blotch. Height, 4–6 ft.

R. John Walter.—Rich crimson flowers. Height about 4–6 ft.

R. Mdlle Marie Van Houtte.—White flowers with bronze and gold markings on the upper petals, and lightly tinged with pink at the edge. Height, 5–7 ft.

R. Michael Waterer.—Fine dark crimson flowers. Height, 4–6 ft.

R. Mrs Isaac Davies.—White flowers, heavily marked with chocolate. Height, 4–6 ft.

R. Pink Pearl.—Very fine pink flowers. Height, 6–8 ft.

R. Princess Mary of Cambridge.—Pale mauve centre, with darker edge. Height, 4–6 ft.

R. Sappho.—White flowers, with dark purplish blotch. Height, 6–8 ft.

R. Stanley Davies.—Deep crimson flowers. Height, 4–6 ft.

EARLY JUNE: *R. Baroness Schroeder.*—White flowers, with chocolate spots. Height, 4–6 ft.

R. fastuosum flore pleno.—Fine double mauve flowers. Height, 6–8 ft.

R. Kate Waterer.—Bright pink flowers spotted with yellow, and with a white blotch on the upper petals. Height, 4–6 ft.

R. Lady Clermont.—Dark crimson flowers, with a heavy black blotch. Height, 6–8 ft.

R. Lady Mosley.—White flowers, shaded with lilac and with bronze spots. Height, 5–7 ft.

R. Mme M. Chasselas Laulat.—White flowers, edged with lilac and lightly spotted. Height, 4–6 ft.

R. Mme Marcel Moser.—Light crimson flowers. Height, 6–8 ft.

R. Mrs R. S. Holford.—Salmon-pink flowers. Height, 6–8 ft.

R. Nellie Moser.—Light pink-spotted flowers. Height, 4–6 ft.

R. papilionaceum.—White flowers, with bronze markings. Height, 4–6 ft.

R. Purity.—Pure white flowers. Height, 4–6 ft.

R. T. H. Kekewich.—Deep purplish-crimson flowers. Height, 4–6 ft.

MID-JUNE: *R. Bruce Finlay.*—Dark red flowers, with a black blotch. Height, 4–6 ft.

R. Duchess of Connaught.—White flowers, with a heavy yellow blotch. Height, 3–5 ft.

R. Eclipse.—Dark plum-coloured flowers, with bronze markings. Height, 4–6 ft.

R. Gomer Waterer.—Very fine white. Height about 4–6 ft.

R. Helen Waterer.—Crimson-edged flowers, with light centre. Height, 4–6 ft.

R. James Nasmyth.—Bright rose flowers, with heavy chocolate blotches. Height, 4–6 ft.

R. Lady Hillingdon.—White flowers, shaded with violet. Height, 6–8 ft.

R. Lord Powerscourt.—Crimson flowers, with heavy black blotches. Height, 4–6 ft.

R. Lord Roberts.—Rich crimson flowers. Height about 3–5 ft.

R. Mme A. Moser.—Pale mauve flowers, with a heavy yellow blotch. Height, 6–8 ft.

R. Mrs Tritton.—Carmine-edged flowers, with a lighter centre. Height, 4–6 ft.

R. Mrs W. Agnew.—Pale rosy-pink flowers. Height, 4–6 ft.

LATE JUNE AND EARLY JULY: *R. Beauty of Bagshot.* — White flowers, with distinct bronze markings. Height about 4–5 ft.

R. C. S. Sargent.—Bright purple flowers. Height about 5–6 ft.

R. Decorator.—White semi-double flowers, shaded with lilac, and with bronze markings. Height, 6–8 ft.

R. J. H. Agnew.—Fine pale pink flowers, with a dark blotch. Height, 6–8 ft.

R. J. J. Moser.—Dark crimson flowers, with a heavy black blotch. Height, 4–6 ft.

R. Joseph Whitworth.—Intense crimson purple flowers. Height, 4–6 ft.

R. Lady Annette de Trafford.—Pale rosy-pink flowers, with a dark blotch. Height, 4–6 ft.

R. Lady Clementine Mitford.—Rose-pink flowers, with a dark blotch. Height, 4–6 ft.

R. Lady Clementine Walsh.—White-centred flowers, changing to pale rose at the edge. Height, 3–5 ft.

R. Lady Mary Compton.—White flowers, with a yellow blotch. Height, 6–8 ft.

R. Mme Jules Porges.—Lilac flowers, with heavy chrome-yellow blotches. Height, 6–8 ft.

R. Mrs Mendel.—Bright satiny-pink flowers, with bronze markings. Height, 4–6 ft.

Fragrant Rhododendrons. — We cannot conclude without a brief reference to some of the best hybrids which emit a pleasing scent. We recommend the following, all of which are quite hardy :—

R. Duchess of York.—Salmon-pink flowers, marked with yellow and green, in early June. Height, 3–5 ft.

R. Duke of York.—Dull rose flowers, with a darker blotch, in early June. Height, 3–4 ft.

R. H. M. Arderne.—Rich rose flowers, with a darker blotch, in mid-May. Height, 3–5 ft.

R. Helen Paul.—Pale rose flowers, suffused with yellow, in mid-May. Height, 3–4 ft.

R. kewense.—Large pearly-white flowers, in early May. Height, 3–5 ft.

R. Lady Thistleton Dyer.—Rich salmon-rose flowers, with a darker blotch, in early May. Height, 3–5 ft.

R. Mrs Arderne.—White flowers, shaded with lilac, in early June. Height, 3–5 ft.

R. Mrs Webley.—Light rose flowers, with a dark blotch, in early June. Height, 6–8 ft.

R. Profusion.—Pale rose flowers, with a light centre, throughout May. Height, 3–5 ft.

R. Sir Charles Butler.—Pearly-white flowers, with a yellow centre, in early May. Height, 3–5 ft.

C. N. & S. A.

NEW VARIETIES.

R. Bagshot Ruby.—Ruby-red bell-shaped flowers in large trusses.

R. Diphole Pink.—Rose-pink flowers, with orange spots on the top segments.

R. Donald Waterer.—Silvery-pink flowers, with orange spots on the top segments.

R. Duchess of Teck.—White flowers suffused with pink, which deepens at the margins, and spotted with orange.

R. Ernest Gill.—Deep rosy-crimson flowers, often 3 ins. across.

R. fastigiatum.—Light blue flowers in clusters, and dark green box-like leaves.

R. Gill's Goliath.—Rosy-blush flowers, netted, and darker outside.

R. Gillii.—Bright red bell-shaped flowers, netted with crimson veins.

R. lepidoboothii.—Salmon-white flowers produced in umbels.

R. Liliani.—Red flowers in large trusses above long leaves, which are bright green on the top, and yellow-green underneath.

R. Littleworth Hybrid.—White bell-shaped flowers, with purple markings at the base, in very large trusses.

R. Loderi Diamond.—White flowers, flushed with pink, in large trusses.

R. Loderi Pink Diamond.—Bright pink flowers in large trusses.

R. Masterpiece.—Pure white flowers on plants of dwarf habit.

R. Roylei magnificum.—Large salmon-red flowers, with leaves which are glossy above and grey beneath.

Excepting *R. Masterpiece*, all the above are quite hardy and suitable for culture outside.—W. J. C.

[The above are only a few of the very best of the new sorts. Novelties are being constantly introduced, and those who want the latest information should consult the lists issued by shrub specialists.—EDITOR.]

RHODODENDRONS: TOP-DRESSING FOR.—See *TOP-DRESSING.*

RHODOTYPOS.—For the best species see *SHRUBS.*

RHOPALOSTYLE.—For the best species see *PALMS.*

RHUBARB (*Rheum Rhaponticum.* Nat. Ord. Polygonaceæ).—This is one of the easiest of all crops to grow; in fact it is largely owing to the accommodating nature of the plant that we so seldom find others than professional growers devoting anything approaching the proper attention so useful a crop deserves. Any out-of-the-way corner is thought by many to be good enough for this, yet those professionals whose position justifies their opinion carrying some weight agree that no crop in the garden is likely to give more profitable return for good treatment than this; and as the quality of the sticks is largely determined by the

cultivation the plant receives, one well-grown stick having more value than half a dozen weak ones of a tough and stringy nature, this course is advised wherever practicable.

Culture.—New beds may be formed by planting single eyes taken from old shoots any time from January until the end of March, perhaps the best time for making these being just previous to the crowns breaking into new growth. Whenever possible select a good open situation for the crop as far away from the shade or drip of overhanging trees as can be managed, and if the bed is to remain undisturbed for a number of years, or where strong crowns for forcing are wanted, trenching of the soil instead of ordinary digging should have preference. During this process well-decayed manure should be freely mixed with both the lower and upper spit of soil.

Not less than 3 ft. should be allowed between the rows and about 2–3 ft. between the plants.

Good strong portions of old roots containing but a single eye are preferable to those carrying several weak ones; these should be planted firmly in the ground with the eyes barely covered with soil; and after planting little or no attention will be needed until the shoots begin to push up, after which the hoe should be kept in constant use between the rows and water freely applied during dry weather.

Gathering.—No pulling must be attempted the first season after planting, and only a very limited number of sticks taken during the second, but where liberal doses of strong liquid manure can be poured over the bed, this should be done throughout the second period of growth. Where this treatment is given, the crowns will be strong enough for forcing the following winter, or if left undisturbed may be freely drawn upon for use the next summer.

From Seed to Forcing.—Rhubarb may easily be raised from seed sown in light soil any time during early spring, care being taken to keep the beds free from weeds. Seed may also be sown in heated houses or frames and the seedlings pricked out into beds of finely sifted soil; but as the seed rarely produces plants true to type, the majority being of inferior quality, this method of increasing one's stock is rarely adopted, and is not recommended.

Rhubarb may be forced into growth during the winter months by taking up the strongest crowns and packing them closely together in boxes, or on the floor of a warm greenhouse. Complete darkness and plenty of moisture ensures a rapid and highly coloured growth, the use of tepid water or weak liquid manure being advisable after the crowns burst into growth.

Forced Rhubarb may also be had from plants growing in the open air, by simply covering the strongest crowns with large pots, baskets, boxes, or chimney pipes, these being afterwards covered with nearly fresh horse manure or a mixture of manure and leaves. The period between the time of covering up and the pulling of fair-sized sticks is entirely governed by the amount of material placed around the first coverings, or the period of the year when forcing is attempted.

Varieties.—The following are splendid sorts for garden culture and forcing. The variety *Crimson Winter* or *Everbearing* given below is specially useful:—Crimson Winter or Everbearing, Daw's Champion, Early Champagne, and The Sutton.

F. R. C.

RHUBARB.—See *RHEUM* and *WATER GARDEN : PLANTS FOR THE.*

RHUS.—See *POISONOUS PLANTS* and *SHRUBS.*

RHYNCOSTYLIS.—See *ORCHIDS.*

RIB GRASS (*Plantago lanceolata*).—See *PLANTAGO.*

RIBBON FERN (*Pteris serrulata*).—See *FERNS AND FERN GARDENING.*

RIBES.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

RIBWORT PLANTAIN.—See *WEEDS.*

RICE GRASS (*Leersia oryzoides*). —See *LEERSIA.*

RICHARDIA.—See *ARUM LILIES.*

RICINUS (CASTOR OIL PLANT. Nat. Ord. Euphorbiaceæ).—This is a noble large ornamental-leaved plant of majestic appearance, and is an annual of rapid growth. Seed should be sown in warmth about March, and each seed sown in a separate small pot to prevent injury to the roots. The plant can also be used for sub-tropical gardening, and a good rich loam produces the finest growth. Temperature required, 40–50° F.

Greenhouse Species. — *Ricinus Africanus.* — Large green foliage. White flowers from May to September. Height, 2–6 ft.

R. cambodgensis.—Best dark leaf. Green flowers from May to September. Height, 1½–3 ft.

R. communis major (CASTOR OIL PLANT). — Green flowers from May to September. Height, 1½–5 ft.

R. Gibsonii.—Dark purplish stem and foliage. Green flowers from May to September. Height, 1½–5 ft.

R. macrocarpus.—White flowers and stem, also light green leaves. Flowers from May to September. Height, 1½–5 ft.

RIDDLES.— See under SIEVES in *GARDEN APPLIANCES.*

RIDGE CUCUMBERS.—See article on *CUCUMBERS : OUTDOOR.*

RIDGING.—See ROUGH DIGGING AND RIDGING in *SOIL CULTIVATION.*

RIGHT TO PRUNE HEDGES : LAW AS TO.—See *GARDENING LAW.*

RIGID BUCKLER FERN (*Nephrodium rigidum*).—See *FERNS AND FERN GARDENING.*

RINGING.— See under LAYERING in *PROPAGATION OF PLANTS.*

RIVER BIRCH (*Betula nigra*). —See *TREES.*

RIVER SAND.—See *SAND.*

RIVERBANK GRAPE (*Vitis vulpina*). See *CLIMBING AND TRAILING PLANTS.*

ROAD SAND.—See *SAND.*

ROBBERS.—See *GARDEN ROBBERS.*

ROBERTSONIA.—Now included in the genus *SAXIFRAGA.*

ROBIN'S PLANTAIN (*Erigeron bellidifolius*).—See *ERIGERON.*

ROBINIA.—For the best species see *TREES.*

ROCAMBOLE.

The bulbs of this are used for flavouring purposes, but are not often required. The culture is the same as that of *GARLIC*, which see.

ROCK ABELIA (*Abelia chinensis*).—See *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

ROCK AND ALPINE PLANTS DISLIKING LIME.—See *LIME-HATERS.*

ROCK BANKS.—See *BANKS.*

ROCK BORDERS.

The present writer well remembers a correspondence in a horticultural newspaper respecting *Undesirable Plants in the Rock Garden.* This correspondence lasted for several months, and it was interesting to see the various views which were expressed. The view held personally was that very few plants were really unsuitable or undesirable in the rock garden, but that a good many of the more rampant subjects were extremely suitable for what is known as the rock border. In the present notes we propose, first, briefly to deal with the making of rock borders, and then to suggest a few subjects which are quite suitable for them.

Making the Border.—The making of rock borders is a far more simple task than is the construction of a rock garden. The building of a proper rock garden is hard work indeed, and needs a certain amount of skill, as well as an aptitude for fitting stones together. Not so the rock border. All that is necessary can be done by any gardener who has an eye for the natural lie of stone. The first thing to do is to dig the proposed rock border over to the depth of 2 ft., and thus to ensure that the drainage is sufficiently great to carry off surplus water. Some light leaf-soil, old mortar rubbish, or similar material should be dug into the border if the soil is at all heavy, and some old hotbed manure if the mould is light. As to the stones, any stones suitable for rock garden building are more or less suitable for the rock border. See article on *Rock Garden: Making a.*

Regarding the setting of the stones we may mention that they may be let into the ground in almost any direction provided that they are not perched up on end. As a lady friend of ours said, "Stones perking out of the ground in an upright position look absurd," and certainly a rock border with stones set on end looks highly unnatural. We prefer to use stones which are somewhat rectangular in shape—with the length greater than the breadth. The stones are then let into the ground at a slight angle, in the direction of their length, and groups of them are let in at approximately the same angle to imitate the natural dip of a bed of rock. Other groups should dip in other directions, again to imitate nature, for out in the country two or three dips in different directions may often be seen within a few yards of each other, due to what geologists know as "faulting." The great mistake when making a rock border is not to set the stones in the ground firmly enough. Plants cannot thrive amongst loose material, a fact which should be borne in mind by every lover of flowers. The best time for making rock borders is between November and the middle of March, and the ideal time for planting is early in February, provided that the weather is suitable. Seeds of rock plants may be sown any time from April onwards, and the only after culture needed by rock borders is the keeping of them free from weeds, and the annual dressing of them with light leaf-soil or rotted manure.

Some Suitable Subjects.—When we come to consider the question of suitable subjects for rock borders we are literally amazed by the number available. Herbaceous plants such as Erigerons, Heleniums of the dwarf kind, and indeed many similar plants ranging in height from 1 ft. to 18 ins., will do better in the rock border than in the herbaceous border, although they may not be true rock plants. Frequently in town gardens, where the soil is somewhat sour, plants will fail if grown in the ordinary way, but if grown in the rock border made with limestone (not too much stone being used for the purpose), they will thrive and flower profusely.

The first subject that occurs to us is found in the genus Achillea. *A. argentea* and *A. rupestris* flower in the summer and bear white flowers, and are very suitable, though they are only about 6 ins. high. Some of the taller Achilleas are also good. *Æthionema coridifolium* is a pink-flowering plant blooming in June and August. Height, 8–12 ins. This, with other Æthionemas, is a successful plant. Most suitable, indeed, are the Ajugas. These are considered too rampant for the

rock garden, as they spread by underground roots. *Ajuga genevensis Brockbanki* is a blue June flowering species, and is about 8 ins. in height.

We need hardly refer to the extraordinary value of the perennial Alyssums as rock border plants. *A. saxatile* in its two varieties, both yellow, will produce a show of glorious colour if large patches of it are planted in the rock border. *A. argenteum* is a little taller, and is also eminently suitable. These Alyssums range about 6–12 ins. in height. Arabis, too, is a well-known rock garden plant, which is too rampant for the tastes of some. Grown in a rock border, however, among plenty of stones its ardour is not checked to any great extent, and its double white flowers, with the pink blooms of *Arabis aubrietioides*, are too lovely to dispense with. These plants range about 3–8 ins. high.

Alpine Asters are also useful for the rock border, but Aubrietias are far and away ahead of them. The glorious variety *Fire King*, with its red April-borne blooms, the princely purple of *Dr Mules*, and the soft rose-pink of *Moerheimii*, are at the worst wonderfully attractive plants. Many Campanulas are also suitable. *Campanula carpatica*, for instance, a plant of about 1 ft. high, and that glorious little plant *Campanula muralis*, are both blue-flowering subjects which will do well in the open rock border. The latter averages about 3–6 ins. in height.

Cerastium Biebersteinii and *C. tomentosum* are, however, probably the most perfect rock border plants of all. Their silvery-grey foliage and pure white blooms make them distinctly attractive. In the summer months the whole of the plants are covered with a sheet of white flowers, and hence they are known by many people as SNOW IN SUMMER. Many of the Dianthi, Drabas, with Edraianthus (Syn. *Wahlenbergia*) and Geraniums, are also good.

Our next plant of high order of merit for this purpose is found in the Helianthemum, often known as the Sun Rose. The various varieties of *Helianthemum vulgare* are rich in gorgeous colours, and many a bright spot in a long rock border will be found if Helianthemums are planted. Iberis or the Perennial Candytuft, Linarias, especially *Linaria pallida*, Lithospermums, and *Lychnis alpina*, are most desirable rock border plants. Of special merit, however, is *Nepeta Mussini* or Catmint, except where cats are numerous. In such cases Catmint should be banned, for the quadrupeds will make their resting-place on one's beautiful rock border and completely spoil the plants.

Alpine Phloxes, Primulas, and Saponarias are also good, and of the genus Saxifraga there are many suitable types. The taller Saxifrages of all sections are exceedingly useful, and many of the dwarfer sorts, which are easy to grow, may also be commended. Of the first *Saxifraga Fortunei, longifolia, mutata*, and *peltata* are good, while of the latter section such as *Apple Blossom, Cherry Trees, Elizabethae, oppositifolia, Red Admiral*, and *Wallacei* may be mentioned. Most of the taller Sedums, Sempervivums, and Silenes are also suitable.

This by no means exhausts the vast number of plants which are available, for, as mentioned earlier, their name is legion. We must, however, mention two more subjects before closing, namely, Veronicas and Vincas. Of the first, such sorts as *Veronica gentianoides, prostrata*, and *saxatilis*, which are violet and blue in colour, may be mentioned, while *Vinca minor*, with its pretty

blue, purple, and white colours, is quite indispensable.—E.

ROCK CEDAR (*Juniperus tetragona*). See *TREES*.

ROCK CRESS. — See *ARABIS* and *CRESS*.

ROCK-CRESS, PURPLE.—See *AUBRIETIA*.

ROCK ELM (*Ulmus racemosa*). —See *TREES*.

ROCK GARDEN BULBS.

The effectiveness of the rock garden can be greatly enhanced by the use of bulbous and tuberous-rooted plants, many of which come into bloom early in the year, and in advance of the ordinary rock garden subjects. The ground can be carpeted with dwarf creeping plants, through which, if the growth is not too dense, the bulbs will push their way, flower, and die back till the following season. No plants are of easier culture; they will thrive in any good, light soil, such as is usually to be found on the rockery, and merely require to be planted from 2 to 5 or 6 ins. deep, according to the size of the bulb. Crocuses, however, should be planted very shallow.

Autumn-flowering Bulbs. — Colchicum in variety—leaves do not appear till spring; *Crocus asturicus, C. iridiflorus, C. longiflorus* (Syn. *C. odorus*), *C. medius, C. ochroleucus, C. pulchellus, C. Salzmanni, C. sativus* (the source of Saffron), *C. speciosus, C. s. Aitchisonii, C. Tournefortii, C. zonatus; Cyclamen africanum* (Syn. *C. macrophyllum*), *C. cilicium, C. europaeum, C. neapolitanum* (Syn. *C. hederaefolium*), *C. n. album; Leucojum autumnale; Scilla autumnalis, S. a. japonica; Sternbergia lutea, S. macrantha.* All these plants are of dwarf habit, the tallest being the Colchicums.

Winter-flowering Bulbs. — *Anemone apennina, A. blanda, A. fulgens; Colchicum Decaisnei; Crocus ancyrensis, C. biflorus, C. hyemalis Foxii, C. Imperati, C. Sieberi, C. tommasinianus, C. vitellinus; Cyclamen cilicium, C. Coum; Eranthis hyemalis;* Galanthus in variety; Hepatica (Syn. *Anemone Hepatica*) in variety; *Iris alata, I. Bornmülleri* (Syn. *I. Danfordiae*), *I. persica, I. reticulata* and varieties, *I. Sindpers, I. unguicularis* (Syn. *I. stylosa*), *I. Vartani; Muscari azureum* (Syn. *Hyacinthus azureus*) and varieties; *Narcissus Bulbocodium* and *N. minor minimus.* These plants are all of dwarf habit, and bloom at varying periods between December and early March, much depending on the nature of the season, and the shelter and aspect they enjoy. Under favourable circumstances many of the bulbs included under the heading of Spring-flowering will also bloom before winter is over.

Spring-flowering Bulbs. — *Allium Moly* (height, 1 ft.), *A. neapolitanum* (height, 15 ins.), *A. ostrowskianum* (height, 6 ins.); *Anemone coronaria* in variety (height, 1 ft.), *A. hortensis* (Syn. *A. stellata*) in variety (height, 6 ins.), *A. nemorosa* in variety (height, 6 ins.), *A. ranunculoides* (height, 6 ins.); *Bulbocodium vernum* (height, 6 ins.); Chionodoxa in variety (height, 4 ins.); Crocus in several species; *Cyclamen ibericum* in variety (height, 3 ins.), *C. repandum* (height, 3 ins.); Erythronium in many species and varieties (height, 3–9 ins.); Fritillaria in variety (height, 9–18 ins.); *Iris bucharica* (height, 12 ins.), *I. caucasica* (height, 6 ins.), *I. cristata* (height, 3–4 ins.), *I. Heldreichii* (Syn. *I. stenophylla*) (height, 4 ins.), *I. orchioides* (height, 12 ins.), *I. Sisyrinchium* (height, 6 ins.), *I. Warleyensis* (height, 12 ins).; *Leucojum vernum* (height, 4–6 ins.); *Milla* (Brodiaea) *uniflora* (height, 6 ins.); Muscari (height, 6 ins.);

Narcissus cyclamineus, N. juncifolius, N. triandrus (all about 9 ins. high); *Puschkinia scilloides* (height, 6 ins.); Romulea in variety (height, 6–9 ins.); *Scilla bifolia, S. italica, S. sibirica, S. unifolia, S. verna* (all about 3–6 ins. high); Sparaxis in variety (height, 6 ins.); *Sternbergia fischeriana* (height, 6 ins.); *Tulipa Batalinii, T. Clusiana, T. persica, T. primulina* (height, 6–12 ins.).

These plants flower at varying times from March to May or early June. Those mentioned by no means exhaust the list.

Summer-flowering Bulbs.—*Allium pulchellum* (height, 9 ins.), *A. p. flavum* (height, 9 ins.); *Anomatheca* (Lapeyrousia) *orientalis* (height, 6–9 ins.), *A. grandiflora* (height, 9 ins.); Brodiaea in variety (height, 9–18 ins.); Calochortus in variety (height, 6–24 ins.); *Oxalis floribunda* (height, 8 ins.), lift in autumn; and *Tritonia crocata* (height, 6 ins.).—W. J. C.

ROCK GARDEN : FOLIAGE PLANTS FOR. See *FOLIAGE PLANTS FOR ALL PURPOSES.*

ROCK GARDEN : MAKING A.

Rock gardening appeals with singular force to the amateur either as a hobby or as a pastime. It can be carried out in limited space, the initial outlay is never burdensome, and the maintenance in after years does not run to a fraction of what bedding plants cost; the display is infinitely greater and the pleasure more satisfying, while the practical work inseparably associated with rock plants affords the most healthy relaxation from business work and worry.

The Site of the rock garden is of first importance. Wherever possible, choose a sunny position in the open, away from high walls and large trees. Some shelter to the north and east is desirable, but this can be supplied by planting a few hardy shrubs of moderate growth near to the rock garden to act as a screen against cutting winds. The objection to tall trees is twofold: the branches cause shade and drip in wet weather, which is fatal to good plants; and the tree roots soon find the good soil, and in a few years will exhaust it. High walls act in a similar way, by preventing a free circulation of air. They also cut off much of the natural supply of rain.

Having decided upon the site, we now consider the form or shape of the rock garden. In this direction taste has great latitude, for a rock garden may be anything from a low, almost flat, series of undulating beds or mounds, up to terraced hills of soil studded or built up with rock-masses many tons in weight. As the latter require specialised treatment in the hands of experts, I shall confine myself to material that any amateur can handle by himself. The low style of rock garden is as good as any, so far as plant growth is concerned; its only drawback being that it does not lend itself to spectacular effect. Boldness and a certain amount of rugged aspect, such as we seek to reproduce in miniature hills and gorges, can only be secured by stone built up to form a rocky mass. In this way the size and height of our rock garden is largely determined by local conditions: if stone is scarce and we wish to use it to the greatest advantage, then the low type of rock garden is best for our purpose; with plenty of stone this limitation does not arise. It is quite an erroneous idea to suppose that large quantities of rock are necessary or desirable; many rock gardens suffer from a surfeit. Even when stone is purchased, a few well-chosen pieces are far better than

unlimited quantities of small waste, that calls for endless labour and ingenuity in building.

The outline of the rock garden, that is, the point of contact, all round it, at ground level, should be irregular; avoid curves and sweeps that are mathematically correct, and do not make a continuous margin of stone; but make the intervals of stone and soil irregular and give each bay or projection a touch of character of its own. Then, the weight and balance of the rock garden must be kept in view when setting out. In small gardens it is never advisable to attempt anything too elaborate; simplicity should be the key-note throughout. If one point is selected to carry the weight, let it be treated boldly on simple lines; if few stones are available use them where they will be most effective. Suppose the ground is flat, narrow, and of moderate length, then the highest point may either be the centre or one of the ends. If the first arrangement is followed, raise one end about two-thirds the height of the centre, and the other end about half the height of centre. In the other arrangement, by placing the highest point at one end, a second point two-thirds the height of this can be raised at the other end, and the interval between treated as valley, slope, or boulder-strewn incline. On steep or undulating ground it is much easier to secure a natural effect with rock-work, and the balance is also simplified, because here, the highest point should incline in the direction of the natural rise of the ground: the point I particularly want to emphasise is, strive in all building and arrangement to make the rock garden appear as an outcrop or natural feature of the position, and not as a forced growth having no sympathy with its surroundings.

And now, a word as to stone; if this can be had locally by all means use it, unless it is of a nature that crumbles readily on exposure, or magnesian limestone. In this latter case its whiteness will always be an eyesore, so it is best avoided. When stone has to be purchased, then good limestone or sandstone are best; it is immaterial whether the latter is white or red as it very soon weathers and greens over, and loses its new appearance. Artificial material in the way of cement or concrete should be avoided as far as possible; it is really only useful in binding small stone together to form a promontory or projecting point: when exposed to the air it sooner or later suffers from the action of frost.

Building.—The actual building of the rock garden should invariably begin at ground level, and the first stones should have their lowest edge concealed. Make them always to dip or incline toward the main body of soil in which they rest: at times this may be arranged to give a flat surface, when they can be used as stepping stones to gain access to the plants; at other times a diagonal tilt to right or left may be more effective; but whatever inclination is set up in the lower stones, observe this sequence throughout and a definite stratification will result. Avoid the regular effect of spiky pinnacles as shown in Fig. 1, where the stones appear as if they had been spaced off by footrule, and their most glaring surfaces exposed in each case. In Fig. 2 a better arrangement is illustrated; the stones follow a definite line, the ends in the soil are concealed and firmly bedded, and no amount of treading upon them is likely to loosen or dislodge them. The plants also are better placed, the larger growth

in particular being used to half-veil the stones or accentuate their height. In any arrangement similar to this, a quantity of smaller stone can be worked in, and the larger pieces spread over a greater surface; but with small stone only a quarter to one-third of it can be exposed; at least two-thirds of it must lie buried in the soil and be made absolutely rigid, as no good alpine will grow satisfactorily when stones are loose or cockle whenever hand or foot is placed against them.

A suggestion for dealing with small stones of more or less even thickness is shown in Fig. 3. The main objection to such an arrangement lies in its wall-like face, but this could be largely destroyed with careful planting: its merit consists of the abundance of crevices it furnishes for the better class of alpine plant life; the stones, as I have shown them, lie rather close together, but this can easily be varied by making the joints wider, occasionally using a small chip of stone to keep them apart; provision is made for a small path half-way up. Rocks arranged in this fashion are best planted as they are laid. Whatever arrangement of laying stone is followed, the idea of forming crevices for the choicer plants should be kept well in the foreground. Different aspects must also be provided, and in this way the requirements of various plants satisfied. In Fig. 4 is shown an arrangement that must at times be resorted to in building

FIG. 1.—A spiky arrangement; rocks and plants at too regular intervals.

FIG. 2.—A more tolerant arrangement; rocks arranged in better series, or layers, and plants better placed. Note the lower edge of stone and also one end are both concealed.

a promontory with small stone, so as to secure a bolder effect than usual, and also to raise the ground

FIG. 3.—The natural home of alpines is in fissure and crevice—small stones arranged in this way provide both, in endless variety and always well drained.

from being too severely flat; the method of holding the stone together should be carefully noted, and in building, pack all spaces between the stones with soil and ram firmly, planting as the stones are laid. This method answers admirably on the north side of the rock garden, and the vertical

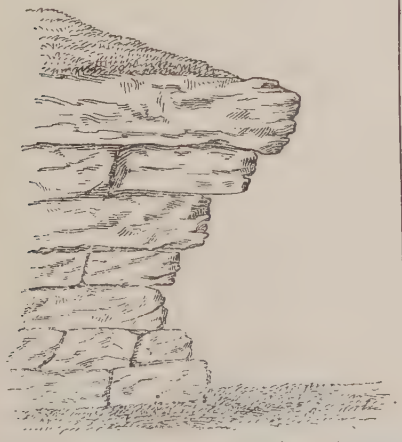

FIG. 4.—Method of arranging stones to form a bold point or to lift the ground sharply.

NOTE.—In practical work use this method to form a north aspect; the overhanging stones are more troublesome to plant if placed in the sun.

fissures that result make ideal positions for Ferns, Haberlea, Primulas, and Ramondias. This idea last commented upon is useful in another direction, for if water can be laid on, and the faintest trickle allowed to fall over the topmost stone, a delightful dripping will result. To catch the water a small basin or pool can be formed of concrete, or it may be made watertight with well-puddled clay. Perhaps the happiest idea would be to carry a small channel or rivulet from the dripping well pool, and make the larger pool more to the south of the rock garden, as this would give better promise of more sunlight for Nymphaeas, and the better class of flowering bog and water plants. The pool and channel should be excavated to rather more than the required depth, and have a lining of cement or clay; the edges of the pool should be shelved, on which soil is placed before the water is introduced. Marsh and bog plants will then succeed around the margins, and in the water the better class of aquatic plants will find suitable conditions. Some stone may be added to the water area, and so make the transition from rock to water garden less abrupt.—T. S.

ROCK GARDEN: MANAGEMENT OF.

When the rock garden has been made the work is not over. It has to be "managed" also, otherwise it will soon be smothered and the more delicate plants either entirely killed or completely spoilt. This management of the rock garden is of such importance that we feel we must devote an article to it.

Suitable Soil.—Our first consideration must be the supplying of suitable soil to the pockets which are to contain the various plants.

Undoubtedly a light loamy soil is

suitable for a great number of rock plants. Generally speaking, the more gritty it is the better. This grit is supplied by crushed limestone or granite, and the limestone is greatly to be preferred. There are, however, some exceptions, notably two or three Dianthi, Ranunculi, Silenes, Drabas, and *Campanula alpestris*, with *Saponaria lutea*, which dislike lime in any form, and for these granite grit is the right material to use. The amount of grit varies with plants. Some of the smaller Androsaces, etc., like about one-fourth or more of the compost to be grit, while others, such as the stronger tall-growing Saxifrages, do wonderfully well in ordinary loam with little or no grit in it.

Of the rock plants which like a peaty soil probably the most notable are the Gentians. Most of the rock garden Primulas also like it, several of the Campanulas, Lithospermums, Daphnes, and a number of others too numerous to mention. Large works have been published on Rock Gardening, and doubtless readers will find complete details of plants which are peat lovers in them.

Site for Plants.—After getting a suitable soil the next thing to do is to choose a suitable site. It is, for instance, little use planting *Primula bulleyana* on a high and dry ridge, as it would certainly die, so fond is it of water ; nor is it at all desirable to plant any of the choicer Saxifrages, Sedums, and Sempervivums in damp, boggy holes, for they would soon perish. It is equally undesirable to plant the pretty *Oxalis enneaphylla* or *Primula pulverulenta* in the hottest, sunniest spots of the rock garden or to plant Dianthi or Silenes in the densest shade. Readers desirous of finding out the best sites should pay a visit to the Royal Gardens, Kew, the R.H.S. Gardens at Wisley, or the St. John's College Gardens, Oxford. There they will be able to study every variety of rock plant and see it in its best site. Naturally, to give a complete list here would be impossible.

Rock plants which need much moisture include the following, among hosts of others : Orchis, Ourisia, Primulas, *Ranunculus aconitifolius*, and *Saxifraga aizoides*.

Planting Out.—Above all things, rock-plants should be set in their positions firmly. The idea that they will grow if just popped in anyhow is absolutely absurd, and this loose planting is responsible for more losses than is anything else. In the case of planting in definite pockets, a hole should be taken out with a trowel and the plant put in (not deeper than it was originally set), so that there can be no possible hollow beneath its base. The soil all round it should be made very firm ; this will encourage the formation of new roots.

In the case of planting in clefts between rocks extra care is needed to see that there is no hollow for air beneath the plant's roots. The cavity is first filled with moderately fine, gritty soil, this being rammed in so as to fill it completely. Then a little is scraped out, the tiny plant put in, some soil being pushed in after it, and then its position is fastened by inserting a small angular stone to wedge it. Needless to say, planting ought never to be done in very dry nor in very wet weather. In the first case, the plants cannot get established through lack of the needful amount of moisture, and in the second, the soil is apt to cake when pressed hard, and so becomes too stiff for the formation of new roots. We think that all rock plants should be labelled, so that there is no doubt as to what they are.

Weeding of the Rock Garden.—Even in the first year after the making of the rock garden other things, namely, weeds, will start a-growing in it. We consider that it is advisable never to let the weeds "get ahead." If the rock garden once gets really weedy an enormous amount of labour will have to be bestowed upon it. The alternative is to have a regular round of the rock garden about once a fortnight, pulling up every weed showing then. This does not take long. Half an hour will see it done in the case of a small rock garden, and even if the garden be one of fair size about an hour will see the work through. One hour per fortnight is not much, and it will save days and days of work later.

Weeding, if done at all, should be done carefully, for if it be carelessly done choice plants may be irrecoverably injured. An old kitchen fork makes an almost ideal tool for weeding in the rock garden. A small basket should always be slung on your arm as you weed, otherwise little heaps of weeds are apt to get forgotten. It is a great mistake to leave small weeds in as being too small to do any harm. By the end of the fortnight they may have grown large and seeded; then you will wish you had not despised them, and had taken them out.

Trimming and Clearing Up.—After they have flowered there is hardly a rock plant which is not benefited by being trimmed up. All the dead flowers should first of all be clipped off, and then long straggly shoots trimmed back. Some rock plants, notably *Arabis albida*, *Alyssum saxatile*, *Aubrietia deltoidea*, and *Cerastium tomentosum*, require severe treatment in this direction, otherwise they overrun the rock garden, spoiling themselves and smothering other choice subjects. It is a good plan to keep plants such as the Ajuga and Cerastium away from extra choice plants altogether, for the roots of these two plants penetrate some distance and rob other plants of food.

At the end of the autumn there should be a general clearing up. All fallen leaves, decayed leaves of plants, dead flowers, and weeds should be most carefully removed, and the plants mulched with grit or light loamy soil. Labels should, if necessary, be renewed. Loose stones should be reset, dead plants renewed, and the whole rock garden made spick and span for the winter. Plants such as the Androsaces, the smaller and less hardy Sedums, Saxifrages, and Sempervivums, should be covered with a small piece of glass during the winter, otherwise they will die.

Propagation of rock plants is dealt with in separate articles. The same general rules in this or in any other form of propagation hold good. Rock plants can also be raised by sowing seeds on the surface of pockets of fine soil in the spring, the seedlings being pricked off and planted out elsewhere when large enough to handle. This is fully discussed in the article *Rock Plants from Seeds*.—E. T. E.

ROCK GARDEN SHRUBS.

Whether the rock garden be large or small, space should certainly be found for a few shrubs. The number suitable for the purpose is extensive, and affords, by the diversity of the various subjects, scope for very effective planning. Some appeal by the beauty of their flowers, others by their foliage, and others have the additional recommendation of bright-coloured berries, often at a time when flowers are altogether absent. They range from a few inches to several feet in

height, and include some of prostrate habit, which are invaluable for rambling over stones and down rocky slopes; others which form spreading bushes; and yet others of compact, upright growth. Their cultivation presents little difficulty, most of them thriving in ordinary, well-drained soil, though, as with other plants, there are some which prefer peaty soil. In the following list, which is by no means exhaustive, those which need special treatment are indicated. The best of these bearing attractive flowers are referred to in our article on *Flowering Shrubs*, and in some cases the flowers are succeeded by pretty berries.

With reference to the heights given in brackets after the name, it should be remembered that in many instances it takes a considerable time for the plant to attain to these dimensions, and in some cases it can be kept to any desired height by pruning.

Abelia chinensis (height, 4–8 ft.).
Abies excelsa pumila (height, 1 ft.); *A. e. pygmaea* (height, 1 ft.).
Acer palmatum in variety (height, 3–20 ft.).
Amygdalus nana (height 3–4 ft.).
Andromeda in variety [1] (height, 1 ft.).
Arctostaphylos Uva-ursi,[1] trailer.
Astragalus Tragacantha (height, 1 ft.).
Azalea Hinodigiri,[1] and *A. mollis*[1] *in* variety (height, 1–4 ft.).
Berberis in variety (height, 1–12 ft.).
Bruckenthalia spiculifolia[1] (height, 6–9 ft.).
Bryanthus empetriformis[1] (height, 1 ft.).
Buddleia variabilis prostrata, trailer.
Caryopteris Mastacanthus (height, 2–3 ft.).
Cassinia fulvida (height, 2–3 ft.).
Cistus, all varieties which like hot, dry positions (height, 2–4 ft.).
Cornus canadensis[2] (height, 6 ft.).
Corokea Cotoneaster, twisted branches (height, 2–10 ft.).
Cotoneaster horizontalis, prostrate (height, 2 ft.); *C. microphylla* (height, 4 ft.); *C. thymifolia* (height, 1 ft.).
Cydonia japonica, *C. Maule* (height, 3 ft.).
Cytisus Ardoini (height, 6–9 ins.); *C. decumbens*, prostrate (height, 6 ins.); *C. kewensis*, prostrate; *C. purpureus*, prostrate.
Daphne blagayana, trailer (height, 6–9 ins.); *D. Cneorum* (height, 1 ft.); *D. rupestris* (height, 2–9 ins.).
Erica carnea,[1] *E. c. alba*[1] (height, 6 ins.); *E. mediterranea hybrida*[1] (height, 1–2 ft.).
Erinacea pungens (Syn. *Anthyllis Erinacea* (height, 9 ins.).
Fabiana imbricata[1] (height, 2 ft.).
Gaultheria procumbens[1] (height, 6 ins.).
Genista andreana prostrata, trailer; *G. dalmatica* (height, 2–3 ft.); *G. humifusa*, *G. pilosa*, trailer (height, 2 ft.); *G. praecox* (height, 4 ft.); *G. tinctoria fl. pl.* (height, 2 ft.).
Hedera Helix conglomerata, non-climbing dwarf Ivy.
Helianthemum in variety (height, 9–24 ins.).
Juniperus communis aurea (height, 2 ft.); *J. c. hibernica compressa* (height, 6 ins.); *J. Sabina tamariscifolia* (height, 1–2 ft.).
Lavender Munstead Dwarf (height, 1 ft.).
Ledum palustre[1] (height, 1–1½ ft.).
Menziesia (Daboëcia) *polifolia*[1] (height, 2 ft.).
Olearia Haastii (height, 3–4 ft.).
Ozothamnus rosmarinifolius (height, 1 ft.).
Pernettya mucronata[1] in variety (height, 1½–2 ft.).
Perovskia atriplicifolia (height, 3 ft.).
Pinus aristata (height, 1 ft., though it eventually reaches 40 ft.).
P. sylvestris globosa[1] (height, 1–3 ft., but eventually reaches 80–100 ft.).
Potentilla fruticosa (height, 2–3 ft.).
Retinospora (Cupressus) *filicoides* (height, 1–4 ft.); *R. obtusa nana* (height, 1–4 ft.); *R. plumosa aurea* (height, 1–2 ft.).
Rhododendron ferrugineum (height, 1–2 ft.); *R. praecox* (height, 1–2 ft.); *R. racemosum*[1] (height, 1–2 ft.).
Rhodothamnus Chamaecistus (height, 9–12 ins.).
Salix sericea pendula, prostrate.
Santolina Chamaecyparissus (height, 12–18 ins.).
Spartium junceum (height, 6 ft.).
Taxus baccata Dovastoni pendula (height, 2 ft.).
Thuya occidentalis Spaethii (height, 2–3 ft.).

[1] A peaty soil is required by these, or at any rate one free from lime.
[2] This likes a shady site and peaty soil.

Veronica in variety (height, 6–18 ins.).
Viburnum Opulus nanum (height, 18 ins.).
Zenobia speciosa[1] (height, 1½–2½ ft.).

ROCK PLANTS: DISEASES OF.—See *DISEASES OF ROCK PLANTS*.

ROCK PLANTS DISLIKING LIME.—See *LIME-HATERS*.

ROCK PLANTS FOR ALL PURPOSES.—With so vast a number of subjects suitable for the rock garden, it is not surprising that marked differences are to be observed in their requirements and habits, and these differences afford opportunity for the flower-lover to make choice of those plants that are likely to accommodate themselves to the prevailing conditions in his garden, or, on the other hand, enable him to secure a wide diversity by providing for the individual predilections of each sort. Thus he may have plants that flourish in sun or in shade, in sharply drained or in constantly moist soil; in peat or in loam, or in the moraine; and though the majority flower in spring, when the rock garden is at its best, it is possible also to have a bright display in the summer and autumn. Furthermore, many of the plants are amenable to culture under glass, either in pots or on the indoor rockery, in which case they are usually earlier, and of purer and brighter colours. The cultivation of rock plants is dealt with elsewhere in this volume: the lists following indicate some of the principal subjects, and the purposes for which they are best adapted. There are, of course, many species and varieties not here enumerated, and additions to the number are constantly being introduced.

Rock Plants for Autumn Blooming.—The following are among the best:—

Acaena microphylla (dwarf creeper).
Androsace lanuginosa (height, 4 ins.).
Astilbe simplicifolia (height, 6 ins.).
Aubrietia in variety (height, 3–6 ins.
Callirhoë involucrata (height, 6 ins.); *C. lineariloba*, trailing (height, 9 ins.).
Campanula portenschlagiana (height, 9 ins.); *C. pulla* (height, 3 ins.); *C. pusilla* (height, 4 ins.); *C. Profusion* (height, 6 ins.).
Ceratostigma plumbaginoides (height, 6–9 ins.).
Coreopsis rosea (height, 12 ins.).
Coronilla cappadocica (trailing); *C. varia* (trailing).
Cyananthus lobatus (height, 3 ins.).
Cyclamen cilicium (height, 4 ins.); *C. europaeum* (height, 3 ins.); *C. neapolitanum* (height, 4 ins.); *C. n. album* (height, 4 ins.).
Dianthus Greipsii (height, 2 ins.); *D. neglectus* (height, 3 ins.).
Epilobium obcordatum, trailing (height, 3 ins.).
Erigeron mucronatus (height, 3 ins.).
Fragaria indica, trailing (height, 6 ins.).
Gentiana asclepiadea (height, 18 ins.).
Geranium in variety (height, 6–24 ins.).
Geum Heldreichii and varieties (height, 9–18 ins.).
Gypsophila cerastoides (height, 4 ins.).
Horminum pyrenaicum and varieties (height, 9–12 ins.).
Hypericum Coris (height, 9 ins.); *H. repens* (height, 4–6 ins.).
Inula ensifolia (height, 9 ins.).
Linaria alpina (height, 6 ins.); *L. Cymbalaria*, creeper (height, 2 ins.); *L. pallida*, creeper (height, 4 ins.).
Lithospermum prostratum (height, 4 ins.); *L. p. Heavenly Blue* (height, 4 ins.).
Lysimachia Henryi (height, 6 ins.).
Nepeta Mussini (height, 12 ins.).
Nierembergia rivularis (height, 3 ins.).
Œnothera caespitosa (height, 6 ins.); *Œ. missouriensis*, trailer (height, 6 ins.).
Omphalodes Luciliae (height, 6 ins.).
Onosma echioides (height, 9 ins.).
Plumbago Larpentae (Syn. *Ceratostigma plumbaginoides*) (height, 12 ins.).
Polygonum affine (Syn. *P. Brunonis*) (height, 6 ins.); *P. vaccinifolium*, trailer (height, 6 ins.).

Potentilla ambigua (height, 4 ins.); *P. nepalensis* (height, 18 ins.); *P. nitida* (height, 6 ins.).
Saxifraga Fortunei (height, 12 ins.).
Sedum Ewersii (height, 4–6 ins.); *S. E. turkestanicum* (height, 4 ins.); *S. populifolium* (height, 12 ins.); *S. spectabile* and varieties (height, 12–18 ins.).
Silene maritima and varieties (height, 4 ins.); *S. Schafta* (height, 4 ins.).
Statice bellidifolia (height, 4 ins.).
Teucrium Chamaedrys (height, 12 ins.).
Thymus carnosus (height, 9 ins.).
Verbena venosa (height, 9 ins.).
Zauschneria californica (height, 12 ins.).

Rock Plants for Bog and Water Gardens.—Any of the dwarfer and more compact subjects mentioned in our article on *Water Garden: Plants for the*, may be used successfully for these two purposes.

Rock Plants for Carpeting.—It is sometimes desired to lay a regular carpet in certain parts of the rock garden, and obviously attractive plants are best for this purpose. Of these we recommend the following: *Acaena microphylla, Ajuga reptans, Alyssum serpyllifolium, Antennaria dioica, A. d. hyperborea, A. tomentosa; Arenaria balearica, Cotula dioica, C. squalida; Frankenia laevis, Helxine Solierolii* (likes damp, and is of doubtful hardiness); *Herniaria glabra, Hutchinsia alpina, Hypericum humifusum, Linaria aequitriloba, L. pallida; Lithospermum prostratum, Lysimachia Nummularia*, and its golden-leaved variety; *Mentha Requieni, Mimulus radicans, Nertera depressa* (hardy only in the south, and requiring protection from snow); *Nierembergia rivularis, Prunella grandiflora, Sagina glabra, S. g. pilifera aurea;* Saxifrages of the mossy section, *S. oppositifolia* and others; *Sedum acre, S. anglicum, S. hispanicum, S. mawеanum, S. spathulifolium; Sibthorpia europaea, Thymus Serpyllum, Veronica canescens, V. repens*, and *V. Stuarti*.

Rock Plants for Cutting.—We were recently asked to give a selection of suitable rock plants for this purpose. As a matter of fact, suitable subjects are not numerous, but we recommend the following, the heights of which are approximate only, much depending on the treatment:—

Achillea serbica (height, 12 ins.).
Æthionema grandiflorum (height, 12 ins.).
Anthemis biebersteiniana (height, 12 ins.)
Aquilegia caerulea (height, 18 ins.); *A. canadensis* (height, 18 ins.).
Armeria latifolia (height, 18 ins.).
Cheiranthus Allionii (height, 12 ins.); *C. alpinus* (height, 12 ins.).
Cypripedium Calceolus (height, 6–12 ins.).
Erigeron alpinus (height, 12 ins.).
Erysimum in variety (height, 9–12 ins.).
Gerbera Jamesoni[1] (height, 12–18 ins.).
Geum montanum aurantiacum (height, 9–12 ins.).
Heuchera in variety (height, 12–24 ins.).
Iberis correaefolia (height, 9–12 ins.); *I. gibraltarica* (height, 12 ins.).
Macrotomia echioides (height, 12 ins.).
Phlox divaricata (height, 12–18 ins.).
Saxifraga umbrosa (height, 12 ins.).

Many of these plants are equally suitable for cultivation in the border; indeed, if required for cutting they should certainly be grown there, so as not to spoil the effectiveness of the rockery.

Rock Plants for Edging.—Any of the hardier and less aggressive though strong-growing subjects are suitable for this purpose. For selection see article on *Edging: Hardy Plants for*.

Rock Plants for Half-shade.—The requirements of most of these plants can be met by giving them a position where they are not exposed to full sun at midday. In the case of the dwarfer subjects a stone on their south side will suffice. The following are the chief: *Adonis vernalis, Androsace arachnoidea,*

[1] Protect in winter.

A. carnea, A. Laggeri, A. pyrenaica; Aquilegia caerulea, A. canadensis; Aster alpinus, Campanula pulla, C. pulloides, C. pusilla; Ceratostigma plumbaginoides (Syn. *Plumbago Larpentae*); *Cotyledon chrysanthus,* Cyclamen (hardy species); *Cypripedium Calceolus,* Dryas in variety, *Epigaea repens, Erodium chamaedryoides,* Globularia in variety, *Linnaea borealis, L. canadensis;* Mertensia in variety, Omphalodes in variety; *Ourisia coccinea,* Polygala in variety, Primula in variety (except *P. Balbisii, P. frondosa, P. marginata,* and *P. suffrutescens*); *Rubus arcticus,* Saxifraga, the mossy section, *S. brunoniana, S. erosa, S. Fortunei, S. Geum, S. granulata, S. lilacina, S. mutata, S. nivalis, S. retusa, S. squarrosa, S. Sternbergii, S. Wallacei;* Shortia in variety, Soldanella in variety, *Tanakaea radicans,* and *Viola pedata.*

Rock Plants for Indoor Culture.—Certain of the prettiest rock plants are not hardy in this country, and require the protection of a cold or slightly heated greenhouse in the winter. The chief of these are listed in our article on the *Alpine House.*

Rock Plants for Moraines.—The best subjects for this purpose are given in our article on *Moraine Gardening,* which see.

Rock Plants for Paved Paths.—Paved paths and the chinks between stone steps, are often unnecessarily bare, whereas they may be planted with dwarf-growing subjects, which greatly enhance the beauty of the garden as a whole. Among plants suitable for this purpose are the following: Acaena in variety, *Achillea tomentosa, Alyssum montanum, Antennaria dioica, Armeria maritima,* Aubrietia in variety, *Calamintha alpina, Campanula muralis, C. pulloides, C. pusilla; Cerastium tomentosum, Cotula dioica, C. squalida; Dianthus deltoides, Draba pyrenaica, Erinus alpinus, Erythraea Massoni* (Syn. *E. diffusa*); *Frankenia laevis, Linaria aequitriloba, L. Cymbalaria; Mentha Requieni, Oxalis corniculata,* Ruta in variety, *Thymus lanuginosus, T. Serpyllum* and its variety *splendens.*

Rock Plants for Rocky Crevices.—Many of the most beautiful rock plants require a cool, moist root-run, while they are impatient of wet about their crowns and on the foliage, especially in winter. The best position for them is in a crevice between stones, where their roots can find the moisture they love, while the rain is thrown off from the crowns. Those with hairy leaves are also benefited by having a piece of glass fixed above them in winter, so that air can circulate freely about them while they are protected from excessive wet. Of these the following are the chief: Acantholimon in variety, Æthionema in variety, Androsace in variety, *Arabis androsacea, Campanula hirsuta, C. tommasiniana, C. waldsteiniana;* Cerastium in variety, *Cortusa Matthioli, Dianthus alpinus, D. a. Atkinsonii, D. caesius, D. Freynii, D. glacialis, D. neglectus, D. nitidus, D. sylvestris;* Draba in variety, *Erigeron mucronatus, Eritrichium nanum, Hypericum tomentosum, Leontopodium alpinum, Lewisia rediviva, Lychnis alpina,* Mertensia in variety, Morina in variety, Noccaea in variety, Onosma in variety, Origanum in variety, *Phyteuma comosum, Primula Allionii, P. Auricula, P. auriculata, P. Balbisii, P. ciliata, P. clusiana, P. hirsuta, P. integrifolia, P. marginata, P. villosa, P. viscosa; Saponaria caespitosa, S. lutea;* Saxifrages of the encrusted section, also *S. Boydii, S. burseriana, S. caesia, S. Elizabethae, S. Grisebachii, S. liliacina, S. marginata, S. rocheliana, S.*

Salomoni, S. tombeanensis, S. valdensis; Sedum in variety, Sempervivum in variety, *Teucrium Polium,* Tunica in variety, and Wahlenbergia in variety.

Rock Plants for Shade.—*Androsace foliosa, Arenaria balearica, Cathcartia villosa, Chrysogonum virginianum, Claytonia asarifolia, C. caroliniana, C. sibirica; Cortusa Matthioli, Cyananthus lobatus;* Dodecatheon in variety, *Eomecon chionantha, Galax aphylla, Haberlea rhodopensis, Hacquetia Epipactis,* Houstonia in variety, *Isopyrum thalictroides, Mitchella repens, Primula Allionii, P. calcycina, P. cortusoides, P. decorum, P. latifolia, P. megasaefolia, P. pubescens alba, P. villosa;* Pulmonaria in variety, Ramondia in variety, and Wulfenia in variety.

In addition to these, Ferns will supply a wealth of interesting species and varieties.

Rock Plants for Spring Blooming.—More rock plants bloom in the spring than at any other time of the year, and to give a complete list would require many columns, and these cannot be spared. Attention is therefore drawn instead to the plants which bloom at the other three seasons of the year, when, as a rule, rock garden flowers are scarce, in order that readers may know what to plant to give a succession of bloom.

Rock Plants for Summer Blooming. — Acantholimon in variety, Æthionema in variety, *Aster alpinus, Astragalus danicus,* Calamintha in variety, *Campanula Allionii, C. carpatica, C. pulla, C. pusilla, C. Raineri, C. tommasiniana, C. waldsteiniana; Cathcartia villosa, Cerastium tomentosum, Claytonia caroliniana, Conandron ramondioides, Corydalis thalictrifolia, Cyananthus lobatus, Cyclamen libanoticum, Dianthus cruentus, D. Freynii, D. Napoleon III., D. neglectus;* Dryas in variety, *Erigeron mucronatus, Erinus alpinus,* Erodium in variety, *Galax aphylla. Gentiana Andrewsii, G. asclepiadea, G. septemfida;* Geranium in variety; *Geum Borisii, G. Heldreichii; Gypsophila repens, Haberlea rhodopensis,* Helianthemum in variety, Heuchera in variety, Jasione in variety, Linum in variety, *Nepeta Mussini, Nierembergia rivularis, Omphalodes Luciliae, Phlox procumbens, Platycodon grandiflorum, Polygonum affine, Potentilla Gibson's Scarlet, P. Miss Willmott; Prunella webbiana, Saxifraga Fortunei, Scutellaria alpina, Sedum acre, S. Anacampseros, S. Ewersii, S. obtusatum, S. populifolium, S. pulchellum, S. rupestre, S. Sieboldii, S. ternatum; Silene maritima, S. Schafta; Teucrium Chamaedrys, T. Marum; Thymus Serpyllum, Verbena venosa, Veronica Bidwillii, V. caespitosa, V. incana;* and *Wahlenbergia Kitaibelii.*

Rock Plants for Sunny Sites.—As by far the greater majority of rock plants succeed best in the sunniest possible site, this should form a guide to their successful culture. It may justly be assumed that if the plants are not in the lists for shade and half-shade a site in full sun is necessary for them, and to give the hundreds of such subjects would be unnecessary waste of space.

Rock Plants for Winter Blooming.—Of rock plants proper it cannot be said that there are any which bloom out of doors in winter, but many of the Saxifrages come early when the season and general conditions are favourable. In sheltered nooks at the foot of the rockery the Christmas Rose will not belie its name, and the fragrant blooms of *Iris alata, I. reticulata,* and others will open in February, while those of *I. unguicularis* may be had from November onwards. But the Irises suggest

bulbs, and of these there are fortunately a goodly number which may be employed. (See article on *Rock Garden Bulbs*.) Of course, on the rockery under glass, and in the *Alpine House* (see separate article), it is not difficult to produce a charming display throughout the winter.

Rock Plants Disliking Damp.—The rains of winter injuriously affect many rock plants, which can endure frost unharmed, and which must have air around them at all times. A piece of glass elevated a few inches above them in winter will assist to throw off the superabundant moisture, and bring them safely through the winter. Among those recommended for this treatment are the following: Æthionema, Androsace, *Antirrhinum Asarina, A. sempervirens; Arabis androsacea, Artemisia lanata, Asperula suberosa, Campanula hirsuta, Cerastium alpinum lanatum, Corydalis Wilsoni,* Dianthus of tufty habit, Draba, *Eritrichium nanum, Helichrysum arenarium, Hieracium villosum,* Houstonia, *Hypericum Coris, H. tomentosum; Leontopodium alpinum, Lewisia rediviva, Lychnis alpina,* Meconopsis, Onosma, *Papaver alpinum, Potentilla villosa,* encrusted Saxifrages, *Teucrium Polium,* Wahlenbergia, and *Zauschneria californica.*

With some of these plants it is sufficient if they are planted on their sides wedged between stones, so that water cannot lodge around their leaves in winter. This is true of the encrusted Saxifrages, and also applies to those which form cushions, and to other dwarf plants with silky or downy leaves.

Rock Plants Disliking Lime.—The chief of these are included with other similar subjects in our article on *Lime-Haters*.

Rock Plants of Rampant Growth.—Where the rock garden is small, and space is limited, it is obvious that plants of very rampant growth are likely to encroach upon their neighbours, and to smother the choicer and slower-growing or stay-at-home subjects. Many, of course, can be kept in check by constant watchfulness, cutting back straggling shoots as they appear; others, which spread by means of underground stems, are not so easily dealt with. They have their good points, and are often of great decorative value; therefore, their inclusion or rejection is a matter for individual judgment. Among rampant growers are the following: Achillea in variety, *Alyssum saxatile, Arabis albida,* and its double variety; Aubrietia in variety, *Centranthus ruber, Cerastium Biebersteinii, C. tomentosum; Coronilla varia, Dryas octopetala, Epilobium nummularifolium, E. obcordatum; Fragaria indica, Gypsophila repens, Hypericum repens, H. reptans; Linaria Cymbalaria* and varieties, *L. pallida; Lithospermum prostratum, L. purpureo-coeruleum; Lotus corniculatus fl. pl., Lysimachia Nummularia, Nepeta Glechoma, Omphalodes verna, Oxalis Acetosella, O. corniculata* (annual, which sows itself very freely); *Prunella grandiflora, Rubus arcticus, Saponaria ocymoides, Saxifraga trifurcata* and other mossy Saxifrages, *S. umbrosa; Sedum acre, Silene maritima, Thymus Serpyllum,* and *Waldsteinia fragarioides.*

Rock Plants Requiring Peat.—Androsace in variety (except *A. lactea, A. obtusifolia,* and *A. villosa*); *Cathcartia villosa,* Claytonia in variety, *Conandron ramondioides, CortusaMatthioli, Cyananthus lobatus, Epigaea repens, Galax aphylla, Gaultheria procumbens, Haberlea rhodopensis,* Houstonia in variety, *Linnaea borealis,* Mertensia in variety, *Mitchella repens,* Polygala in variety, *Primula farinosa, P.*

floribunda, P. integrifolia. P. intermedia, P. involucrata, P. longiflora, P. minima, P. Portae, P. rosea, P. sikkimensis; Ramondia in variety, *Rubus arcticus,* Shortia in variety—sandy peat and loam or leaf-mould; Soldanella in variety, *Tanakaea radicans,* and Wulfenia in variety.

ROCK PLANTS FOR SHADE and ROCK PLANTS FOR SUNNY SITES. See *ROCK PLANTS FOR ALL PURPOSES.*

ROCK PLANTS FROM SEEDS.

This, we think, is undoubedly the cheapest and most interesting way of raising rock plants and stocking an extensive rock garden, but it also means that a far longer period must elapse before that garden is replete with and blooming fully with the choicest and best of plants. It has been said that the raising of rock plants from seed is a far more suitable task for the hardy alpine plant specialist than for the ordinary gardener: that may be, but there is no reason at all why the ordinary gardener should not try his hand at this interesting undertaking as well as his specialist brother.

Starting. — If we view the subject generally before starting we find it is full of controversial details. Some authorities say that the seeds should be sown in heat: others that artificial heat is not only unnecessary but very detrimental. Some say that the seed should be sown as soon as it is ripe: we think this point is not important. Yet others say that the soil should be baked in the oven for a lengthy period before sowing the seed, and others, including ourselves, think that this is not at all important. Still others say that rock plants should be sown in a compost nine-tenths of which is grit, and on the contrary other gardeners are of the opinion that such an excessively gritty compost is undesirable.

Sowing the Seed. — Sweeping aside the maze of controversial details we will give our own views on this important and interesting subject. We prefer to sow the seed of rock plants either in very gentle heat in February, or in a cold frame in early March. Shallow boxes or pots are undoubtedly preferable for the purpose instead of sowing the seed directly on to the frame soil-bed. Plenty of drainage of crocks of all sizes is first of all put into the pots or boxes: this is then covered with a little rough compost and filled up to half an inch from the rim with soil passed through an eighth-inch sieve. We do not consider sterilising the soil to be the least necessary provided that old two-year-rotted meadow loam, three-year-old leaf-mould, and clean sharp silver sand—not road sand—are used for the compost. If the soil be sterilised, much of the useful vegetable matter in it which goes so far to producing sturdy plants is lost, and only useless mineral matter remains. This is, of course, our personal view. Other authorities strongly urge that the soil be sterilised to kill weeds and pests, but if old material be used these last should not be abundant. From one-eighth to one-fourth of the compost should be sand according to the natural habitat of the plants. Moraine plants, for instance, require a great deal of grit to germinate satisfactorily, whereas the stronger "meadow" blooming rock plants can do with very little. When the

pots or boxes are ready they should be well watered, and then the seed sown upon them very thinly. Seed varies in size, and the usual method of sowing small seed of any kind, namely the mixing of it with ten times its own volume of sand, should be adopted. A firm seed-bed is desirable. If the seed is exceedingly delicate and chary of germination, a layer of sand should be spread over the surface of the soil, as is done in the case of Mimulus, Nemesia, and other small seeds of greenhouse subjects. The seed is then very lightly covered with soil, the pans being covered with brown paper and glass without further watering.

As soon as there is any sign of germination the glass and paper must be removed, and the boxes inured to the light. Watering overhead is apt to be very dangerous, and it is far better to immerse the pots or boxes in tubs of warm soft water till the soil is well moistened. The boxes, etc., should be put close to the glass, and very great care taken to give them plenty of air at all times.

Pricking Off. — When large enough to handle conveniently and before there is the slightest chance of them becoming crowded, the seedlings should be pricked off. We prefer to prick them off into a cold frame and let them remain there for a few months keeping them well watered, rather than put them into pots straight away. The surface of the bed should be freely scattered with limestone chippings, or with granite fragments in the few cases where plants do not like lime. Firm planting is advisable. A distance of 5 ins. from plant to plant is ample. During the hot summer weather, watering and shading are essential.

In September or early October the plants may be lifted and transferred to small pots of similar light sandy compost with plenty of drainage. Firm potting is desirable. The surface of the pots can have grit or chips thrown on it to tend to keep it sweet. Give a good watering after potting, and immediately plunge the pots up to their rims in cinder or coke ashes in a frame. Ventilate freely on fine days but protect from frost. They can be planted out the following spring and will flower later on, but it is best to clip the flowers off in order to conserve the strength for free blooming next year.—E. T. E.

ROCK SPRAY.—See the genus COTONEASTER in *SHRUBS.*

ROCK WALLS.— These are referred to in the Editorial Note to our article on *GARDEN WALLS.*

ROCKERIES.

These differ from rock gardens in size and character. Rock gardens are usually large, rockeries small; and, again, rock gardens when properly made always look natural and artistic, while rockeries, however well made they may be, always look quite unnatural and inartistic. There is usually a definite *raison d'être* for a rockery, such as a bank to be supported or an ugly empty corner to be filled, but there is nothing of the

kind, or should not be, in the case of a rock garden.

As there is this definite purpose of rockeries, some of the rules of rock garden making may be broken. Stones may be perched end upwards so long as they hold up earth, and no regard need be paid to the bedding marks on the stones. As a rule the stronger-growing rock garden subjects, such as Ajuga, Alyssum, Arabis, Aubrietia, Cerastium, Lithospermum, etc., are the most suitable for rockeries, though they require severely cutting back after flowering to keep them within bounds.

ROCKET (*Hesperis*. DAME'S VIOLET. Nat. Ord. Cruciferæ).—This is a plant highly prized by lovers of the more old-fashioned flowers, and also by modern gardeners who delight in perfumed flowers. Most of the species have a very sweet scent, emanating more especially at night, and a lengthy blooming period. The annual species are omitted as they are hardly worth growing, but species which are biennial will be found described elsewhere in this work, in our notes on *NIGHT-SCENTED STOCK*.

The hardy perennials, which concern us in the present article, are of the easiest cultivation, thriving in ordinary light soil of good quality in a sunny or very lightly shaded site. They are grand for the perennial, herbaceous, or mixed borders and may be used effectively at the back of rock borders to surprise new-comers with scent, which is as a rule scarce in that portion of the garden. Some, especially *H. matronalis*, are splendid flowers for cutting. Propagation may be effected by seeds sown in the usual way in the spring or summer, but the best way is to divide the roots, not in October, November, or March as is usually done (though at times this is quite satisfactory), but to split them up in July and August, keeping them for a few months in the reserve garden after doing this if possible. In the case of the double sorts, however, it is more satisfactory to insert cuttings in light soil about midsummer. Planting may be successfully done, as for all other hardy perennials, in the autumn or spring.

What to Grow.—We recommend the following, but only *H. matronalis* and *H. violacea* are in the *Kew Hand-list of Herbaceous Plants*:—

Hesperis aprica.—This is a pretty dwarf purplish May blooming sort only 6 ins. high.

H. elata.—Syn. *H. matronalis*, which see.

H. excelsa.—This is a delightful early blooming white sort flowering in May, and averaging 1–2 ft. high.

H. matronalis (Syn. *H. elata*).—This is quite the most popular and the best species of all. Nurserymen offer it in various colours, such as purple, pink, red, red-purple, and double white and red, but the type is a single purple. The best varieties include *alba* (single white); *alba plena* (double white); *lilacina plena* (pale double purple); *nana alba plena* (dwarf double white); and *purpurea plena* (dwarf double purple). The double forms are the most important and are grand for cutting. The OLD SCOTCH ROCKET is better than any of the above, but is now very rare. The above varieties and the type bloom freely from early June to late July, and grow about 1 yd. in height.

H. violacea.—This bears violet or blue-purple flowers in May and June, on plants about 1½ ft. high.

ROCKET CANDYTUFTS.—These have been produced from *Iberis umbellata*. See *CANDYTUFT*.

ROCKET LARKSPURS.—These have been produced from *Delphinium Ajacis*. See *LARKSPUR*.

ROCKFOIL.—A popular name for *SAXIFRAGA*, which see. It is also dealt with in *WATER GARDEN : PLANTS FOR THE*.

ROCKWOOD LILY (*RanunculusLyalli*). See note at end of *RANUNCULUS*.

ROCKWORK.

Rocks may be studied from several points of view. The petrologist determines the material of which they are composed; the geologist considers their mode of occurrence and origin, and their relations to one another in nature; while the architect and engineer put them to practical uses. From each of these groups of workers we can take some ideas that will be of use for our present purpose. From a practical point of view the engineer has to consider questions of weight, strength, porosity, and durability, all of which are of importance in connection with rockwork. In planning a rock garden we must, of course, first of all get some estimate of the amount (volume or weight) of material required. In their weight (or more strictly, specific gravity) rocks of different kinds vary between wide limits, but those more suitable for rockwork range from 120 to 180 lb. per cubic foot. With an average of 150 lb., a ton of stone therefore measures about 15 cubic ft., that is $5 \times 3 \times 1$ ft. or $3\frac{1}{3} \times 3 \times 1\frac{1}{2}$ ft. Figures relating to the crushing strength of different kinds of rocks need not be given here, for the practical gardener will readily see for himself whether any particular material is too soft or friable for use. But it must be borne in mind that certain rocks, for example, shales and shaly limestones, soon break down when exposed to the weather. A point of much more importance than may at first thought appear, is that of porosity. Hard or compact, non-porous rocks, such as granite, basalt, and quartzite, offer little hospitality to plants. On a smooth, polished surface of such rocks even the humblest plants, namely, lichens, cannot find a hold. On a porous rock, however, lichens and mosses insinuate themselves into the pores and crevices with considerable ease, and the same applies to the roots of rock plants. Again, porosity is of importance in enabling the stone to retain moisture. For example, a porous sandstone may absorb as much as 15 lb. of water per cubic foot, or, in other words, 1 ton of stone may hold about 2 cwt. of water, which will measure about $22\frac{1}{2}$ gallons.

We now will continue by giving a few particulars about the various kinds of rock and their uses :—

Limestone.—As is well known, plants may be broadly divided into three classes, namely, lime-lovers, lime-haters (see the article *LIME-HATERS*), and those which are indifferent to lime. It is also well known that virgin soils rich in lime are derived from limestone rocks; but it must be remembered that many other kinds of rocks also contain lime, although not always in a soluble form directly available as a plant food. In limestone the lime is present in the form of carbonate of lime, which is soluble to a slight extent in water containing carbonic acid gas (carbon dioxide). Since carbon dioxide is always present in rain-water, it follows that in the presence of limestone the soil-water carries dissolved lime. Limestone is thus the best material for rockwork when lime-loving plants are to be cultivated.

Rocks of this class vary enormously in their appearance and characters—ranging from white to black in colour, and from chalk to marble in their degree of compactness—in fact, a limestone can-

not always be recognised by mere inspection. It will therefore be useful to mention the following simple tests :—

All limestones can be readily scratched with a knife.

They do not scratch glass.

They effervesce briskly in contact with acid (dilute hydrochloric acid is the best to use).

Limestones are abundant in many parts of the country, and suitable material can often be obtained near at hand. The hard and compact *Mountain Limestone* abundant in the North of England is excellent material for rockwork, and there are several others belonging to other geological formations that are equally suitable. As a rule, those belonging to later geological periods (*e.g.* the *Oolites*) are softer and less compact, but suitable material may also be selected from these beds.

Two special kinds of limestone, useful for rockwork by reason of their porous or cellular structure, may be mentioned. *Travertine* is a grey or buff-coloured, more or less honeycomb-like rock, but at the same time is hard and durable. It is typically developed near Rome, and is used in the rock gardens of the Riviera. Similar material is quarried for rockwork at Dursley in Gloucestershire. *Dolomite* or Magnesian Limestone has sometimes much the same appearance as Mountain Limestone, but differs from it in containing magnesium carbonate in addition to calcium carbonate, and in effervescing only with warm acid. This rock is typically developed in the Dolomite mountains of the Tyrol, where a rich alpine flora flourishes, and it is abundant in the north-east of England.

Sandstone. — This ranks with limestone as a material of first importance for rockwork; and is, of course, more suitable for lime-hating plants. Rocks of this class consist of sand grains of the inert mineral quartz bound together by some cementing material, which may be clayey, limy, or irony in its nature. When the cement is calcareous the rock has the same effect on plants as a limestone. Sandstones vary greatly in their appearance and characters, and applying the tests mentioned above under limestone, it will be found that they scratch glass, and that only those with a calcareous cement will show a slight effervescence with acid. Sandstones are of wide distribution, being met with in all geological formations, and suitable material for rockwork can generally be found near at hand.

Coarse-grained sandstones are known as Grits (for example, the *Millstone Grit* of the North of England); and if pebbles are also present Grits become *Conglomerates*. Both are suitable for rockwork.

What to Avoid.—The very hard and compact granite is useful only when it is partially weathered and decomposed, it being then to some extent porous. Quarry waste from near the surface is thus more suitable for rockwork than good quarry stone extracted for building purposes. Slate Rock is usually too compact and fine grained, while the softer shales break up into flakes on exposure to the weather. Basalt also is very hard and compact, and the sombre black colour is scarcely pleasing. At the other extreme is the soft, white Alabaster of the Midlands, which, though often used for small rockeries, is scarcely a suitable material, and the same applies to the softer kinds of Chalk. Blocks of stone from the waste heaps of mines should also be avoided, or at least carefully selected. Here

iron pyrites and other metallic minerals may be present, if only in small amounts, and these are readily decomposed on exposure to the weather with the formation of free sulphuric acid and injurious metallic salts. Other materials to be shunned are tree stumps, fused bricks, slags, clinkers, and of course such oddments as pottery refuse, shells, coral, bits of spar, stalactites, etc.

Artificial Stone.—This can often be used with good effect, as seen in some of our London parks; but it should only be employed when natural stone is not available. It is made as concrete with Portland cement, and if suitable small pebbles can be incorporated the result will be hardly distinguishable from conglomerate or coarse grit. It is, however, necessary that the material should not be cast in sharply angular blocks.

On the arrangement of stones in rockwork, see the article *Rock Garden: Making a.*—L. J. S.

ROCKY CREVICES: Subjects for.—See Rock Plants for Rocky Crevices in *Rock Plants for All Purposes.*

ROCKY MOUNTAIN COLUMBINE (*Aquilegia caerulea*).—See *Aquilegia.*

ROCKY MOUNTAIN FIR (*Abies lasiocarpa*).—See *Trees.*

RODGERSIA (Nat. Ord. Saxifragaceæ).—Only two species of this genus figure in the second edition of the *Kew Hand-list of Herbaceous Plants.* These, *R. pinnata* and *R. podophylla,* bear rose-pink and white flowers respectively throughout July, and grow up to 1½ yds. in height. They are both useful subjects in perennial and mixed borders, and the second is specially handsome, but requires well staking. They may be grown in the ordinary way for hardy perennials in a sunny spot provided a moist peaty soil is afforded them, and they are easily propagated by seeds sown in the summer or by root division in February or March, during which months they are best planted. Two newer species introduced into general cultivation after the issue of the *Hand-list* are *R. aesculifolia* and *R. tabularis.* Both may be grown on the same lines as indicated above; both bear white flowers from July onwards; and both average about 1 yd. in height.

ROLLERS.—See Garden Rollers in *Garden Appliances.*

ROLLING LAWNS.—See *Lawns and their Management.*

ROMAN CHAMOMILE.—See under Chamomile in *Medicinal Herbs.*

ROMAN CYPRESS (*Cupressus sempervirens*).—See *Trees.*

ROMAN HYACINTHS and ROMAN AND ITALIAN HYACINTHS.—See *Hyacinth.*

ROMNEYA (Nat. Ord. Papaveraceæ).—Only two species of this are strictly herbaceous, and these in the more exposed northern and eastern districts cannot be said to be quite hardy, inasmuch as they require winter protection, otherwise they may be grown in the usual way for herbaceous perennials in the flower, shrub, or wild garden borders. Of the sorts of which we are now speaking, *R. Coulteri* bears white yellow-centred flowers from July to September, on plants 2–5 ft. in height, and *R. trichocalyx,* a newer species, is similar in its general characters, but is rather better.

See also *Shrubs.*

ROMULEA (Nat. Ord. Iridaceæ). This is a genus of hardy and half-hardy bulbs, requiring no special treatment beyond that usually bestowed on hardy and half-hardy plants. They prefer a sandy soil

rich in humus, and are easily propagated by offsets. The best HARDY sorts include *R. Bulbocodium* and *R. Columnae*, while HALF-HARDY sorts should be represented by *R. clusiana*, *R. Macowani*, *R. monadelpha*, and *R. rosea*. They mostly bear yellow and lilac flowers in May, and average 3–12 ins. high.

ROOF GARDENING.

With modern houses steeply roofed with slates or tiles very little roof gardening, if any, is possible. Nor do we recommend those living in old-fashioned houses to go in for it, as the plants are a good deal of trouble to manage, up above the world as they are. We think roof gardening is a thing of the past; certainly it has no future, and we consider it would be waste of space to give a list of suitable subjects.

ROOT ABSORPTION.— See *PLANT PHYSIOLOGY*.

ROOT CROPS.—See *KINDS OF CROPS*.

ROOT-PRUNING.

Many planters, especially the inexperienced, observe that their fruit trees begin to bear the first or second year after they are planted, but afterwards grow vigorously and become unfruitful. Experienced ones expect this, and act accordingly. The reason is that young trees make an immediate endeavour to attain something like their natural dimensions, after which they settle down to the business of life and bear more or less heavily according to their natural capabilities. The object of root-pruning is to reduce the excessive vigour of growth they acquire after being established for a few years, and restore them to a state of fruitfulness, within reasonable limits of space. The pruning back of the branches will not effect this, but will give rise to stronger growth in future years, owing to the great strength and development of the root system by comparison with the reduced top of the tree. Cordon, bush, and pyramidal trees, intended to be kept within restricted limits, and to bear well, require most frequent attention to root-pruning. Standards and half-standards should be given more room and allowed to grow naturally, till they reach bearing size and age; but even they require root-pruning occasionally, when the fertility and nature of the soil induce them to make much growth, or the roots get down into a wet or uncongenial subsoil.

How to Root-Prune.—In the case of trees three to six years old, the most expeditious method of root-pruning them is to lift and replant them in the same position, after cutting back the long straggling roots and those which penetrate the ground more or less perpendicularly. Use a sharp knife to make clean cuts, removing all damaged roots, but preserving all the fibrous ones possible. If the trees are too crowded the obvious course is to replant them more widely apart.

Trees seven to twelve or more years old should be root-pruned where they stand. Take out a trench 3–5 ft. from the bole of the tree, leaving an undisturbed circle, 6–10 ft. in diameter, so as not to endanger the stability of the tree during windy periods for the first year. Discretion should determine the width of the circle, according to the weight or spread of the head of the tree; but usually 6 ft., would be ample, except in the case of large standards. Light rather than severe root-pruning should receive due consideration. The trench should be sufficiently wide to allow for freedom in working, and sufficiently deep to enable the operator to excavate the soil from beneath the ball, in order to cut roots that go

down deeply All the strong roots that come into the trench should be cut; if too thick for a knife they should be cut with a saw, as well as those which penetrate the soil perpendicularly, and the cut ends smoothed with the knife. This completed, the soil should be replaced gradually beneath the tree, ramming it hard with a stick as the work proceeds, unless the feet can be used conveniently It is a good plan to fill in the upper part of the trench with a compost consisting of good loam, a little leaf-mould, some old mortar, broken finely, and a fair sprinkling of wood ashes. This should be trodden down quite firmly and covered with the remaining soil. The cut roots will ramify in this compost, producing plenty of fibres, which are conducive to early fruitfulness.

When standards and half-standards make a quantity of young wood, and fruit but sparingly, root-pruning will often correct them. Bear in mind, however, the weight of the head, especially if unduly exposed to wind, and determine the width of the circle, to be on the safe side. In the case of very large trees it is a good plan to root-prune only half of the tree the first year, and complete the work the following one. The wind will have least effect upon the tree if the circle is outlined, one-fourth of the trench dug on the north-east side, and the other fourth on the south-west side. This is the best plan, though the opposite directions would answer as well. The trees so operated upon should be marked or numbered, so that the two remaining portions may be completed the following autumn.

Wall trees are root-pruned on similar principles, the only difference being that the trench is taken out in the form of a half-circle at a proper distance from the trunk of the tree.

October is the best month for root-pruning generally, because the wood is ripened, the trees are going to rest, and the autumn rains have sufficiently moistened the soil to prevent the premature withering of the leaves. It is occasionally done during September in the cooler northern parts of the country, and may be done during November, if need be, but the middle course is best. The benefits of the operation will not make themselves felt the first year, but during the second, as the flower buds are formed in the autumn.—J. F.

ROOTERIES.

These are similar to *Rockeries* (see separate article), only tree roots are used instead of stones. They harbour a lot of insect pests, especially woodlice, and are not to be recommended. Any of the stronger-growing subjects named in the above-mentioned article are equally suitable for the present purpose, and look very well when the roots have been nearly covered.

ROOTS: Manures for.—See under Crop Requirements in *Manures*.

ROOTS OF PLANTS: Their Functions.

It seems to me that there are very few gardeners who realise what the true functions of the roots of plants are, hence it will be well to explain the matter in a few words.

Roots are not given plants merely as a means of holding the leaves and stems upright, but they are there to feed the plants. The roots are really mouths as well as limbs of plants—a fact not generally appreciated.

A foolish idea has got round that plants feed entirely through their leaves, and that the only function of the roots is to steady the plants in the ground and supply them with water. With some plants experiment has shown that this idea is true, but there are indeed very, very few plants in which this is the case. In most cases the roots act as a mouth, through which food dissolved in water passes, to be made with the carbon dioxide of the air into leaf, stem, and fruit.

Much more care ought to be taken than is taken to keep the soil in a suitable condition for the roots of plants to draw food from. If the soil is too wet, as well as acid and sour, the roots decay, and hence they are not able to perform their function of feeding the plants. That is why on such a soil our crops turn sickly and die; they cannot get enough food from it, and though the food may be present in quantity it is in an unsuitable form.

If the roots are to perform this function of drawing large quantities of food from the soil, more than the usual care should be taken in planting to spread them out properly. The usual haphazard method of sticking plants in anyhow with their roots all twisted, is far from good, and should never be followed by anyone who wants his plants really to thrive. Study of the nature of the roots of plants, though it may be so humble a pastime, is well worth doing, and will amply repay in success later on.—E.

ROSA.—See *ROSE*. See also under ROSE, FRENCH, in *MEDICINAL HERBS*.

ROSE (*Rosa*. Nat. Ord. Rosaceæ).

So important is this, the Queen of Flowers, that we do not feel able to do justice to it in a single article, and are thus devoting several to it. The classes and garden varieties are dealt with in our article on *ROSE CLASSES*; the chief diseases it is subject to are dealt with in our article on *ROSE DISEASES*; its chief pests will be found, with remedies, in the article on *INSECT PESTS*; planting forms the subject of a special article on *ROSE PLANTING*; pruning is dealt with in our notes on *PRUNING ROSES AND SHRUBS*; the best species are described in the article on *ROSE SPECIES*, while selections for some of the many purposes to which Roses may be applied are given in the article on *ROSES FOR ALL PURPOSES*.

ROSE ACACIA.—The genus ROBINIA and *R. hispida*. See *TREES*.

ROSE APHIDES, or GREEN AND RED FLY.—See *INSECT PESTS*.

ROSE BANKS.—See *BANKS*.

ROSE BAY (*Epilobium angustifolium*). — See *EPILOBIUM* and *WATER GARDEN: PLANTS FOR THE*.

ROSE-BUD CHERRY (*Prunus pendula*).—See *TREES*.

ROSE CAMPION (*Lychnis Flos-Jovis*). See *LYCHNIS*.

ROSE CANKER.—See *ROSE DISEASES*.

ROSE CLASSES.

Though the Hybrid Teas, Teas, Hybrid Perpetuals, and Pernetianas or Austrian Hybrids, with the Wichuraianas and multifloras, comprise the bulk of the Roses in general cultivation, there are several important classes which also provide varieties of great merit, and which find a place in many gardens. Botanists recognise a large number of species which are rarely met with outside botanical collections; but the following sections do not come within this category:—

Austrian Briar Roses: *Austrian Copper*.—Coppery-red flowers.

Austrian Yellow.—Bright yellow flowers.

Harrisonii.—Goldenyellowflowers.

Persian Yellow.—Deep yellow flowers.

Ayrshire Roses: *Bennett's Seedling* (Syn. *Thoresbyana*).—Pure white flowers in clusters. Climber.

Dundee Rambler.—White, semi-double flowers, with pink edges. Climber.

Rampant.—Pure white flowers in clusters. Climber.

Splendens (Syn. *Myrrh-scented*).—White flowers, tinted flesh colour, and semi-double. Climber.

Banksian Roses: *Alba*.—Small, white flowers in clusters, sweetly scented. Climber.

Lutea.—Small, yellow flowers in clusters. Climber.

Bourbon Roses: *Acidalie*.—White flowers, sometimes tinted pink.

J. B. M. Camm.—Pale, salmon-pink flowers.

Madame Isaac Pereire.—Bright carmine flowers.

Mrs Allen Chandler.—Pure white flowers. A sport from *Mrs Paul.*

Mrs Paul.—Blush white flowers, shaded with rosy peach.

Souvenir de la Malmaison.—Blush white flowers, deeper in centre.

Souvenir de la Malmaison, Climbing.—A climbing form of the preceding.

Boursault Roses: *Amadis* (Syn. *Crimson*).—Purplish-crimson flowers; good for pillars.

Gracilis.—Bright pink flowers; pillar.

Inermis.—Bright red flowers. Climber.

Cabbage Roses.—See PROVENCE ROSES.

China Roses: *Antoinette Guillerat.*—Rosy copper flowers, edged rose.

Arethusa.—Clear yellow flowers, shaded apricot.

Charlotte Klemm.—Fiery red, semi-double flowers.

Chin Chin.—Sulphur-yellow flowers.

Common China (or *Old Monthly Rose*).—Blush pink flowers.

Comtesse du Cayla.—Crimson-red and coppery-yellow flowers, with carmine shading.

Cramoisie Superieure.—Velvety crimson flowers.

Ducher.—Pure white flowers.

Duke of York.—Pink and white flowers.

Fabvier.—Scarlet-crimson flowers, with white centre.

Irene Watts.—Rose flowers, shading to very pale pink.

Laurette Messimy.—Rose flowers, shaded yellow.

Madame Eugène Resal.—Coppery-red to pink flowers.

Mrs Bosanquet.—Pale, flesh-coloured flowers.

Old Crimson.—Deep crimson flowers.

Queen Mab.—Rosy apricot flowers, shaded orange.

Viridiflora.—Green-petalled flowers.

Climbing Roses. See article on *ROSES FOR ALL PURPOSES.*

Damask Roses: *Commandant Beaurepaire.*—Bright red flowers, striped purplish-violet and white.

Crimson Damask.—Bright crimson, single flowers.

Lady Curzon.—Pink, single flowers.

Lady Sarah Wilson.—Creamy blush, semi-double flowers.

Madame Zoutman.—Cream flowers, tinted flesh colour.

Mrs O. G. Orpen.—Blush pink, single flowers.

York and Lancaster.—White and red flowers.

Evergreen Roses.—See article on *ROSES FOR ALL PURPOSES.*

French Roses (*Rosa gallica*): *Dometil Becard.*—White flowers, striped rose.

Oillet Flamand.—Rose flowers, striped white and red.

Perle des Panaches (Syn. *Village Maid*).—Red and lilac flowers, striped white.

Rosa Mundi.—Red flowers, striped white.

Hybrid Bourbon Roses: *Charles Lawson.*—Clear pink flowers.

Coupe d'Hebe.—Bright pink flowers.

Kathleen Harrop.—Shell pink semi-double flowers.

Purity.—White flowers, with flushed centre.

Zèphirine Drouhin.—Silvery-pink, semi-double flowers; thornless.

Hybrid China Roses: *Armosa* (Syn. *Hermosa*).—Pale pink flowers.

Blairii No. 2.—Blush flowers, with rose centre.

Field-Marshal.—Deep crimson flowers.

Fulgens.—Rich crimson flowers.

Hermosa.—See *Armosa.*

Madame Plantier.—Pure white flowers.

Vivid.—Bright scarlet flowers.

Hybrid Perpetual Roses.—This is a very large class, the best of which are mentioned in the article on *Roses for All Purposes*.

Hybrid Sweet Briar Roses.—Also called Penzance Briars.

Amy Robsart.—Deep rose flowers.

Anne of Geierstein.—Dark crimson flowers.

Brenda.—Delicate peach flowers.

Catherine Seyton. — Rosy-pink flowers.

Edith Bellenden.—Pale rose flowers.

Flora McIvor.—White flowers, with rosy flush.

Green Mantle. — Bright pink flowers, with white base to petals.

Hebe's Lip.—White flowers, with picotee edge of carmine.

Janet's Pride.—White flowers, tipped and shaded crimson.

Jeannie Deans.—Scarlet-crimson, semi-double flowers.

Julia Mannering. — Soft pink flowers.

Lady Penzance. — Soft copper flowers, bright yellow base to petals.

Lord Penzance.—Fawn flowers, shading to yellow in centre.

Lucy Ashton.—White flowers, with pink edges.

Lucy Bertram. — Deep crimson flowers, with white centre.

Meg Merrilees.—Rich crimson flowers.

Minna.—Pure white flowers.

Refulgence. — Brilliant scarlet flowers.

Rose Bradwardine.—Rose flowers.

Hybrid Tea Roses. — This class numbers several hundred varieties, and the list is constantly being added to; some of the most useful are referred to in the article on *Roses for All Purposes*.

Hybrid Wichuraiana Roses.—This class has rapidly forced its way into popular favour since the introduction of the lovely *Dorothy Perkins*, and now the list is a lengthy one. The following are some of the most noteworthy:—

Albéric Barbier. — Deep cream flowers, becoming white as they develop.

Aviateur Bleriot.—Golden-yellow flowers.

Coquina.—Pale pink, single flowers, with yellow base.

Dorothy Perkins. — Pale pink flowers.

Emily Gray. — Golden-yellow flowers, deeper in bud.

Excelsa.—Crimson flowers.

François Juranville.—Bright, rosy-fawn flowers.

Gardenia.—Yellow flowers, becoming almost white as they open.

Hiawatha.—Crimson, single flowers, with white centre.

Jersey Beauty.—Pale yellow, single flowers, opening almost white.

Lady Gay.—Rose-pink flowers.

Lady Godiva. — Salmon-pink flowers.

Léontine Gervais.—Pinkish-fawn flowers, coming near yellow as flower expands.

Minnehaha.—Deep rose flowers.

Paul Transon.—Rose-pink flowers.

Shower of Gold.—Yellow flowers, paling with age.

White Dorothy.—White sport from *Dorothy Perkins*.

Moss Roses: *Baron de Wassenaer.*—Light crimson flowers.

Blanche Moreau. — Pure white flowers.

Céline.—Bright crimson flowers.

Common or *Old Moss.*—Pink flowers.

Crested Moss.—Rose-pink flowers.

Eugène Verdier. — Vermilion-red flowers.

Henry Martin.—Deep red flowers.

Little Gem.—Crimson flowers.

Marie de Blois.—Bright rose flowers.

Salet.—Clear rose flowers.

White Bath.—White flowers.

Zenobia.—Satin-pink flowers.

Musk Roses: *Moschata alba.*—White flowers, tinted pink.

Moschata nivea.—White flowers, with black stamens.

Queen of the Musks.—Rose-pink buds; white, flushed pink when open.

Rivers' Musk.—Pink flowers, with buff shade.

Snowstorm.—Pure white, perpetual flowers.

Noisette Roses: *Aimée Vibert.*—Pure white flowers.

Alister Stella Gray.—Pale yellow flowers, with deeper centre.

Beauty of Glazenwood. — Syn. *Fortune's Yellow*, which see.

Céline Forestier. — Pale yellow flowers.

Climbing Aimée Vibert. — Pure white flowers.

Cloth of Gold.—Yellow flowers.

Fellenberg.—Rosy-crimson flowers.

Fortune's Yellow.—Yellow and carmine flowers.

Golden Queen. — Golden-yellow flowers.

Lamarque.—Pale lemon flowers.

L'Idéal.—Bronzy-red and yellow flowers.

Madame Alfred Carrière.—White flowers, with yellow base.

Maréchal Niel. — Rich yellow flowers.

Rêve d'Or.—Orange-yellow flowers.

William Allen Richardson.—Deep orange-yellow flowers, paler at edge.

Penzance Briar Roses. — See HYBRID SWEET BRIAR ROSES.

Pernetiana Roses (also called AUSTRIAN HYBRID ROSES and HYBRID BRIARS): *A. R. Goodwin.*—Coppery, orange-yellow flowers.

Beauté de Lyon.—Coral-red flowers, suffused yellow.

Cissie Easlea. — Saffron-yellow flowers, with carmine centre.

Constance.—Orange-yellow flowers.

Juliet.—Rosy-red flowers, outside of petals old gold.

Louise C. Breslau.—Pink flowers, varying to pale orange and coppery-red.

Madame E. Herriot. — Nasturtium-red flowers, changing to pink.

Rayon d'Or.—Deep yellow flowers.

Severine.—Coral-red flowers, paler when fully open.

Soleil d'Or.—Orange-yellow flowers.

Viscountess Enfield.—Coppery, old rose flowers, shaded with yellow.

Willowmere. — Shrimp-pink flowers, shaded with yellow.

Polyantha Roses[1]: *Ænnchen Muller.*—Bright rose-pink flowers.

Aschenbrödel.—Pale peach flowers, with deeper centre.

Baby Dorothy.—Dwarf form of *Dorothy Perkins.*

Baby Tausendschön.—Soft pink flowers.

Canarienvogel. — Golden-yellow and orange flowers.

Cecile Brunner.—Blush flowers, shaded pale pink.

Ellen Poulsen.—Dark pink flowers.

Erna Teschendorf.—Bright crimson flowers.

Eugènie Lamesch.—Orange-yellow flowers, shaded with carmine.

Gloire des Polyanthas.—Deep rose flowers, with white base.

Jessie.—Rosy-crimson flowers.

Katherine Zeimet.—Pure white flowers.

Léonie Lamesch. — Coppery-red flowers, with golden centre.

Madame N. Levavasseur.—Rosy-pink flowers.

Mrs W. H. Cutbush.—Deep pink flowers.

Orleans Rose. — Rosy-crimson flowers, with paler centre.

Perle d'Or. — Nankeen-yellow flowers.

Rosalind.—Bright pink flowers.

White Pet.—White flowers.

[1] The POMPON ROSES of some authorities.—EDITOR.

Yvonne Rabier.—White flowers, pale yellow at base.

Provence Roses: *Cabbage* or *Common.*—Rosy-pink flowers.

Cristata or *Crested.*—Rose flowers, with pale edge.

De Meaux or *Pompon.*—Rosy-pink flowers.

Maiden's Blush (Syn. *Celestial*).—Flesh-tinted pink flowers.

White or *Unique.*—Pure white flowers.

Rambler Roses (or *Rosa multiflora scandens,* and also called CLIMBING POLYANTHA ROSES):

Aglaia.—Bright yellow flowers.

American Pillar.—Pink flowers, with white centre.

Blush Rambler.—Pale rose flowers, with lighter centre.

Buttercup.—Deep yellow flowers, paling when open.

Claire Jacquier.—Nankeen-yellow flowers.

Crimson Rambler.—Bright crimson flowers.

Electra.—Lemon-yellow flowers.

Euphrosyne.—Light pink flowers.

Goldfinch.—Orange-yellow flowers.

Gruss an Zabern.—White flowers.

Hélène.—Pale pink flowers, tinted mauve.

Leuchstern.—Rose flowers, with white edge.

Mrs F. W. Flight.—Pink flowers, with white centre.

Philadelphia Rambler.—Rich crimson flowers.

Psyche.—Pale rosy-pink flowers.

Queen Alexandra. — Rich rose flowers.

Rubin.—Deep crimson flowers.

Tausendschön (Syn. *Thousand Beauties*).—Bright pink and carmine flowers.

Thalia.—Pure white flowers.

Trier.—Creamy white flowers.

Veilchenblau (the so-called BLUE ROSE).—Pinkish-mauve flowers.

Waltham Bride. — Pure white flowers.

Waltham Rambler. — Rosy-pink flowers.

White Tausendschön.—White sport from *Tausendschön.*

Rugosa Roses: *Alba.*—Pure white, single flowers.

Atropurpurea. — Deep crimson flowers.

Blanc double de Coubert.—Pure white flowers.

Conrad F. Meyer.—Silvery-rose flowers.

Delicata.—Soft rose flowers.

Fimbriata.—White flowers, tinted blush.

Madame Georges Bruant.—Pure white flowers.

Mrs Anthony Waterer.—Deep red flowers.

Nova Zembla.—White sport from *Conrad F. Meyer.*

Repens alba.—White flowers.

Rose à Perfum de l'Hay.—Brilliant red flowers.

Rubra.—Deep rose flowers, shaded violet.

Sweet Briar Roses: *Common.*—Pale pink flowers.

Double Scarlet.—Bright red flowers.

Double White.—White flowers, tinted flesh.

Tea Roses.—See article on *ROSES FOR ALL PURPOSES.*

Wichuraiana Roses.—See HYBRID WICHURAIANA ROSES.—W. J. C.

NEW VARIETIES.

In the following list, which includes all the best of the newer varieties, the following abbreviations are used: *H.M.* for Hybrid Musk; *H.P.* for Hybrid Perpetual; *H.T.* for Hybrid Tea; *P.* for Pernetiana; and *W.* for Hybrid Wichuraiana:—

Augustus Hartman (*H.T.*).—Geranium-red flowers, flushed with orange, and of perfect form. Suitable alike for exhibition and for bedding.

Chameleon (*H.T.*). — Coral-red flowers, shading to chrome in the

centre, and with petals shading to rose-pink.

Cheerful (*H.T.*).—Flaming orange flowers, with orange-yellow base. The blooms are large and full, making the variety splendid for both exhibition and for bedding.

Christine (*H.T.*).—Golden-yellow flowers faintly streaked red on the outside. It is a decorative and bedding variety.

Clarice Goodacre (*H.T.*).—Biscuit, chrome-coloured flowers on ivory-white base. It has pointed buds, is tangerine scented, and is alike good for decorative purposes and for exhibition.

Clytemnestra (*H.T.*). — Coppery buds opening to light salmon flowers. It is a perpetual bloomer, bearing its flowers in clusters, and makes a spreading bush 3–4 ft. high. It is alike useful for bedding and decorative purposes.

Col. Oswald Fitzgerald (*H.T.*).—Rich crimson flowers, but lighter when in bud.

Constance (*P.*).—Deep yellow buds streaked with crimson, opening to large, golden-yellow flowers. It is useful for exhibition, massing, and forcing.

Covent Garden (*H.T.*). — Bright scarlet flowers of medium size and fine shape. It is a very free flowering sort with long stems, and is useful for decorative, bedding, and forcing purposes.

Cupid (*H.T.*).—Glowing flesh-coloured flowers, opening to soft flesh pink, and with yellow stamens. It bears large single flowers in clusters, and rose-coloured hips in the autumn. It is a useful pillar and climbing rose.

C. V. Haworth (*H.T.*).—Maroon-crimson flowers with a perfect fragrance. It is useful for decorative and bedding purposes.

Edith Cavell (*H.T.*). — Lemon-white flowers with a conical centre, and with the outer petals reflexed. It is good for bedding and exhibition.

Elizabeth Cul en (*H.T.*).—Scarlet-crimson flowers of medium size, and very fragrant. It blooms very freely, and is useful alike for decorative and bedding purposes.

Flame of Fire (*H.T.*).—Bright orange or flame-coloured flowers, very freely produced, and very fragrant. It is useful for bedding, decorative purposes, and for pot culture.

Florence Spaull (*H.T.*).—Deep rose-pink flowers, very full and large, also fragrant. It is splendid for exhibition.

Frances Gaunt (*H.T.*).—Creamy-buff, large, globular flowers. It is a useful decorative and bedding rose.

Gladys Holland (*H.T.*).—Creamy-white flowers, with the back of the petals salmon. It is good for exhibition.

Golden Emblem (*H.T.*).—Large, pale yellow flowers, with crimson stripes on the outer petals. It is a good decorative and bedding rose.

Golden Ophelia (*H.T.*).—Golden-yellow centred flowers of medium size, and paler on the outside. It is a rose of fine shape, and has stout stems. It may be used for bedding, forcing, and general decorative purposes.

Hoosier Beauty (*H.T.*).—Dark crimson-scarlet, very fragrant flowers of medium size and fine shape. It is a useful decorative, forcing, and bedding rose.

Independence Day (*H.T.*).—Orange-apricot flowers in varying tints, and with the outer petals shaded pink. The blooms are of medium size, and the variety is useful for decorative and bedding purposes.

Irene Thompson (*H.T.*).—Fiery orange flowers passing to pale orange. The blooms are very large and full,

making the sort very useful alike for bedding and exhibition.

Isobel (*H.T.*).—Carmine flowers, flushed with orange-scarlet, shaded with bronze, and with a yellow centre. It bears large, single blooms which are fragrant, and it may be used as a decorative rose, or for bedding and forcing.

Janet (*H.T.*).—Buff-yellow flowers shaded with salmon. It is of dwarf habit, and may be used for decorative and bedding purposes.

K. of K. (*H.T.*).—Crimson-scarlet, semi-double flowers. It is useful for decorative purposes and for bedding.

Lady Bowater (*H.T.*).—Creamy-white flowers, suffused with blush and apricot. They are large and fully double, as well as being borne on good stems. It is a splendid rose for bedding and exhibition.

Lamia (*H.T.*).—Reddish-orange flowers of medium size. It is a useful decorative and bedding rose.

Lemon Pillar (*H.M.*).—Pale lemon buds opening to pale sulphur-yellow, and passing to lemon-white. It is suitable for pillars and walls, also for the exhibition table.

Lilian Moore (*H.T.*).—Cream outer petals, and centre pale orange. The flowers are of large size, and are fine for exhibition.

Madame Colette Martinet (*H.T.*).—Old gold flowers, shaded orange, of medium size, with long, golden-yellow buds. It is a useful decorative and bedding rose, and may be forced.

Majestic (*H.T.*).—Carmine-rose flowers of large size. It is a useful decorative and bedding rose.

Margaret Dickson Hamill (*H.T.*).—Straw-coloured flowers, edged and flushed with pale carmine. It is a decorative rose, and useful for exhibition.

Martha Drew (*H.T.*).—Salmon-pink flowers fading to blush, with the outer petals creamy-white. The flowers are large and full, with a high centre, and a tea-scent. It is a useful rose for bedding or exhibition.

Mermaid (Hybrid of *R. bracteata*).—Pale sulphur-yellow flowers with golden anthers. The buds are in large clusters, and the flowers (often 4–6 ins. across) are single. It is a perpetual flowering semi-climber, useful for low walls.

Miriam (*H.T.*).—Pale apricot-pink flowers, becoming deeper with age. It is a perpetual bloomer, with large flowers, and may be used as a decorative or bedding rose.

Miss May Marriott (*P.*).—Rich apricot flowers. It is useful for exhibition and bedding.

Miss Stewart Clarke (*H.T.*).—Golden-yellow, fragrant flowers of medium size, on stout stems. It is a useful decorative and bedding rose.

Modesty (*H.T.*).—Pearly-cream flowers, faintly tinged with rose. Its blooms are very large, and it may be used for both exhibition and bedding.

Molly Bligh (*H.T.*).—Silvery-pink flowers with a deeper centre and a yellow base. It is useful as a decorative or a bedding rose, and may be forced.

Mrs Bryce Allan (*H.T.*).—Deep carmine-rose flowers which are large and fragrant. It is useful for bedding or exhibition.

Mrs C. V. Haworth (*H.T.*).—Outer petals rosy-pink, with the inner ones apricot and salmon, and with very long petals. It is a useful decorative and bedding variety.

Mrs Elisha Hicks (*H.T.*).—Pale blush-rose, large, and very fragrant flowers. It is useful as a decorative exhibition rose, and may be forced.

Mrs George Marriott (*H.T.*).—Deep cream flowers, suffused with rosy-vermilion. It is a large, fragrant variety, of good shape,

and splendid alike for bedding and exhibition.

Mrs George Norwood (*H.T.*).—Bright pink flowers of good form, and both large and fragrant. It is good for exhibition, bedding, or forcing.

Mrs Hugh Dickson (*H.T.*).—Deep cream flowers tinted with apricot and orange. It is a splendid sort for bedding or exhibition.

Mrs Wemyss Quin (*H.T.*).—Pure yellow flowers, very freely produced on plants of good form. It is a useful decorative and bedding rose.

National Emblem (*H.T.*).—Dark velvety-crimson flowers of moderate size, fragrant, and very freely produced. It is a useful decorative and bedding rose.

Paul's Scarlet Climber (*W.*).—Bright scarlet-crimson, semi-double flowers of medium size, and in large clusters. It is useful for pillars, as a general climbing rose, and for forcing.

Pax (*H.M.*).—Pure white flowers when fully open, but lemon-tinted when in bud. Its flowers, which are semi-double, and emit a musk fragrance, are produced in large clusters on long stems throughout the summer. It is a decorative semi-climber or tall bush rose.

Princess Mary (*H.T.*).—Scarlet-crimson flowers. It is a very free sort, with large, fragrant blooms, and may be used as a decorative or bedding variety.

Sunstar (*H.T.*).—Apricot flowers of medium size, shaded with salmon-red or crimson. It is a useful decorative or bedding variety.

The Queen Alexandra Rose (*P.*).—Intense vermilion flowers, with the reverse side old gold. It is a handsome, full-petalled, fragrant rose of medium size, splendid as a decorative or bedding variety.

Ulster Gem (*H.T.*).—Deep primrose-yellow flowers of large size. It is a good decorative and bedding rose.

Victory (*H.T.*).—Glowing scarlet flowers, very large and full, borne on long stems. It is a good decorative and bedding variety.

W. C. Gaunt (*H.T.*).—Scarlet-crimson flowers, very freely produced. It is a splendid decorative and bedding variety.

W. J. C.

ROSE DE MEAUX (*Rosa parviflora*). See *ROSE SPECIES*.

ROSE DES ALPES (*Rhododendron ferrugineum* and *R. hirsutum*). See *RHODODENDRON*.

ROSE DISEASES.

[The following notes on Rose Diseases will be of interest and value to those who cultivate the Queen of Flowers.—EDITOR.]

Black Spot (*Actinonema rosae*).—This causes large black spots on the leaves, disfigures the rose bush, and may bring about severe defoliation. The fungus winters either in infected twigs, or infected evergreen leaves of certain roses, in either case producing myriads of spores in the spring ready to infect the young foliage.

REMEDIES.—In winter remove all affected leaves and twigs. In summer spray repeatedly with lime sulphur, 1 part to 50 parts of water, or dust with "flowers" of sulphur, or preferably, 90 parts finely ground sulphur and 10 parts arsenate of lead.

Rose Canker.—The term "canker" in roses covers various types of injury. In some cases it is of the nature of a "gall," and primarily due to the production of adventitious roots, and in others apparently caused by a fungus attack. The well-known canker in Maréchal Niel is of a different nature, and apparently not due to a micro-organism but to constitutional weakness. All these kinds of rose canker are in need of expert

investigation. No satisfactory remedies are known.

Rose Green Centre.—An abnormal condition due to a transformation of the central carpels of the flower into small leaf-like structures. The cause is unknown.

Rose Mildew (*Sphaerotheca pannosa*).—This is only too familiar. The leaves are twisted and deformed, and the young shoots stunted and checked by the fungus. Roses vary greatly in their susceptibility to attack. The *multiflora* section are usually badly injured, while the *Wichuraiana* series are almost immune. Hybrid teas vary.

REMEDIES. — Spray repeatedly with lime sulphur or some other good fungicide, or dust with a fine sulphur powder. In winter prune away and burn infected twigs. Resistant varieties should be chosen where mildew is troublesome.

Rose Rust (*Phragmidium subcorticatum*.—This disease weakens the young wood and may cause severe defoliation. It is common on H.P. roses and wild roses. Teas are almost immune. H.T. roses vary. The orange patches on the twigs in spring are bright and conspicuous; in the summer a second form of spore causes yellow spots on the leaves, followed by the black spots of the resting spores on the under side of the leaf. The fungus hibernates by means of resting spores and perennial mycelium in the twigs.

REMEDY. — Cut away affected twigs in autumn to remove resting mycelium, and gather up diseased leaves; spraying may be employed in spring and summer as a preventive.—A. D. C.

ROSE PLANTING.

This important operation can be divided into three headings: (1) Preparation of the soil; (2) Planting the trees; and (3) Treatment after planting.

(1) As regards the preparation of the soil, this should be done as early as possible, for planting is itself usually carried out in October and November. Gardeners who do not give time to the preparation of the soil cannot expect great things of the rose trees. There are two ways, of course, of preparing the soil: (*a*) to dig out a large hole for each tree and fill up with rubbish and fresh soil half-way, and the other half with good soil and manure; and (*b*) to dig deeply the whole of the border. The first needs no special comment or description, but there is no doubt that the second is the better. It is no waste of time to trench the beds intended for roses, and the trenching should be got through in early October, or as soon as possible, as some time must elapse for the soil to settle before planting can be safely done. Grit and sand can be mixed in if the soil is very heavy, also garden rubbish may be put into the bottom spit. But if the soil cannot be trenched, let it be well double-dug and plenty of good rotted manure mixed in with the bottom spit and the adjacent half of the top spit. Do not put the manure in layers, as so many gardeners do; try mixing it with the soil. Do not put the manure in the last 9 ins. of soil. When desired, 4 oz. of basic slag and an ounce or so of kainit both ground fine may be scattered over about a square yard of the bed and lightly

pricked in. This should be added as soon as possible to the soil, for it takes some time to dissolve, as all know.

(2) Of course all readers know not to attempt to plant the trees in frosty weather. The trees can be laid-in in some warm spot, and unless they are very tender should come to no harm if the roots are well covered with soil and an old mat thrown over them. In an open spell,—even a day or two,—which we may get in November, go out and get the work through. If you are planting standards, climbers, or pole-ramblers, have ready stakes, poles, or supports of sufficient strength. Fetch out a hole bigger than the area of the rose's roots when arranged fanwise from the collar, and see that it is of depth approximate to that which the rose was originally planted. But you need not in all cases adhere to this, for some nurserymen plant deeper than necessary, for certain vague purposes of their own. Let the bottom of the hole slope downwards a little all round to the edges, rather than the other way. Spread out the roots evenly and carefully as far as you can, and get some one to hold the tree while you drive in the stake or fix in the pole if it needs one. Gardeners should be careful about damaging the roots of roses, and, if any are accidentally broken, the damaged pieces should be cut off clean with a sharp knife. Roses should be planted firmly, and tied at once to their stakes or poles, if any. Cover the roots and fill up the hole with the soil dug out, being careful that no manure comes into direct contact with the root fibres. Firm the trees well as the filling of the hole is in progress, after which make the ground level and tidy.

(3) Do not mulch newly planted roses, but wait till the spring to do this. The after-treatment of newly planted roses is not great, but still should not be neglected. Gardeners should bear in mind that roses are loosened by frost, or harm may be done. After a thaw go round and firm the trees at once. Do this, of course, with your foot. This treatment will have to be repeated periodically all the winter.

As regards protection many do not need it in average winters. But if roses which are a little tender be grown as climbers on walls or over arches, they can be protected by pieces of matting tacked or tied over the growths, and some gardeners cover the roots with straw, or again by putting pieces of old matting over them. It would, of course, be inconvenient to keep on removing and replacing such protections, so if it be really necessary to use them they should be put on soon after planting and not removed till March. It must be remembered that climbers and others should have their growths secured, or in windy weather these may be damaged. The wind, while tossing these about, often pulls at the roots of the rose trees, so it is necessary to plant all kinds firmly, and tie up any that need it securely.

E. T. E.

ROSE ROOT (*Sedum roseum*).—See *SEDUM*.

ROSE RUST.—See *ROSE DISEASES*.

ROSE SAWFLIES and ROSE SLUG-WORM.—See *INSECT PESTS*.

ROSE SPECIES.

A few notes on some of the best species are given below:—

Rosa alba.—This and its variety *suaveolens* bear white flowers from June onwards, and grow about 4 ft. in height.

R. alpina.—This bears blush-pink flowers from June to August, and

averages 3–6 ft. in height. The hybrid between it and *R. indica* is known as the BOURSAULT ROSE.

R. arvensis (AYRSHIRE ROSE).—This bears white flowers from June to August, while pink or flesh-coloured varieties of it are also available. The height averages 3–20 ft.

R. Banksiae (BANKSIAN ROSE).—This bears pure white and light buff-yellow flowers from June onwards, and may attain a height of 20 ft.

R. beggeriana.—This bears white flowers from June to August, and grows about 5 ft. high. Its varieties *nigrescens* and *Schrenki* might also be grown.

R. blanda.—This bears pretty red flowers from May to July on plants 3–6 ft. in height. Its varieties *arkansana, Sayi, setigera,* and *willmottiana* should also be grown.

R. bourbonia (BOURBON ROSE).—This bears purple flowers from June to August, and grows 8–10 ft. high.

R. bracteata (MACARTNEY ROSE).—This bears white flowers from July onwards, and averages about 2 ft. high.

R. canina (DOG ROSE).—About fifteen varieties of this figure in the *Kew Hand-list of Trees and Shrubs.* It is one of the stocks on which many roses are grafted, but in itself is quite unworthy of cultivation, save in the wild garden. It bears, according to the variety, glowing crimson-pink or purple flowers in June, and averages 6–8 ft. in height.

R. cinnamomea. — This bears charming pink flowers from May to June, and grows 5–6 ft. in height. Its varieties *flore pleno* (double), *glandulifolia,* and *sibirica* might also be grown.

R. damascena (DAMASK ROSE).—This bears lovely pink flowers from June onwards, and grows about 1 yd. in height. Its variety *variegata,* the flowers of which are striped, is known as the YORK AND LANCASTER ROSE.

R. ferruginea.—This bears small, rose flowers, but is prized for its plum coloured foliage and "rust-coloured" branches and twigs. It has numerous scarlet hips, and grows from 5–10 ft. high.

R. gallica.—This, known by some as the FRENCH ROSE, bears pink flowers in June, and grows ¾–2½ ft. in height. It has very numerous varieties. Of these, *muscosa* is the MOSS ROSE, while *provincialis* is the PROVENCE ROSE.

R. indica (MONTHLY ROSE).—This is available in many varieties, most of which bloom from June to the end of the summer. The type is, however, seldom without flowers. There is a good colour range, containing blush-pink, red, rose, white, and yellow. The variety *minima* is known as the FAIRY ROSE, and *sanguinea* is the CRIMSON CHINA ROSE. The height averages 1–20 ft.

R. laevigata (CHEROKEE ROSE).—This bears white flowers from June onwards, and averages 4–6 ft. in height.

R. lutea (AUSTRIAN BRIAR).—This bears yellow flowers from June onwards, and averages 3–4 ft. in height.

R. moschata (MUSK ROSE).—This bears white flowers from August onwards, and averages 12–20 ft. in height. Its varieties *flore pleno* and *Pissarti* are also worthy of inclusion.

R. Moyesii.—This bears bright red flowers from June to August, and grows 6–10 ft. high.

R. multiflora. — This bears red flowers from June onwards, and averages 10–15 ft. high. Its varieties *flore pleno* and *Thunbergii,* also its hybrids with *R. indica* and *R. moschata,* are worthy of inclusion.

R. nitida.—This bears bright red flowers in July and August on plants about 1 yd. high. The foliage is prettily tinted in the autumn.

R. noisettiana (NOISETTE ROSE).—This bears red flowers from July onwards on plants attaining a height of 3 ft.

R. nutkana (WASATCH ROSE).—This bears flowers of all shades of red from June onwards, and grows 3–6 ft. high.

R. parviflora (ROSE DE MEAUX).—This bears flowers of the palest rose from July onwards, and averages 1½–2 ft. in height.

R. pomifera (APPLE ROSE).—This bears red flowers from June to October, and averages 4½ ft. in height.

R. rubiginosa (EGLANTINE or SWEET BRIAR).—This is an old favourite bearing pink flowers from June to July on plants about 5 ft. high.

R. rugosa (JAPANESE ROSE).—This and its numerous varieties bear red and white flowers from June to September, and grow –6 ft. high.

R. sempervirens.—This bears pure white flowers from June onwards, and grows up to about 20 ft. high.

R. sericea.—This bears white flowers from May to July, on plants 5–10 ft. in height.

R. setigera (PRAIRIE ROSE).—This bears rose-coloured flowers from June onwards, on plants 10–25 ft. high.

R. spinosissima (BURNET ROSE or SCOTCH ROSE).—This and its numerous varieties bear yellow, white, and red flowers from May onwards, the height of the plants averaging 2–4 ft.

R. wichuraiana (WICHURAIANA ROSE).—This bears pure white flowers from June onwards, and has a prostrate habit of growth. Its variety *rubra* is bright red. It is much used as a climber, and has given rise to numerous garden varieties.

R. xanthina.—This bears yellow flowers throughout the summer, and grows 3–6 ft. high.

For garden varieties of the majority of these species reference should be made to our article on *ROSE CLASSES*, in which the various groups are given under their best known names.

ROSE VERVAIN (*Verbena Aubletia*).—See *VERBENA SPECIES*.

ROSEMARY.—The genus ROSMARINUS and *R. officinalis*. See *POTHERBS* and *SHRUBS*.

ROSES: DISEASES OF.—See *ROSE DISEASES*.

ROSES FOR ALL PURPOSES.

It is safe to say that no plant is capable of more varied application for the purposes of the gardener than is the Rose. It is merely necessary to glance at the following paragraphs to realise this, and to understand how rightly the Rose is called THE QUEEN OF FLOWERS. The following abbreviations are used to denote the different classes: *C.* China; *H.B.* Hybrid Bourbon; *H.P.* Hybrid Perpetual; *H.T.* Hybrid Tea; *N.* Noisette; *P.* Pernetianas or Austrian Hybrids; *T.* Tea; and *W.* Wichuraianas.

Roses for Arbours, Arches, and Pergolas.—For this purpose the Wichuraiana Roses are greatly favoured, as they give, when in bloom, a glorious mass of colour (for colours see HYBRID WICHURAIANAS in the article *ROSE CLASSES*); but they have the drawback of flowering once only during the season. They do not bloom all at the same time, however, and by planting early, mid-season, and late varieties, a much longer period of blooming can be assured—from June to late August, or even into September. The following list gives a guide to the approximate period of flowering, the mid-season sorts coming on as the earlier ones are getting past their best, and the late varieties overlapping those:—

EARLY-FLOWERING.—*Albéric Barbier, Auguste Barbier, Aviateur Bleriot, Climbing American Beauty, Eliza Robichon, François Guillot,*

Gardenia, Gerbe Rose, Jersey Beauty, Joseph Billard, Paul Transon, René André, Robert Craig, Ruby Queen, Shower of Gold.

MID-SEASON.—*Anna Rubsamen, Débutante, Edmond Proust, François Juranville, Jean Guichard, Joseph Liger, Léontine Gervais, Manda's Triumph, Milky Way, Rubra, Schneeball, Valentine Beaulieu.*

LATE-FLOWERING.—*Christian Curle, Dorothy Perkins, Excelsa, Hiawatha, Lady Gay, Lady Godiva, Minnehaha, Mrs Littleton Dewhurst, Paul Ploton, Sweetheart, The Farquhar, White Dorothy, Wichuraiana.*

The RAMBLER ROSES (multiflora or Climbing Polyantha section), as well as the AYRSHIRE ROSES (for both of which see the article on *ROSE CLASSES*), are likewise good for this purpose, but with them, too, there is only a comparatively brief season. There is, however, a good selection of Roses for Arches, etc., that flower more or less freely throughout the season, principally in the Hybrid Tea, Noisette, and Tea Sections. Among the best of these are the following:—

Alister Stella Gray (*N.*).—Pale yellow flowers with orange centre.

Ards Rover (*H.P.*).—Dark crimson flowers.

Bouquet d'Or (*DIJON T.*).—Yellow and buff flowers.

Carmine Pillar (*H.T.*).—Rosy-carmine, single flowers.

Climbing Aimée Vibert (*N.*).—White flowers.

Climbing Caroline Testout (*H.T.*).—Silvery-pink flowers.

Climbing Mrs W. J. Grant (*H.T.*).—Bright rosy-pink flowers.

Climbing Richmond (*H.T.*).—Rich scarlet flowers.

Gloire de Dijon (*T.*).—Buff flowers with orange centre.

Longworth Rambler (*H.T.*).—Light crimson, semi-double flowers.

Madame Alfred Carrière (*N.*).—White flowers.

Reine Marie Antoinette (*H.T.*).—Cherry-red flowers.

Reine Olga de Wurtemberg (*H.T.*).—Rosy-crimson flowers.

Rêve d'Or (*N.*).—Buff-yellow flowers.

William Allen Richardson (*N.*).—Orange-yellow flowers.

Roses for Bedding.—The multiplicity of Roses now in commerce gives almost illimitable scope for the exercise of individual choice, so that the following lists are put forward rather as suggestions, and because the varieties named have been proved suitable for the purpose. They are, in the majority of cases, good for autumn flowering. It should be remembered that Roses vary in average height, and that in bedding it is advisable to put the taller-growing varieties in positions where they will not hide the others. The tall varieties are here put in a separate list. For the front of the bed the dwarf Polyanthas are well adapted, and a list of these will be found in the article on *ROSE CLASSES*.

DWARF TO MEDIUM HEIGHT.—*Alexander Hill Gray.* (*T.*).—Deep lemon and yellow flowers.

Arthur R. Goodwin (*P.*).—Coppery-orange flowers.

Augustine Guinoisseau (*H.T.*).—White, tinted blush flowers.

Betty (*H.T.*).—Coppery-rose flowers, shaded with yellow.

Brilliant (*H.T.*).—Intense scarlet flowers.

British Queen (*H.T.*).—Creamy-white flowers.

Captain Hayward (*H.P.*).—Scarlet-crimson flowers.

Caroline Testout (*H.T.*).—Silvery-pink flowers.

Charles de Lapisse (*H.T.*).—Blush flowers.

Chateau de Clos Veugeot (*H.T.*).—Dark crimson flowers.

Clara Watson (*H.T.*). — Pale flesh flowers, tinted with rosy-peach.

Claudius (*H.T.*).—Bright crimson flowers.

Comtesse du Cayla (*C.*).—Nasturtium-red flowers.

Countess of Derby (*H.T.*).—Rose flowers with salmon centre.

Countess of Shaftesbury (*H.T.*).—Rose-pink flowers.

Dora van Tets (*H.T.*).—Deep crimson flowers.

Dorothy Page Roberts (*H.T.*).—Coppery-pink flowers, suffused with yellow.

Dr J. Campbell Hall (*H.T.*).—Coral-rose flowers.

Duchess of Wellington (*H.T.*).—Saffron-yellow flowers.

Earl of Warwick (*H.T.*).—Salmon-pink flowers.

Ecarlate (*H.T.*).—Scarlet flowers.

Edu Meyer (*H.T.*).—Coppery-yellow flowers, shaded with yellow.

Edward Mawley (*H.T.*).—Deep crimson flowers.

Ethel Malcolm (*H.T.*).—Ivory-white flowers, shaded with peach.

General McArthur (*H.T.*).—Bright crimson flowers.

George C. Waud (*H.T.*).—Orange-vermilion flowers.

Gustav Grünerwald (*H.T.*).—Carmine flowers.

Harry Kirk (*H.T.*). — Sulphur-yellow flowers.

Hon. Ina Bingham (*H.T.*).—Rich pink single flowers.

Hugo Roller (*T.*).—Lemon-yellow flowers with rose edge.

Irish Elegance (*H.T.*).—Bronzy-orange in bud, but opens to apricot flowers. Single.

Irish Fireflame (*H.T.*).—Fiery-orange in bud, but opens to pale crimson flowers. Single.

Jonkheer J. L. Mock (*H.T.*).—Carmine-pink flowers.

Joseph Lowe (*H.T.*). — Blush flowers.

Kaiserin Augusta Victoria (*H.T.*).—Creamy-white flowers.

Killarney (*H.T.*).—Soft pink flowers.

La France (*H.T.*). — Rosy-pink flowers.

Lady Alice Stanley (*H.T.*).—Silvery-pink flowers.

Lady Ashtown (*H.T.*).—Deep pink flowers.

Lady Battersea (*H.T.*).—Cherry-crimson flowers.

Lady Hillingdon (*T.*).—Orange-yellow flowers.

Lady Pirrie (*H.T.*).—Coppery, salmon-pink flowers.

Lady Roberts (*T.*). — Reddish-apricot flowers.

Lady Ursula (*H.T.*).—Flesh-pink flowers.

Laurent Carle (*H.T.*).—Velvety-crimson flowers.

Le Progrès (*H.T.*).—Nankeen-yellow flowers.

Leslie Holland (*H.T.*).—Scarlet-crimson flowers.

Lieut. Chauré (*H.T.*).—Velvety-crimson flowers.

Lohengrin (*H.T.*). — Silvery-pink flowers.

Louise Catherine Breslau (*P.*).—Shrimp-pink flowers, shaded with yellow.

Mabel Drew (*H.T.*).—Cream, passing to yellow flowers.

Madame Abel Chatenay (*H.T.*).—Carmine flowers, shaded with salmon.

Madame Edouard Herriot (*P.*).—Terra-cotta-red flowers.

Madame Eugène Resal (*C.*).—Coppery-rose flowers, shaded with orange.

Madame Jules Grolez (*H.T.*).—Silvery-rose flowers.

Madame Lambard (*T.*).—Salmon-rose flowers.

Madame Leon Pain (*H.T.*).—Silvery-salmon flowers.

Madame Mélanie Soupert (*H.T.*).—Salmon-yellow flowers, suffused with carmine.

Madame Ravary (*H.T.*).—Orange-yellow flowers.

Madame Segond-Weber (*H.T.*).—Rosy-salmon flowers.

Marquise de Sinety (*H.T.*).—Golden-yellow flowers, shaded with bronzy-red.

Melody (*H.T.*).—Saffron-yellow flowers, with paler edges.

Milady (*H.T.*).—Rich scarlet flowers.

Mons. Joseph Hill (*H.T.*).—Salmon-pink flowers, shaded with yellow.

Mrs Aaron Ward (*H.T.*).—Indian yellow flowers, with pale edges.

Mrs Alfred Tate (*H.T.*).—Coppery-salmon flowers, shaded fawn.

Mrs A. R. Waddell (*H.T.*).—Reddish-orange flowers.

Mrs Arthur E. Coxhead (*H.T.*).—Claret-red flowers.

Mrs C. Curtis Harrison (*H.T.*).—Deep pink flowers.

Mrs C. E. Pearson (*H.T.*).—Orange-red flowers, with apricot shading.

Mrs Edward Powell (*H.T.*).—Scarlet flowers, shaded with crimson.

Mrs Herbert Stevens (*T.*).—White flowers.

Mrs James Lynas (*H.T.*).—Pearly-pink flowers.

Mrs Peter Blair (*H.T.*).—Lemon flowers, deeper in centre.

Mrs R. G. Sharman Crawford (*H.P.*).—Rosy-pink flowers.

Mrs T. Hillas (*H.T.*).—Chrome-yellow flowers.

Mrs Wakefield Christie-Miller (*H.T.*).—Blush and vermilion flowers.

Mrs W. J. Grant (*H.T.*).—Bright rosy-pink flowers.

Old Gold (*H.T.*).—Orange flowers, tinted with copper.

Ophelia (*H.T.*).—Salmon-flesh flowers, rosier in centre.

Pharisaër (*H.T.*).—Rosy-white flowers, shaded with salmon.

Prince Camille de Rohan (*H.P.*).—Dark crimson flowers.

Prince de Bulgarie (*H.T.*).—Pale rose flowers, shaded with apricot.

Queen Mab (*C.*).—Rosy-apricot flowers, shaded with orange.

Rayon d'Or (*P.*).—Golden-yellow flowers.

Red Letter Day (*H.T.*).—Scarlet-crimson flowers.

Richmond (*H.T.*).—Rich scarlet flowers.

Viscountess Folkestone (*H.T.*).—Creamy-white flowers, shaded with flesh.

Warrior (*H.T.*).—Crimson-scarlet flowers.

White Killarney (*H.T.*).—White flowers with creamy centre.

TALL-GROWING VARIETIES FOR BEDDING.—*Avoca* (*H.T.*).—Scarlet-crimson flowers.

Ben Cant (*H.P.*).—Deep crimson flowers.

Dupuy Jamain (*H.P.*).—Bright cerise flowers.

Florence H. Veitch (*H.T.*).—Scarlet-crimson flowers.

Frau Karl Druschki (*H.P.*).—Bright crimson flowers.

General Jacqueminot (*H.T.*).—Scarlet-crimson flowers.

Gruss an Teplitz (*H.T.*).—Scarlet-crimson flowers.

Gustave Régis (*H.T.*).—Nankeen-yellow flowers.

Hugh Dickson (*H.P.*).—Rich crimson flowers.

J. B. Clark (*H.T.*).—Scarlet flowers, shaded with plum.

Juliet (*P.*).—Flowers rosy-red inside of petals, and old gold outside.

La Tosca (*H.T.*).—Creamy-rose flowers.

Lady Waterlow (*H.T.*).—Salmon-pink flowers, edged with carmine.

Madame Wagram (*H.T.*).—Rose flowers, shaded with flesh-pink.

Mrs J. H. Welch (*H.T.*).—Rose-pink flowers.

Mrs John Laing (*H.P.*).—Soft pink flowers.

Mrs Stewart Clark (*H.T.*).—Cerise-pink flowers.

Simplicity (*H.T.*).—White, single flowers.

Ulrich Brunner (*H.P.*).—Cherry-red flowers.

Zéphirine Drouhin (*H.B.*).—Carmine-pink flowers.

Roses for Buttonholes.—While it may be said that almost any rose, if not too large, can be used for buttonholes, there are some varieties, such as the following, that seem especially adapted to this purpose :—

Amateur Teyssier (*H.T.*).—White flowers with pale yellow centre.

Countess of Derby (*H.T.*).—Rose flowers with salmon centre.

Gustave Régis (*H.T.*).—Nankeen-yellow flowers.

Hugo Roller (*T.*).—Lemon-yellow flowers with rose edge.

Isabella Sprunt (*T.*).—Orange-yellow flowers.

Lady Hillingdon (*T.*). — Deep apricot-yellow flowers.

Lady Roberts (*T.*). — Reddish-apricot flowers.

Liberty (*H.T.*).—Brilliant crimson flowers.

Ma Capucine (*T.*). — Bronzy-yellow flowers, shaded with red.

Madame Chédane Guinoisseau (*T.*). —Canary-yellow flowers.

Madame Colette Martinet (*H.T.*). —Old gold flowers, shaded with orange.

MadameFalcot (*T.*).—Rich orange-yellow flowers.

Madame Jean Dupuy (*T.*).—Reddish-yellow flowers.

Madame Pernet Ducher (*H.T.*).—Canary-yellow flowers, becoming almost white.

Margaret Molyneux (*H.T.*).—Yellow flowers, shaded with pink.

Rosette de la Legion d'Honneur (*H.T.*).—Carnation-red flowers with yellow centre.

Safrano (*T.*). — Bright apricot flowers.

Souvenir de Catherine Guillot (*T.*). —Coppery-carmine flowers.

Sunrise (*T.*).—Carmine flowers with salmon-pink centre.

William Allen Richardson (*N.*).—Orange-yellow flowers.

In addition to these, many of the single roses, such as *Irish Elegance* and *Irish Fireflame*, are very fine in the bud state.

Roses for Exhibition : HYBRID PERPETUAL.—Though, for garden and decorative purposes, this class is being rapidly superseded by the Hybrid Teas, which more truly deserve the title of "perpetual," it still supplies a number of varieties of highest quality for exhibition. Indeed, for form and rich colour many of them are unsurpassable, and no collection could be deemed complete that did not include some of the following :—

Alfred Colomb. — Bright red flowers.

Alfred K. Williams.—Carmine-red flowers.

Baroness Rothschild.—Pale rose-pink flowers.

Beauty of Waltham.—Rosy-crimson flowers.

Ben Cant.—Deep crimson flowers with darker centre.

Candeur Lyonnaise. — White flowers, sometimes faintly tinted with pale lemon-yellow.

Captain Hayward.—Scarlet-crimson flowers.

Charles Lefebvre.—Brilliant crimson flowers.

Commandant Félix Faure.—Rich crimson-lake flowers, flushed with vermilion.

Comte de Raimbaud.—Dark carmine-cerise flowers.

Coronation.—Flesh flowers, shading to bright shrimp-pink.

Dr Andry. — Bright crimson flowers.

Duke of Edinburgh.—Bright vermilion flowers.

Duke of Wellington.—Velvety-red and crimson flowers.

Earl of Dufferin. — Velvety-crimson flowers, shaded with maroon.

E. Y. Teas.—Bright red flowers.

Fisher Holmes.—Dark crimson-scarlet flowers.

Frau Karl Druschki.—Pure white flowers.

George Arends.—A rose-coloured sort with " Druschki " flowers.

Gloire de Chédane Guinoisseau.—Crimson flowers.

Gustave Piganeau.—Brilliant carmine flowers.

Helen Keller.—Rosy-cerise flowers.

Her Majesty.—Clear rosy-pink flowers.

Horace Vernet. — Velvety-red flowers, shaded with dark crimson.

Hugh Dickson.—Brilliant crimson flowers.

Louis van Houtte.—Deep crimson flowers, shaded with maroon.

Madame Eugène Verdier.—Satiny-rose flowers.

Madame Gabriel Luizet.—Silvery-pink flowers.

Madame Victor Verdier.—Light crimson flowers.

Marchioness of Londonderry.—Ivory-white flowers.

Marie Baumann.—Bright carmine flowers.

Maurice Bernardin.—Vermilion flowers.

Mrs John Laing.—Soft pink flowers.

Mrs R. G. Sharman Crawford.—Deep rosy-pink flowers.

Oscar Cordel.—Bright carmine flowers.

Prince Arthur.—Deep crimson flowers.

Rev. Alan Cheales.—Pure lake flowers with silvery-white reverse.

Reynolds Hole.—Deep maroon flowers, shaded with crimson.

Suzanne Marie Rodocanachi.—Rosy-cerise flowers.

Ulrich Brunner. — Cherry-red flowers.

Ulster.—Bright salmon flowers.

Victor Hugo.—Rich crimson flowers, shaded with purple.

Xavier Olibo.—Velvety-crimson flowers.

Hybrid Teas.—In this section additions are constantly being made, and the list of varieties suitable for exhibition is far too lengthy to be included here in its entirety. Many of those given here are good also for bedding and decoration, the treatment, of course, being somewhat different. The following list comprises sixty varieties that are well up to exhibition standard, but does not include any introduced since 1915 :—

Alice Cory Wright.—Deep pink flowers.

Alice Lindsell. — Creamy-white flowers with pink centre.

Augustus Hartmann.—Geranium-red flowers.

Avoca.—Scarlet-crimson flowers.

Bessie Brown. — Creamy-white flowers.

British Queen. — Pure white flowers.

Caroline Testout. — Silvery-pink flowers.

Charles de Lapisse. — Blush flowers.

Claudius.—Bright rose flowers.

Colleen.—Bright rose flowers, shaded with pink.

Countess Clanwilliam. — Pink flowers tipped with red.

Dean Hole.—Carmine flowers, shaded with salmon.

Dr O'Donel Browne.—Carmine-rose flowers.

Duchess of Normandy.—Salmon-flesh flowers, paling to cream at the edges.

Earl of Gosford.—Dark crimson flowers.

Earl of Warwick.—Salmon-pink flowers, shaded with rose.

Edward Bohane.—Velvety-crimson flowers.

Edward Mawley.—Deep velvety-crimson flowers.

Elizabeth.—Deep rosy-pink flowers, lighter on the outer petals.

Ferniehurst.—Coppery, rose-pink flowers, on fawn base.

Florence Forrester.—Snow-white flowers with a lemon tinge.

Florence Pemberton. — Creamy-white flowers, edged blush.

George Dickson.—Velvety-black crimson flowers.

Gladys Harkness.—Deep salmon-pink flowers.

H. Vessey Machin. — Scarlet-crimson flowers.

His Majesty.—Dark crimson flowers.

J. B. Clark.—Deep scarlet flowers, shaded with plum.

Jonkheer J. L. Mock.—Deep pink flowers with a silvery reserve.

King George V.—Blackish-crimson flowers with a violet flush.

Lady Helen Vincent.—Shell-pink flowers.

Lady Moyra Beauclerc.—Madder-rose flowers with a silvery reflex.

Lady Ursula.—Flesh-pink flowers.

Leslie Holland.—Scarlet-crimson flowers with a deeper shading.

Lohengrin.—Silvery-pink flowers with a deep pink centre.

Lyons-Rose.—Shrimp-pink flowers with a coral-red centre.

Mabel Drew.—Deep cream flowers, passing to canary-yellow.

Madame Maurice de Luze.—Rose-pink flowers with a carmine centre.

Madame Wagram (Syn. *Comtesse de Turenne*).—Rose flowers, shaded with flesh-pink.

Margaret.—Soft pink flowers.

Marquise de Ganay.—Silvery-pink flowers.

Marquise Litta. — Rosy-carmine flowers.

Mildred Grant. — Ivory-white flowers, tinted with peach.

Mrs Ambrose Riccardo.— Deep honey-yellow flowers.

Mrs Andrew Carnegie. — Pure white flowers.

Mrs Archie Gray.—Light canary-yellow flowers.

Mrs Charles Russell.—Rosy-carmine flowers.

Mrs Cornwallis West.—Delicate pinkish-white flowers.

Mrs David McKee. — Creamy-yellow flowers.

Mrs George Norwood. — Bright pink flowers.

Mrs James Lynas. — Pearly-pink flowers.

Mrs J. H. Welch. — Rose-pink flowers.

Mrs Muir Mackean.—Carmine-crimson flowers.

Mrs R. D. McClure.—Salmon-pink flowers.

Mrs Richard Draper.—Rosy-pink flowers; silvery-flesh on inside of the petals.

Mrs Theodore Roosevelt.—Creamy-white flowers.

Naarden.—Creamy-white flowers with salmon centre.

Oberhofgartner Terks. — Light salmon-pink flowers.

Queen of Spain. — Pale flesh-coloured flowers with darker centre.

St Helena.—Cream flowers with blush centre.

William Shean.—Pink flowers.

TEAS.—In this section are to be found some of the most beautiful of all Roses, and in many exhibitions special classes are given over to them. The following are some of the best exhibition varieties :—

Alexander Hill Gray. — Clear lemon-yellow flowers.

Anna Olivier.—Rosy-flesh and buff flowers.

Bridesmaid.—Bright pink flowers.

Catherine Mermet.—Light rosy-flesh flowers.

Comtesse de Nadaillac.—Peach flowers, shaded apricot and coppery-yellow.

Freiherr von Marschall.—Crimson flowers, opening to rose.

Innocente Pirola.—Cream flowers, tinted with pink.

Lady Plymouth.—Ivory flowers, faintly flushed.

Madame Constant Soupert.—Golden-yellow flowers.

Madame de Watteville.—Cream flowers, tinted with rose.

Madame Jules Gravereux.—Flesh-coloured flowers, shaded with yellow.

Maman Cochet.—Pale pink flowers, shaded with salmon.

Maréchal Niel.—Golden-yellow flowers.

Medea.—Lemon flowers with deeper centre.

Molly Sharman Crawford.—Eau-de-nil white flowers.

Mrs Campbell Hall.—Creamy-buff flowers, suffused with rose.

Mrs Edward Mawley.—Carmine flowers, shaded with salmon.

Mrs Foley Hobbs.—Ivory-white flowers with a faint flush of pink on the edges of the petals.

Mrs Herbert Hawkesworth.—Creamy-white flowers.

Mrs Hubert Taylor.—Creamy-white flowers, suffused with pale rose.

Mrs Myles Kennedy.—Silvery-white flowers, shaded buff.

Muriel Grahame.—Pale cream flowers, flushed with rose.

Rubens.—White flowers, shaded creamy-rose.

Souvenir d'Elise Vardon.—Creamy-white flowers with centre tinted rose.

Souvenir d'un Ami.—Pale rose flowers.

Souvenir de Pierre Notting.—Apricot-yellow flowers, shaded with orange.

Souvenir de S. A. Prince.—Pure white flowers.

The Bride.—White flowers, tinged with lemon.

W. R. Smith.—White flowers, flushed with rosy-pink.

White Maman Cochet.—White flowers, tinged with blush.

Roses for Fragrance.—To many growers fragrance is a matter of no moment, compared with form and colour; but to others it is a keen disappointment that so many fine Roses lack this charm. In the old-fashioned Hybrid Perpetuals fragrance was more common than it is among the present race of Hybrid Teas; it is, however, satisfactory to note that many of these are deliciously scented, and some raisers make this one of their ideals. In the lists of Roses for Exhibition and for Bedding are some in which fragrance is especially pronounced, and their names are here given. It must not be assumed, however, that all those not mentioned are absolutely scentless.

FRAGRANT HYBRID PERPETUALS.—*A. K. Williams, Charles Lefebvre, Coronation, Dupuy Jamain, Fisher Holmes, General Jacqueminot, Horace Vernet, Hugh Dickson, Madame Victor Verdier, Marie Baumann, Mrs John Laing, Prince Camille de Rohan, Ulrich Brunner, Xavier Olibo.*

FRAGRANT HYBRID TEAS.—*Augustine Guinoisseau, Avoca, Betty, British Queen, Chateau du Clos Vougeot, Claudius, Dorothy Page-Roberts, Dr O'Donel Browne, Duchess of Wellington, Ecarlate, Edward Mawley, Florence H. Veitch, General McArthur, George Dickson, Gladys Harkness, Gruss an Teplitz, Gustav Grünerwald, La France, Lady Alice Stanley, Lady Helen Vincent, Lieut. Chauré, Mabel Drew, Madame Abel Chateney, Madame Maurice de Luze, Madame Ravary, Mrs A. Carnegie, Mrs Alfred Tate, Mrs Arthur E. Coxhead, Mrs J. H. Welch, Mrs Muir MacKean, Mrs Peter Blair, Mrs Stewart Clark, Old*

Gold, Princess Mary, Richmond, Viscountess Folkestone.

FRAGRANT TEAS.—Practically all the Roses in this section have the special "Tea" fragrance in varying degree.

Roses for Greenhouse and Conservatory.—For pot culture under glass the varieties suitable are countless, and to name a few of the best is all that is possible here. They are as follows: *British Queen* (*H.T.*); *Candeur Lyonnaise* (*H.P.*); *Caroline Testout* (*H.T.*); *Catherine Mermet* (*T.*); *Charles de Lapisse* (*H.T.*); *Constance* (*P.*); *Covent Garden* (*H.T.*); *Earl of Warwick* (*H.T.*); *Edward Mawley* (*H.T.*); *Exquisite* (*H.T.*); *Florence Pemberton* (*H.T.*); *Frau Karl Druschki* (*H.P.*); *General McArthur* (*H.T.*); *Golden Ophelia* (*H.T.*); *Hadley* (*H.T.*); *Hoosier Beauty* (*H.T.*); *Iona Herdman* (*H.T.*); *Killarney* (*H.T.*); *Lady Alice Stanley* (*H.T.*); *Lady Hillingdon* (*T.*); *Lady Pirrie* (*H.T.*); *Leslie Holland* (*H.T.*); *Liberty* (*H.T.*); *Lieut. Chauré* (*H.T.*); *Madame Abel Chateney* (*H.T.*); *Madame Edouard Herriot* (*P.*); *Madame Hoste* (*T.*); *Madame Leon Pain* (*H.T.*); *Melody* (*H.T.*); *Mrs A. Carnegie* (*H.T.*); *Mrs D. Jardine* (*H.T.*); *Mrs George Norwood* (*H.T.*); *Mrs George Shawyer* (*H.T.*); *Mrs Herbert Stevens* (*T.*); *Mrs Joseph H. Welch* (*H.T.*); *Niphetos* (*T.*); *Old Gold* (*H.T.*); *Ophelia* (*H.T.*); *Pharisaër* (*H.T.*); *Prince de Bulgarie* (*H.T.*); *Princess Mary* (*H.T.*, single); *Rayon d'Or* (*P.*); *Richmond* (*H.T.*); *Safrano* (*T.*); *Souvenir de Pierre Notting* (*T.*); *The Bride* (*T.*); *Ulrich Brunner* (*H.P.*); *Viscountess Folkestone* (*H.T.*); *White Killarney* (*H.T.*); *William Shean* (*H.T.*).

CLIMBERS.—*Climbing Devoniensis* (*T.*); *Climbing Liberty* (*H.T.*); *Climbing Mrs W. J. Grant* (*H.T.*); *Climbing Niphetos* (*T.*); *Climbing Souvenir de Pierre Notting* (*T.*); *E. Veyrat Hermanos* (*T.*); *Fortune's Yellow* (*N.*); *Maréchal Niel* (*N.*); *Tausendschön* (climbing polyantha); *W. A. Richardson* (*N.*).

Roses for Hedges. — Where a hedge of moderate height is required, there are many fine Roses available. Impenetrability can be secured by planting in a double row, the back alternating with the front, with a space of 2½–3 ft. between the bushes. Any of the strong-growing China Roses are suitable, also the varieties of *Rosa rugosa*, and the Hybrid Sweet Briars. Particulars of these will be found in the article on *ROSE CLASSES*, which see. The following are specially recommended:—

Fellenberg (*N.*), rosy-crimson; *Gruss an Teplitz* (*H.T.*), bright crimson, semi-double; *Moyesii* (species), dull crimson, single, with yellow stamens; *Stanwell Perpetual* (Perpetual Scotch), pale blush; *Xanthina* (species), pale yellow, single; and *Zéphirine Drouhin* (*H.B.*), silvery-pink, semi-double.

TALLER HEDGES.—These require to be trained to wires strained between stout posts. Varieties suitable are the AYRSHIRES, HYBRID WICHURAIANAS, and RAMBLERS, which are described in the article on *ROSE CLASSES*.

Roses for Pegging-down.—Where space allows, many Roses of vigorous habit, making long shoots, can be pegged down instead of being pruned back. Thus treated, they bloom along their entire length, and are wonderfully decorative. At the end of the season the growths that have bloomed are cut away, and the new shoots are bent back carefully and secured in their place. Among those that lend themselves to this treatment are the following:—

Avoca (*H.T.*); *Frau Karl Druschki* (*H.P.*); *General Jacqueminot* (*H.P.*);

Gloire Lyonnaise (*H.T.*); *Gruss an Teplitz* (*H.T.*); *Gustave Régis* (*H.T.*); *Hugh Dickson* (*H.P.*); *J. B. Clark* (*H.T.*); *Juliet* (*P.*); *La France* (*H.T.*); *Madame Isaac Periere* (Bourbon); *Madame Jules Gravereux* (*T.*); *Mrs Stewart Clark* (*H.T.*); *Ulrich Brunner* (*H.P.*); *Zéphirine Drouhin* (*H.B.*).

Roses for Pillars.—For this purpose the Hybrid Bourbons, Hybrid Teas, Noisettes, Ramblers, Teas, and Wichuraianas recommended under ROSES FOR ARBOURS, ARCHES AND PERGOLAS are suitable; but as pillars are not necessarily so tall other varieties are also available. It is not possible in the space at command to give more than a selection, and as many of them are referred to in other paragraphs or in the article on *ROSE CLASSES*, the colours are not repeated: *Ards Pillar* (*H.T.*); *Bardou Job* (*H.T.*); *Billard et Barré* (*T.*); *Effective* (*H.T.*); *François Crousse* (*T.*); *Gruss an Teplitz* (*H.T.*); *Gustave Régis* (*H.T.*); *J. B. Clark* (*H.T.*); *Lady Waterlow* (*H.T.*); *Madame Jules Gravereux* (*T.*); *Mrs Rosalie Wrinch* (*H.T.*, single); *Papillon* (*T.*); *Rosette de la Légion d'Honneur* (*H.T.*); *Waltham Climber* (*H.T.*).

Roses for Walls.—The fact that a Rose is of so-called climbing habit does not necessarily imply that it is suitable for growing on a wall or close fence, such positions being often too warm, while preventing the free exposure of the growths to air and sun. Others, however, are not so particular, or by reason of being more or less tender should have a warm south or west wall. There are a few Roses that will thrive on cool east and north walls, and a selection of each follows :—

CLIMBERS FOR COLDER POSITIONS. —*Ayrshire Roses*; *Bouquet d'Or* (*DIJON T.*); *Climbing Caroline Testout* (*H.T.*); *Climbing Mrs W. J. Grant* (*H.T.*); *Félecité et Perpétue* (sempervirens, creamy-white); *Gerbe Rose* (*W.*); *Gloire de Dijon* (*T.*); *Longworth Rambler* (*H.T.*); *Madame Alfred Carrière* (*N.*); *René André* (*W.*); *Ruby Queen* (*W.*).

CLIMBERS FOR WARM WALLS.—*Banksian Roses* (white and yellow); *Bardou Job* (*H.T.*); *Billard et Barré* (*T.*); *Climbing Aimée Vibert* (*N.*); *Climbing Liberty* (*H.T.*); *Climbing Mrs W. J. Grant* (*H.T.*); *Climbing Papa Gontier* (*H.T.*); *Climbing Richmond* (*H.T.*); *Climbing Souvenir de la Malmaison* (*H.B.*); *Fortune's Yellow* (*N.*); *François Crousse* (*T.*); *Lady Waterlow* (*H.T.*); *Lamarque* (*N.*); *Longworth Rambler* (*H.T.*); *Madame Alfred Carrière* (*N.*); *Madame Berard* (*T.*); *Madame Jules Gravereux* (*T.*); *Rêve d'Or* (*N.*); *sinica* (species, white); *sinica Anemone* (hybrid of species, rosy-pink); *W. A. Richardson* (*N.*); *Zéphirine Drouhin* (*H.B.*).

To conclude, we give selections of Evergreen Roses and Single Roses, as both these are very popular in some districts :—

Evergreen Roses. — Evergreen Roses are few in number, if we exclude the Wichuraianas, which sometimes carry the old foliage through until the new leaves are out. But this depends on the character of the winter and the situation where they are grown. *Dorothy Perkins*, *Gardenia*, *Joseph Billard*, *Lady Gay*, and *Robert Craig* may be cited as almost evergreen, while *Edmund Proust* and *Jersey Beauty* are even more persistent. At one time there were several varieties of *Rosa sempervirens*, the EVERGREEN ROSE, in cultivation, but they are now practically unknown, three only surviving, namely :—

Félicité et Perpétue. — Creamy-white flowers.

Flora.—Bright rose flowers.

La Guirlande.—Almost pure white flowers.

The AYRSHIRE ROSES (see article on *ROSE CLASSES*) are also evergreen under ordinary conditions, *i.e.*, except in severe winters; and at least one Tea, *Madame Antoine Mari* (blush-white), is characterised by being nearly evergreen. In sheltered places many of the ordinary Roses retain their foliage almost through the winter.

Single Roses.—The Wichuraianas and Climbing Polyanthas have many varieties bearing single flowers; Hybrid Sweet Briars and various species are also single or semi-double; but there is a class of single-flowered Roses which has achieved great popularity in recent years, alike for their usefulness in the garden, and for indoor decoration, in which their lightness is a strong recommendation. Some of them have more than a single row of petals. Among the best may be mentioned :—

Gottfried Keller (*P.*).—Deep yellow and pink flowers.

Irish Beauty (*H.T.*).—Pure white flowers.

Irish Elegance (*H.T.*).—Bronzy-orange in bud, but opens to apricot.

Irish Fireflame (*H.T.*).—Fiery-orange, but opens to pale pink.

Irish Glory (*H.T.*).—Deep red flowers.

Isobel (*H.T.*). — Carmine-red flowers with copper shading.

Mrs Rosalie Wrinch (*H.T.*).—Deep salmon-pink flowers.

Paul's Single White (*H.P.*).—White flowers.

Princess Mary (*H.T.*).—Scarlet-crimson flowers.

Red Letter Day (*H.T.*).—Deep scarlet crimson flowers.

Simplicity (*H.T.*).—Pure white flowers.—W. J. C.

ROSES FOR BEDDING.—See *ROSES FOR ALL PURPOSES*.

ROSES FOR CITY GARDENS.—See *TOWN AND CITY GARDENING*.

ROSES FOR EXHIBITION.— See *ROSES FOR ALL PURPOSES*.

ROSES : PLANTING.— See *ROSE PLANTING*.

ROSES : PRUNING. — See *PRUNING ROSES* and *SHRUBS*.

ROSES : SINGLE.—See *ROSES FOR ALL PURPOSES*.

ROSES : TOP-DRESSING FOR. — See *TOP-DRESSING*.

ROSETTE COLEWORT.—See *COLEWORT*.

ROSETTE MULLEIN.— See *RAMONDIA*.

ROSIN WEED.—See *SILPHIUM*.

ROSMARINUS.—For the best species see *SHRUBS*.

ROTATION IN THE FLOWER GARDEN. — As a general rule rotation, such as should be practised in the vegetable or kitchen garden, is quite impossible among the flowers. Herbaceous borders are made and planted, and have to last for years, and even when lifting and replanting is done very often it is necessary that the same plants should occupy the same positions. And does it matter? No, not much, perhaps comparatively little, but then we overrule the need for rotation by heavy manuring from time to time and by frequent top-dressings and feeding.

It does happen at times, however, that a plant ceases to do well in any particular position, and here comes in the need for a little rotational work. Study the plant first. Has it a leguminous root, namely, a root with little nitrogen-containing nodules on it? If so, plant it in a site not previously occupied by any similar or leguminous plant. Has it a long tap-root? If so, plant it in ground previously occupied by a surface and fibrous-rooted flower, or *vice versa*. As a general rule,

where sickness of this kind is noticed, plants of any one natural order should not be planted in ground immediately occupied previously by plants of the same order; but as the natural orders (which are always given in the plant articles in this work) contain plants of very varying characteristics, this rule must not be made "a law of the Medes and Persians which altereth not." Common sense and judgment should be used in this, as in every other operation in gardening.

In the case of annuals and summer bedding plants rotation is quite easy, and, though not essential, is exceedingly advisable, more especially if manure and liquid food have to be economically used. Plants of different natural orders, and plants with different characteristics take different food materials from the soil, thus subjects making much foliage will rob the ground of most of its nitrogen; subjects flowering quickly which are soon over will rob their sites of most of the phosphates they contain; the subjects blooming for a very long period, and producing flowers of high quality and in large quantity will take out of the soil a good portion of the potash it contains. Very often an annual, rooting near the surface of the soil, will decline in flower production year by year, until it is a total failure, whereas if one of the same natural order, but with long tap-roots, is sown, it will be a crowning success for several years. In other words, the surface soil may be totally devoid of the food required by that plant, and yet the under-soil be full to overflowing with it.

The above will serve to show that while no definite hard-and-fast rules for flower garden rotation can be laid down, the general principles of rotation will, if applied to the flower garden as well as the vegetable plot, give increased returns and far more successful results. Sickness of plants is to a large extent avoidable in the writer's opinion, if plants, their families, and requirements are studied from the point of view of rotation.—E.

ROTATION OF CROPS; AND DOUBLE CROPPING. — Rotational cropping is a system in which vegetables of the same character or those closely related in some way do not follow one another on the same piece of ground year after year. For instance, certain plants root deeply while others have fibrous surface roots, so that by alternating, say, carrots and lettuces we utilise to the utmost the manurial substances in the ground. As is well known, too, plants of one family such as the cabbage and turnip group, take a lot of one or two plant foods from the soil, while others such as onions need those foods scarcely touched by the former; less manure and more economical cropping are thus the direct results of applying the principle of rotation in these cases. The pea and bean family, on the other hand, actually enrich the soil in some respects, and thus make it fit to yield large and profitable quantities of cabbages and lettuces, while there are many garden crops that need lavish supplies of farmyard manure, such as leeks and potatoes, that can be followed by those merely requiring a rich soil without fresh manure, *e.g.* parsnips, beet, etc.

Cropping Rules.—While it must not be forgotten that local conditions may vary the cropping to a certain extent, there are certain fairly hard-and-fast rules for guidance. Beet, carrots, parsnips, and scorzonera, which must not have fresh manure, should follow heavily dunged crops such as cabbages, celery, leeks, lettuces, onions, and turnips, top-

dressings of nitrates being only permissible for these root crops when they are young. Cabbages and turnips may follow beans, celery, leeks, lettuces, onions, peas, or potatoes, as they grow freely in good fresh soil heavily manured. Broad beans, French beans, peas, and so on do splendidly in ground previously occupied by celery, leeks, lettuces, onions, and potatoes; they love a deeply tilled soil and good manure without much nitrogenous food. Potatoes grow well after almost any crop; they love a loose soil well manured. Strawberries, hardy perennials, roses, fruit bushes, asparagus, and long-standing crops do best in a soil which has borne a few crops of beans, lettuces, or potatoes.

THREE YEAR ROTATION. — The garden is divided, mentally or practically, into three plots, in each of which are grown different groups of plants, as in the following table:

First Year.	Second Year.	Third Year.
Plot 1 . . Group A	Group B	Group C
Plot 2 . . ,, B	,, C	,, A
Plot 3 . . ,, C	,, A	,, B

FOUR YEAR ROTATION.—The garden is here divided mentally into four plots, and different crops are raised annually on them as follows:—

First Year.	Second Year.	Third Year.	Fourth Year.
Plot 1 . Group D	Group E	Group F	Group G
,, 2 . ,, G	,, D	,, E	,, F
,, 3 . ,, F	,, G	,, D	,, E
,, 4 . ,, E	,, F	,, G	,, D

Rotational Cropping. — Rotation systems are the results of wide experience and practical reasoning. Every gardener must work out his own system and he will soon reap the benefit of good systematic work in healthy plants, free from pests or weeds, and the keeping of the soil fertility at a good average standard. We give here two of the best rotations, and readers should model their own systems on these, varying the procedure according to their local climate, soil, manure available, and kitchen requirements.

CROPPING GROUPS.—In the above two tables *Group A* consists mainly of broad beans, cabbages, French beans, kohl rabi, peas, runner beans, swedes and turnips.

Group B consists of beet, carrots, celery, leeks, lettuces, onions, parsley, and parsnips.

Group C consists of potatoes only.

Group D also consists of potatoes only.

Group E consists of peas and all kinds of beans, as well as celery, leeks, lettuces, and onions.

Group F consists of beet, carrots, parsnips, salsafy, and scorzonera without any manure, with parsley, shallots, and any seedlings to be transplanted; while

Group G consists of cabbages, cauliflowers, kohl rabi, lettuces, savoys, spinach, swedes and turnips.

Double Cropping or Successional Cropping.—As soon as one crop is cleared from a piece of ground another should be planted out in the same ground, especially in the case

of such crops as early potatoes, peas, cabbages, spring onions, early turnips, or those which have occupied the ground over winter and mature early in the season. The ground merely needs to be lightly forked over (but even this will be unnecessary in the case of early potatoes), and raked level as soon as the first crop has been cleared off. A heavy manuring for the first crop and a judicious rotational system such as already described is advisable, but double cropping will not entail a fresh application of farmyard manure for the second crop, though in a starved light soil this is often advisable. The ideal method is to apply a light dressing of artificials to urge on the second crop, though even this is not essential.

As regards examples of this kind we may mention that any crop may follow early potatoes; after peas, we can plant lettuces, spinach, intermediate or shorthorn carrots, winter broccoli, early kale, early turnips, swedes, or purple-top turnips, winter leeks, etc.; while after cabbages any crop save turnips or other members of the Brassicæ may be successfully planted. The idea is obvious—to snatch from the soil before the winter some crop which matures in a short space of time. As a place must be found in every garden for transplanting Wallflowers, Canterbury Bells, Sweet Williams, seedling perennials, violas, pansies, or summer cuttings of pinks, carnations, and other plants, the vacant area will be just in time for this; they can be left here until the end of autumn or spring, when they will, of course, be transplanted into their flowering sites.

A little forethought may even secure a third crop annually from one piece of ground, *e.g.* early potatoes, lettuces, spring-maturing broccoli; early peas, spinach, spring cabbages; peas, shorthorn carrots, and spring cabbages; winter broccoli, carrots, viola seedlings, and so on; each of the three planted in succession.

In a few instances one crop may be planted before the other is actually lifted. Instances of this may be given where brussels sprouts, savoys, and kale are dibbed in between rows of early potatoes; the potatoes are lifted and the Brassicæ left to grow on. Spinach, leeks, vegetable marrows, and swedes may be sown or planted alongside early peas; when the pea haulm is removed they can have space to mature, nor do they resent the shade as seedlings. French beans, runner beans, vegetable marrows, and leeks may be planted in the cabbage patch before the cabbages are mature, provided, of course, that they are not too close; instead of being checked these plants will actually thrive under the leafy wings of the cabbages, and when they begin to develop the cabbages will be in demand.

Lastly, a good garden is far too valuable to leave vacant for even a week or two. If no plants are ready, sow the area down with rape, mustard, rye-grass, comfrey, or any cheap seed producing soft leafy herbage (see article on *Green Manuring*); dig the plants in just before the rigours of winter, thus conserving the manurial elements already in the soil, adding to the store and materially bettering the physical condition of the ground. With good tillage, liberal manuring, and, above all, organisation, a keen gardener may easily double or treble the weight of his garden produce.

H. H. A.

ROWAN (*Pyrus Aucuparia*) and **ROWAN TREE** (*Pyrus Aucuparia*). See *TREES*.

ROYAL FERN (*Osmunda regalis*).—See *FERNS AND FERN GARDENING*.

ROYAL PALM (*Oreodoxa regia*).—See *PALMS*.

RUBBISH.—See *BURNING GARDEN RUBBISH*.

RUBIA (MADDER. Nat. Ord. Rubiaceæ).—This is a genus chiefly of hardy herbaceous perennials none of which are of any value for British gardens though of very easy culture. *R. peregrina*, the WILD MADDER, is probably the best known, though *R. tinctorum*, the DYER'S MADDER, is more useful. *R. cordifolia* (Syns. *R. alata* and *R. chinensis*), as well as *R. sikkimensis*, are sometimes grown. They mostly bear yellow or whitish flowers in July, and average 1–4 ft. in height.

RUBUS.— For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

RUDBECKIA (CONE-FLOWER. Nat. Ord. Compositæ). — This is a well-known genus of beautiful hardy perennial border plants suitable alike for mixed flower borders, for shrub borders, and margins to the wild garden. The flowers are deservedly most highly prized for cutting in the late summer and autumn, especially those of *R. laciniata*. Some of the species which used to be included in the genus now occupy positions in other genera, such as *Echinacea*, *Helenium*, and *Lepachys*. Articles on the first two appear in their proper place, but as the species of the last-named are quite unimportant they are excluded from the present edition of this work.

Culture of Rudbeckias, or CONE-FLOWERS, as they are popularly termed, is a matter of extreme ease. They do well in ordinary garden soil, and once planted will spread quite quickly. It is desirable to lift and divide the clumps once in three or four years, and as some of them grow very tall, prompt and efficient staking is necessary. Propagation alike by seeds sown in the summer, or by root division from October to March, is remarkably easy, and planting may be carried out with every prospect of success from November to early April.

What to Grow.—We recommend the following species :—

Rudbeckia amplexicaulis (Syn. *R. amplexifolia*).—This is a very useful yellow sort blooming in July and August, which averages about 1 yd. in height.

R. bicolor.—This is a useful pale yellow sort, with an outer circle of brown. It blooms from July to August, and grows 1½–3 ft. in height.

R. digitata.—Syn. *R. laciniata angustifolia*, which see.

R. grandiflora.—This bears large yellow flowers from July to September, and grows 2–4 ft. high.

R. laciniata.—This is probably the most popular species of all, with its large yellow flowers in August and September, on plants often over 6 ft. high. There are several good varieties of it ; for instance, *angustifolia* (Syn. *R. digitata*) is a robust form with golden-yellow flowers ; *flora plena* is a fine double yellow, and

Golden Glow needs no description, save that it is worthy of its name. All these bloom with remarkable freedom from August to September, and average 6 ft. in height.

R. maxima.—This is the tallest sort of all, and more suitable for shrub borders or the wild garden than anywhere else. It produces light lemon-yellow flowers in August and September, and grows 6–10 ft. in height.

R. Newmani.—This sort so often offered by nurserymen as a distinct species is synonymous with *R. speciosa* below.

R. speciosa (Syn. *R. Newmani*).—This is a deservedly popular species bearing large bright golden-yellow flowers surrounded by an almost black zone, from June to October. Many fanciful names such as BLACK-EYED SUSAN have been applied to this plant, which grows 2–5 ft. in height.

RUE.—The genus RUTA or *R. graveolens.* See *POTHERBS, RUTA,* and *SHRUBS.*

RUE ANEMONE (*Thalictrum anemonoides*).—See *THALICTRUM.*

RUGOSA ROSES.—See *ROSE CLASSES.*

RUM CHERRY (*Prunus serotina*).—See *TREES.*

RUMEX (DOCK. Nat. Ord. Polygonaceæ).—Most of the members of this genus are weeds of no value, but of a very troublesome nature in the garden, needing most careful taking out on account of their long roots. Thus we have *R. Acetosella,* the SHEEP SORREL; *R. alpinus,* the MONK'S RHUBARB; *R. Hydrolapathum* (Syn. *R. aquaticus*), the GREAT WATER DOCK; *R. hymenosepalus,* the WILD PIE PLANT; *R. maritimus,* the GOLDEN DOCK; *R. obtusifolius,* the BUTTER DOCK; *R. Patientia* (Syn. *R. olympicus*), the PATIENCE DOCK; *R. pulcher,* the FIDDLE DOCK; *R. sanguineus,* the well-known BLOODWORT; *R. scutatus,* the FRENCH SORREL; and *R. vesicarius,* the BLADDER DOCK. Some of these have medicinal value; for these see article on *MEDICINAL HERBS.* The most useful species is *R. Acetosa,* the COMMON SORREL, or SORREL, sometimes grown as a vegetable, as described in our article on *SORREL.*

RUNNER BEANS.—See *BEANS.*

RUNNER BEANS IN SALT.—See *VEGETABLE BOTTLING.*

RUNNING MUTISIA (*Mutisia decurrens*). — See *CLIMBING AND TRAILING PLANTS.*

RUNNING OAK (*Quercus pumila*). — See *TREES.*

"RUNNING OFF" IN BLACK CURRANT.—See under REVERSION IN BLACK CURRANT in *DISEASES OF PLANTS.*

RUSH.—See *JUNCUS.*

RUSH-LEAVED DAFFODIL (*Narcissus juncifolius*).—See *NARCISSUS SPECIES.*

RUSSIAN ALMOND (*Prunus nana*).—See *TREES.*

RUST FUNGI.

The Rust Fungi, scientifically known as the Uredineæ, consist of a large group of parasitic fungi which attack all classes of plants, and sometimes cause considerable damage. The fungi themselves are minute, and live within the tissue of their host-plants, but produce sori or clusters of yellow or brown spores, which, as they occur in great profusion, often give a yellow or brown appearance to the plants. Hence the term "Rust Fungi." In ordinary garden *parlance* the word "rust" is used loosely to describe almost any brown discoloration due to any cause, but it is advisable to limit the term to diseases produced by the true Rust Fungi or Uredineæ. Examples of these are the rusts of Asparagus, Bean, Black Currant, Carnation, Chrysanthemum, Hollyhock, Mint, Rose, and Violet.

The life-history of the Uredineæ is rather complicated, since many of them possess different spore-stages which follow each other in regular succession. In the most highly organised, four spore-forms are present, but in others two or three only occur, and in some one only is known. When the full sequence is present the first form is the *Aecidiospore* or cluster-cup stage, where the spores, usually golden in colour, are arranged in minute cups. These are produced mostly in spring, *e.g.* Anemone and Mint Rust. This is followed by the *Uredo*, or summer-spore stage, which is often very destructive, the spores being produced in great profusion and spreading the disease rapidly. Later comes the resting or *Teleutospore* phase, which consists typically of thick-walled resting spores which lie dormant till spring, when they germinate on dead leaves or on the ground, and give rise to other spores (*Basidiospores*) from which the cluster-cup stage is produced.

A further complication lies in the fact that rust fungi are sometimes heteroecious, that is, they require two hosts to complete their life-history. In the Pear Cluster-Cup, for instance, the *Aecidial* stage is on the Pear, but the *Teleutospore* stage exists on the Juniper. As a rule, the mycelium is localised, and a very large number of separate infections occur on any one plant, in which case it is usually annual, and the mycelium itself, though not the resting spores, dies with the leaf-fall in autumn, *e.g.* Hollyhock or Chrysanthemum Rust. In other cases the mycelium is distributed right through the plant, and in this case is usually perennial, *e.g.* Mint Rust.

Means of Control.—It will be obvious from the above that the only way intelligently to combat the rust fungi is to ascertain the outline of the life-cycle. Information as to this is indicated under each species dealt with in this work. When the life-cycle is understood, common sense will largely suggest the most successful methods of control.—A. D. C.

RUSTIC FURNITURE.— See *GARDEN FURNITURE*.

RUTA (RUE. Nat. Ord. Rutaceæ).

The members of this genus are herbs of no value for the ordinary garden, but useful in the herb border. They must not be confused with MEADOW RUES described in our article on *THALICTRUM* which are highly attractive foliage and flowering plants for perennial parterres. There are various species, such as *R. bracteosa*, SICILIAN RUE, and *R. patavina*, the PADUA RUE. The most useful is, however, *R. graveolens*, the COMMON RUE, or known just as RUE, under which name a few remarks on its culture will be found in our article on *POTHERBS*.

See also *SHRUBS*.

RYE.—See *SECALE*.

RYE GRASS.—The popular name of *LOLIUM*, which see.

RYE GRASS, ITALIAN (*Lolium multiflorum*).—See *LOLIUM*.

S

SACCOLABIUM.—See article on *ORCHIDS.*

SACRED FIR (*Abies religiosa*).—See *TREES.*

SAFFLOWER (*Carthamus tinctorius*). See *CARTHAMUS.*

SAFFRON, MEADOW. — A name applied to the genus *COLCHICUM.* Culture is given under CROCUS, AUTUMN, in *MEDICINAL HERBS.*

SAGE (*Salvia officinalis*).—See *POT-HERBS* and *SALVIA.*

SAGE-BUSH (*Artemisia procera*).—See *SHRUBS.*

SAGE WILLOW (*Salix candida*).—See *TREES.*

SAGENIA.—Now included in the genus NEPHRODIUM. See *FERNS AND FERN GARDENING.*

SAGHALIEN FIR (*Abies sachalinensis*). See *TREES.*

SAGINA (PEARL-WORT. Nat. Ord. Caryophyllaceæ).—This is a genus of dwarf-growing annual weeds of no value for the garden.

SAGITTARIA (ARROW-HEAD. Nat. Ord. Alismaceæ).—This is a genus of greenhouse, hardy, and stove water plants. The first and the last sections are excluded from the present edition as being beyond its scope. The best hardy species are described under ARROW-HEAD in our article on *WATER GARDEN: PLANTS FOR THE,* to which readers are referred.

ST. ANTHONY'S TURNIP (*Ranunculus bulbosus*).—See note at end of *RANUNCULUS.*

ST. BERNARD'S LILY (*Anthericum.* Nat. Ord. Liliaceæ). — Unless we still include St. Bruno's Lily, which used to be put in the same genus as St. Bernard's Lily under Anthericum, there is only one species of sufficient garden utility to be included in this work. The genus consists of tuberous-rooted herbaceous perennials usually bearing white flowers.

Culture.—Any good light soil suits the St. Bernard's Lily. It may be planted any time in October or in the early part of November. A mulching of old rotten manure put over the crowns in December is helpful in keeping the plants in vigorous health.

Varieties :—*Anthericum Liliago.*—This bears small white lily-like flowers from June to August. Its height is 1½ ft.

A. Liliastrum.—This is the old botanical name for ST. BRUNO'S LILY, now *Paradisea Liliastrum,* and is mentioned here on account of its similar appearance to St. Bernard's Lily, as it is frequently found under this name in the older gardening works. It blooms in May and June, but is not so tall. See notes on *ST. BRUNO'S LILY.*

Paradisea Liliastrum major. — This, which resembles the above, frequently grows 5–6 ft. high.

J. J. & E. T. E.

ST. BRUNO'S LILY (*Paradisea Liliastrum,* Syn. *Anthericum Liliastrum.* Nat. Ord. Liliaceæ).—This is a useful bulbous border plant requiring the same culture as *ST. BERNARD'S LILY,* which see. It bears white flowers in the early summer, and averages about 1½ ft. in height. The sub-variety *P. l. major* bears bigger blooms, and averages 5–6 ft. in height.

ST. DABEOC'S HEATH (*Daboëcia polifolia*).—See *HEATHS* and *SHRUBS.*

ST. JOHN'S WORT.—See *HYPERICUM*, and *WATER GARDEN: PLANTS FOR THE*. See also HYPERICUM in *SHRUBS*.

ST. JOSEPH'S LILY (*Lilium candidum*). See *LILIES*.

ST. LUCIE CHERRY (*Prunus Mahaleb*). See *TREES*.

ST. PETER'S CORN (*Triticum monococcum*).—See *TRITICUM*.

SALAD PLANTS.

In addition to the better known kinds of plants used for salads, such as Lettuces and Radishes, the cultivation of which is fully dealt with in separate articles on these crops, most of the plants enumerated below find favour either in a mixed salad or alone, and even though the cultivation of a large quantity of any of them is not desirable, the inclusion of a few at least of these little known kinds in the garden is bound to make it much more interesting, and also add needed variety to the salad bowl no matter what the season of the year.

Brief cultural hints on these are given below.

Capsicum (*Capsicum annuum*. Nat. Ord. Solanaceæ).—Seed should be sown in moderate heat early in March, and as soon as the plants are large enough to bear pricking out, transfer to shallow boxes filled with a light sandy soil, and keep covered with a sheet of glass until new roots are made. When ready for a small pot, give each a pot to itself, moving into others until the 6-inch size is reached. Equal parts good turfy loam and leaf-soil suit them during the early stages, but when transferring to final pots add to this one-third old hotbed manure. A cold frame is better for the plants than a heated house; liquid manure may be given after the fruit is set.

VARIETIES.—The most popular include:—Cayenne, Coral Gem, Elephant Trunk, Large Red, Large Square, Long Yellow, Tomato-Shaped, and Yellow Cherry.

Chervil (*Anthriscus cerefolium*. Nat. Ord. Umbelliferæ).—This is one of the most useful of the little known salad herbs. Seeds may be sown in nicely broken-up and finely raked-down soil, any time from March until August. For the later sowing none but a warm, dry spot should be chosen, and light protection afforded the rows during the most severe part of the winter. Allow about 12–15 ins. between the rows, and bury the seed with not more than half an inch of soil, thinning out the plants to 6 ins. apart each way.

Chicory (*Cichorium Intybus*. Nat. Ord. Compositæ).—This forms a very useful winter salad. Seed may be sown in any fairly good soil, early in May, allowing 12 ins. between the rows and 9 ins. between the plants. In November lift a portion of the crop, and after twisting off the tops, re-plant in boxes or pots fairly close together, afterwards standing them in a warm cellar or house where complete darkness is assured. Keep the soil fairly moist, also syringe overhead occasionally. The tops are ready for use when about 9 ins. high, and after cutting them throw away the old roots; a constant supply of young growth being maintained by the frequent introduction of successive batches.

Chili (*Capsicum baccatum*. Nat. Ord. Solanaceæ).—This is not widely cultivated, and is rarely used as an addition to mixed salad except in a green state.

Seeds of all varieties require to be sown in a heated greenhouse early in March, the seedlings being pricked out, or potted on until the middle of May, after which they will be better planted out in a garden frame, or in a warm

border. They need a very rich soil and frequent overhead syringing to keep the foliage free from insect pests.

VARIETIES are very numerous: for these reference must be made to trade lists. A comprehensive collection of these is decidedly interesting and attractive.

Chives (*Allium Schoenoprasum.* Nat. Ord. Liliaceæ).—These are very useful plants, more especially where a mild onion flavour is appreciated in the salad bowl, or even as a substitute for young onions in a raw state. They are of easy cultivation, forming compact growing tufts of narrow green leaves, with small bulbs at the root.

Any ordinary garden soil is suitable for their culture, and although not absolutely essential, division of the clumps every third or fourth year is desirable, Planting may be done in early spring, and the cutting of the tops may commence as soon as these are of sufficient length for the purpose wanted. Being of perennial growth, these tops may be cut away several times during the summer, new leaves appearing in a very short time after cutting.

Corn Salad (*Valerianella olitoria.* Nat. Ord. Valerianaceæ).—By many this is better known as *Lamb's Lettuce*, but it is not largely cultivated in this country where the more popular varieties of ordinary Lettuce give better results, especially during the hottest months of summer.

If a summer crop is desired, seed may be sown from early April onward. Frequent sowings are recommended, since the young plants so quickly run to seed. Sowings made in a warm border from the middle of August until the middle of September usually give the most satisfactory returns.

Select a well-manured piece of ground, and sow in drills 6–8 ins. apart, thinning out the seedlings to about 3–4 ins. asunder, and when these carry leaves of fair size, pull up each alternate plant for early use. Picking should be systematically done as soon as the leaves attain fair size, the constant use of the hoe facilitating growth, and prolonging the life of the bed. A light covering of hay should be placed over beds during the most severe weather. If this is done the latest sown plants will give a crop of nice young leaves early the following spring.

Dandelions (*Taraxacum officinale.* Nat. Ord. Compositæ).—These form a useful addition to our winter salads, and deserve to be more widely cultivated.

To obtain good forcing roots, sow seed of the improved variety early in May, allowing a foot between the rows and not less than 8 ins. between the plants. Summer treatment consists of keeping the ground free from weeds. In October or November a portion of the roots should be taken up and treated exactly as advised above for CHICORY.

Egg Plant (AUBERGINE. *Solanum Melongena* var. *ovigerum.* Nat. Ord. Solanaceæ).—Apart from the interesting appearance of these, many find the fruits valuable in mixed salads.

To obtain plants of good size, seed must be sown in a hotbed or in a heated greenhouse early in March, and when the seedlings are 3 ins. high, carefully lift each with a stick, disturbing the roots as little as possible, and pot into small, well-drained pots, using a light, open compost. Keep the plants in a bed covered with glass until new growth is made, afterwards admitting air freely. At each subsequent potting use a rich soil,

making this firm about the roots, and disturbing these as little as possible.

The plants may be fruited in pots, or planted out in a sunny border early in June. If the former is favoured, give manure water at each alternate watering after the fruits are set. Plants in the open border should be mulched with rotten manure immediately the first fruits are set, and all should be kept moderately moist at the root, and during hot weather syringed freely overhead.

Mustard and Cress (*Brassica Sp.* and *Lepidium Sp.* Nat. Ord. Cruciferæ).—The cultivation of this is so well understood by all that only a passing reference need be made to it here.

Seeds germinate much more quickly in the dark than when exposed to full light, and a piece of board or brown paper is far better than fine soil for covering the seed, which last should be pressed firmly into the soil and well watered immediately after sowing.

If wanted for use at the same time as Mustard, Cress should always be sown two days in advance, and if outdoor sowing is attempted, and the seed not covered with wood or brown paper, black cotton must be freely stretched across to keep off sparrows and other birds.

Nasturtium (*Tropaeolum majus* and *minus*. Nat. Ord. Geraniaceæ).—The leaves of the climbing and dwarf Nasturtium are much appreciated by some in salads, or indeed at tea-time, between slices of bread and butter. The young leaves only should be used, since the older ones are too strong, and the plants for these purposes must have copious supplies of water. They are grown in a similar way to other less hardy annuals, outdoor sowings being safely made in May. See the notes on *Nasturtium* in the body of this work for further particulars.

Purslane (*Portulaca oleracea*. Nat. Ord. Portulaceæ).—This plant has almost gone out of cultivation as a salad plant, being very rarely found even in our largest gardens. It is of easy cultivation, and in addition to the value of the leaves as salad, they may also be boiled in the same way as spinach.

Sow the seed any time from April till September, scattering this thinly in rows 6 ins. apart, the seedlings being thinned to the same distance asunder when they are a few inches high.

Watercress (*Nasturtium officinale*. Nat. Ord. Cruciferæ).—To grow really good Watercress, a shallow stream of running water is desirable. A bed of very gritty soil should be provided, into which, early in spring, nice strong shoots about 6 ins. long should be freely dibbled. Beds may also be made during the autumn, but, generally speaking, those made in spring are more satisfactory.

Good Watercress may also be grown in deep trenches prepared as advised in the article on *Celery*. In these the grower may choose between strong shoots or seed, and if the latter course is adopted, and care taken to keep the soil constantly saturated with clear water, good cress should follow throughout the summer and early autumn.

F. R. C.

SALADINGS.—See *Kinds of Crops* and *Salad Plants*.

SALADINGS: Fertilisers for.—See *Feeding Plants*.

SALAL (*Gaultheria Shallon*). — See *Shrubs*.

SAL-AMMONIAC. — See Ammonium Chloride in *Ammonia and Ammonium Compounds*.

SALIX.—See *TREES*.

SALMON-BERRY (*Rubus nutkanus*).—See *SHRUBS*.

SALPICHLÆNA.—Now included in the genus BLECHNUM, for which see *FERNS AND FERN GARDENING*.

SALPIGLOSSIS (Nat. Ord. Solanaceæ).—This is a genus of beautiful half-hardy annuals available in great variety of colours, pencilled in rich tints of yellow, purple, and brownish-red, as sold in mixtures by seedsmen. They are very free flowering, and fine for cutting purposes, also elegant for pot culture. They thrive best when sown in the autumn and early spring in a gentle hotbed or warm house, and will flower freely in the summer and autumn in the greenhouse or conservatory. They will also bloom freely out of doors in a warm, sunny border if treated like bedding Asters. For indoor culture the soil should be rich, light, sandy loam. Temperature required, 40–50° F.

Greenhouse Species :—*Salpiglossis linearis*.—Yellow and purple. Flowers from July to August. Height, 1 ft.

S. sinuata.—Purple. Flowers in July and August. Height, 1 ft. Its variety *straminea* bears red and white flowers, and grows 2 ft. high.

SALSAFY (*Tragopogon porrifolius*. Nat. Ord. Compositæ).—By many, this is better known as the OYSTER PLANT, and thanks to the prevailing customs now adopted by many of our largest horticultural societies of offering prizes for the lesser known vegetables, the cultivation of this is on the up-grade. This being so it is only reasonable to expect that instead of finding only a few isolated rows in large gardens, the merits of Salsafy as a winter vegetable will be fully recognised by the increasingly large number of middle-class amateurs who, after a fair trial, are not likely to allow the plant to be again absent from their gardens.

Cultivation calls for no special skill; ground which will produce shapely Carrots or Parsnips may be relied upon to give good returns with Salsafy. Like all deep-rooting vegetables it prefers a well-trenched or deeply dug soil, free from fresh or recently-dug-in manure, to a shallow, badly worked site, on which a heavy application of new dung has been used.

Specimens of large size and perfect shape usually follow when this crop succeeds Celery, Peas, or Onions for which ample manure was provided the previous season.

Soils of a very hungry nature should have plenty of leaf-soil added at the time of trenching, or old soot strewn over the soil in liberal quantities at the time of digging, and after the plants are well through the soil.

Seed should not be sown before the first week in May, plants from that sown earlier having a tendency to run to seed. Sow in drills from 1 ft. to 15 ins. apart, distributing the large seed very thinly, and afterwards reducing the grass-like seedlings to 10 ins. apart in the row.

Keep the bed free from weeds all summer, and towards the end of the year carefully lift each root with a fork and store between layers of ashes, or if preferred, the crop may remain in the ground to be dug as required during the winter.

Varieties.—The following two are undoubtedly the best:—Giant French, and Sandwich Island Mammoth.

F. R. C.

SALSIFY.—The same as *SALSAFY*, which see.

SALSOLA (SALTWORT. Nat. Ord. Chenopodiaceæ).—This is a genus of salt-loving hardy annuals of little value, but which thrive in light, sandy soil, especially near the coast. The best species is *S. Kali* with flesh-pink flowers. Its white variety *Tragus* may also be grown. Both flower in July, and average 1–2 ft. in height.

SALT.—The meaning of this chemical term is explained in *CHEMISTRY FOR GARDENERS.*

SALT.—See *SOIL FUMIGATING,* and under SODIUM CHLORIDE in *SODA AND SODIUM COMPOUNDS.* See also *WEED KILLERS.*

SALT TREE.—The genus HALIMODENDRON and *H. argenteum.* See *SHRUBS.*

SALTPETRE. — See POTASSIUM NITRATE in *POTASH AND POTASSIUM COMPOUNDS.* See also NITRATE OF POTASH under NITROGENOUS MANURES in *MANURES.*

SALTWORT.—See *SALSOLA.*

SALVIA (Nat. Ord. Labiatæ).—This genus includes many species of hardy and greenhouse plants, mostly perennials, but some of the greenhouse varieties are best when treated as annuals. Propagation is best effected by seed or by cuttings. The height of the various species averages 1½–6 ft.

Culture.—Sow seed of the GREENHOUSE SPECIES in the early spring in a warm house, and prick out the young plants as soon as large enough to handle. They should not be allowed to become pot-bound, consequently, several changes into larger pots will be necessary till finally accommodated in their flowering quarters, pots of 8-inch diameter being suitable for most of the greenhouse varieties. Cuttings may be taken in spring, and should be kept close in a warm house to ensure quick rooting. For pot culture the compost should be four parts yellow, fibrous loam, one part each of leaf-mould and old manure, with a little silver sand.

USES.—Owing to the brilliancy of their colouring, *S. splendens* and its varieties are extremely decorative for summer bedding, as is also the glorious blue sort *S. patens.* For this purpose they are best raised and treated as half-hardy annuals. The shrubby species are sometimes planted out, but several of them are not very floriferous. For greenhouse decoration both the scarlet and blue types are invaluable. *Salvia officinalis* is the common SAGE, more useful in the kitchen garden than the flower border. Most of the Salvias flower during the late summer and throughout the autumn.

Varieties.—The best for Greenhouse and Bedding purposes are *patens, splendens, tricolor,* and *tubiflora.*—J. L. G.

SALVIA: Biennial Border Species.—These require the usual treatment for biennials, and may be successfully raised from seeds sown in May or June in a cold frame or outside. The seedlings should be transplanted into nursery beds when they have made a few leaves, and later on planted out permanently in sunny positions. We recommend the following:—

Salvia bicolor.—This bears rather attractive flowers, the upper lip of which is bluish-violet, while the lower one is whitish. It blooms from June onwards, and grows 2–3 ft. high.

S. Columbariae.—This bears lovely bright sky-blue flowers in June, July, and August, and grows 1–2 ft. high.

S. Sclarea (CLARY).—This is a useful herb for the kitchen garden, bearing bluish-white flowers in August, and growing 3–4½ ft. high. (See article on *POTHERBS.*)

Perennial Border Species.—These may be grown in the usual way for hardy perennials, but they are not as attractive as some. They are easily propagated by seed and division at the usual times, and are best planted in March. We recommend the following :—

Salvia argentea.—This sort bears pinkish-white flowers from June onwards, and grows 1 yd. high.

S. glutinosa (JUPITER'S DISTAFF). —This is yellow. It blooms from June to July, and grows about 3 ft. high.

S. grandiflora.—This is an attractive blue June and July blooming species, about half the height of *S. glutinosa.*

S. hians (CASHMERE SAGE).—This is a blue June blooming sort growing about 1 ft. high.

S. nubicola.—This is an attractive yellow sort blooming in September and October. Its height averages about 1 yd.

S. nutans.—This bears violet or violet-purple flowers in June and July on plants 2 ft. high.

S. officinalis. See SAGE in article on *POTHERBS.*

S. pratensis (MEADOW SAGE).—This and its variety *Baumgartenii* bear violet and purplish-blue flowers respectively from May to September, on plants 3–4 ft. high.

S. sylvestris (WOOD SAGE).—This must be carefully distinguished from the WOOD SAGE (*Teucrium Scorodonia*) described in our article on *POTHERBS.* It bears violet-purple flowers from August onwards, and averages about 1½ ft. in height.

S. Verbenaca (VERVAIN SAGE).—This and its variety *rubella* bear violet and purplish-red flowers respectively in August and September, on plants 1½–2 ft. high.

S. verticillata.—This bears pretty blue flowers in July and August, on plants 1 yd. high.

S. virgata.—This violet-blue sort blooms in September, and grows 2–3 ft. high.

NEW VARIETY.

Salvia Warleyensis. — This has large heart-shaped leaves and deep violet flowers, with black calyx and stems.

SAMBUCUS.—See *TREES.* See also under ELDER in *MEDICINAL HERBS.*

SAMPHIRE (*Crithmum maritimum.* Nat. Ord. Umbelliferæ).—This is used as a pickling plant, and is quite hardy. It bears white flowers from July to August, and grows about 12 ins. high.

Culture is easy in a light, rich spot which does not get very much sun. Seed may be sown outside in March and April, or roots may be purchased and planted in the first named month. Frequent hoeing and watering are advisable, also gentle feeding with salt or nitrate of soda.

SAND.

There are many kinds of sand which are useful to the gardener. We name a few of the more important below :—

Builders' Yellow Sand. — This is not much use for potting, but very good as a medium for plunging plants in. Freshly potted bulbs may in the autumn be buried under 18 ins. of it to keep them warm and induce them to start growing. Plants can also be stood in a bed of it out of doors, or plunged just up to the rims of their pots in it, but it is not quite so good for this purpose as are fine coke ashes ; it is not gritty enough to stop worms completely from entering the pots. Roots such as beet, carrots, celery, leeks, parsnips, and salsafy can be buried in a good bed of it when they have been dug up in the

autumn, and will store with perfect safety thus. The yellow sand is also useful for putting on the garden paths in frosty weather to prevent garden owners from slipping, and possibly breaking their necks.

River Sand is frequently a very fine material. In some cases it is quite rich in plant food. It can be used for digging into stony soils, or, when it is rich silt, for improving light soils. In some places it is impossible to get. If it is almost pure sand it may be used for the same purposes as builders' sand named above.

Road Sand is a material of variable quality. When the roads are made of soft sandstone a dust similar to dry river sand is produced. When they are made of limestone the dust is almost equivalent to ground chalk, and very useful indeed if dug into rich soils which have been heavily manured for years with dung. Probably the richest material is produced in wet winters on granite-stoned roads over which many heavy vehicles pass. As is well known, granite is rich in silicate of lime and potash, and when this is subjected to the action of rain, frost, and snow, the pounding grind of heavy wheels, and the action of the manure dropped by numerous horses, it breaks up into simpler compounds which are much more useful for plant life.

The gardener should buy this material as it is periodically swept or scraped off, allow it to dry, and then use it for digging in. Road sand of any kind can be used very advantageously when trenching a strong heavy clay soil. It has not the irritant and disastrous effect on tubers that coke ashes have (see *ASHES: Their Value in the Garden*). Road sand in summer is often very undesirable material, if not dangerous to health. Diphtheria, consumption, and many other similar germs abound in it, owing to indiscriminate spitting, so the gardener should not get any of the sand then. Road sand cannot be used for potting, nor should it be used for storing roots.

Sea Sand.—This is usually somewhat salty. It is good for working into strong soils for the culture of salt-loving plants, such as asparagus, cabbages, and seakale, or for roots such as beet, carrots, parsnips, and salsafy. But if it has to be used instead of road or river sand for lightening soils it should first be soaked with water. A barrel is used for doing this. The sand is shot in, and water poured over it, stirring constantly. The sand is allowed to settle and the water drawn off. It is advisable then to repeat the process a second time.

Silver Sand is probably by far the most generally useful of all sands for the gardener. It is an essential ingredient of practically every potting soil—essential for seed raising, for cutting striking, and for pricking off seedlings. A good pot of this should always stand on the potting-bench. Some people dip fresh cuttings into the pot of sand prior to inserting them, or shake some of it into the holes for the cuttings. This hastens the formation of roots. Silver sand can also be put in a thin layer over the soil of boxes in which it is desired to sow small delicate seeds of half-hardy and greenhouse annuals, half-hardy perennials, and greenhouse perennials. This induces quick germination.

Silver sand when pure should be white, sharp, and gritty. The "fine" silver sand, often adulterated with poisonous materials, should never be used unless the gardener wants to lose his plants.—E. T. E.

See also *SOILS: THEIR ORIGIN AND NATURE.*

SAND CHERRY (*Prunus Besseyi* and *P. pumila*).—See *TREES*.

SAND MYRTLE.—The genus LEIOPHYLLUM. See *SHRUBS*.

SAND PEAR (*Pyrus sinensis*).—See *TREES*.

SAND PINK (*Dianthus arenarius*).—See *DIANTHUS*.

SAND PLUM (*Prunus Watsoni*).—See *TREES*.

SANDSTONE.—See *ROCKWORK*.

SANDWORT.—See *ARENARIA*.

SANDY SOILS: IMPROVING.—See *SOIL IMPROVEMENT*.

SANGUISORBA.—A synonym for *POTERIUM*, which see.

SANICLE.—See *MEDICINAL HERBS* and *SANICULA*.

SANICULA (SANICLE. Nat. Ord. Umbelliferæ). — One species of this genus, *S. europaea*, also known as WOOD SANICLE, with white flower-heads, is sometimes grown in the herbaceous border, though it is hardly worth this attention. (See article on *MEDICINAL HERBS* under SANICLE, for additional notes on the plant.)

SANTA LUCIA FIR (*Abies bracteata*). See *TREES*.

SANTOLINA (LAVENDER COTTON. Nat. Ord. Compositæ).—This is a useful genus of hardy, shrubby perennials, some of the species of which are now included in *ANTHEMIS* (which see) and other genera. It is of very easy culture, succeeding well under ordinary border or rock garden cultivation, and may be propagated by cuttings in September or March. The best time to plant is from November to February.

What to Grow.—Only a few species are of any great importance. Of these we recommend the following:—

Santolina canescens.—Syn. *S. rosmarinifolia*, which see.

S. Chamaecyparissus. — This is probably the most popular sort of all, with its several varieties. All bear yellow flowers from July to August, and average 2 ft. in height.

S. rosmarinifolia (Syn. *S. canescens*).—This is a useful sort bearing yellow flowers in August and September. It grows about 2½ ft. high.

S. viridis.—This bears yellow flowers in July and August, but only grows 1–2 ft. high.

SANVITALIA (Nat. Ord. Compositæ).—The one useful hardy annual species of this genus is a lovely trailing or spreading plant which comes from Mexico. This, *Sanvitalia procumbens* (Syns. *S. acinifolia* and *S. villosa*), rarely exceeds 6–8 ins. in height, and the garden variety known as *Little Gem* is very dwarf. There are double as well as single forms, but all are free-flowering, and the dark-centred, yellow flower-heads, produced from July onwards, make them effective subjects for edgings or for grouping in the rock garden or flower border. They love sunshine, and should be sown in the spring or early autumn, and transplanted to their flowering positions, or they may be raised in March in gentle heat.

SAP WARTS.—See INTUMESCENCES in *DISEASES OF PLANTS*.

SAPONARIA (SOAPWORT. Nat. Ord. Caryophyllaceæ).—This is a very important genus from the practical gardener's point of view, containing as it does a number of annual, perennial border, and rock garden species. It derives its name from the fact that the juice of the COMMON SOAPWORT (*Saponaria officinalis*) will make a lather with water.

Annual Species.—The two hardy annual species described below are worthy of extensive cultivation. They are easily raised from seeds sown in April and September;

the two sowings are desirable for prolonging the flowering period. The autumn sowings flower in spring, and the spring sowings in early summer.

Saponaria calabrica (Syn. *S. multiflora*).—This is of tufted habit, and white or rosy-carmine varieties are obtainable. Both bloom freely throughout the summer, and grow 4 ins. high. They are suitable for the rock garden, for edging, and massing, if thinned to 4 ins. apart each way.

S. Vaccaria (Syns. *S. hispanica, S. oxyodonta, S. pentagona, S. perfoliata, S. rubra,* and *S. segetalis*).—This is a useful border plant, and quite valuable for cutting for flower decorations. It has rose-pink flowers, but there is also a white-flowered variety. The seedlings should be thinned to 2 ft. apart each way as the plants grow bushy and often attain nearly 1 yd. in height.

Perennial Border Species.—These are useful border or edging plants, chiefly the latter, of easy culture, succeeding in ordinary light soil in a sunny or lightly shaded site. They may be propagated by seeds sown in a frame in the spring or summer, by cuttings of the young growth pegged into sandy soil in a frame after flowering, or by division of the roots in the autumn or spring. Success may be expected by planting them from October to April. We recommend the following :—

Saponaria Boissieri.—A useful species for edging, with pink flowers onwards from June, and growing 3 ins. high.

S. lutea.—This is another useful edging sort bearing pink flowers in July. It grows 3 ins. high.

S. officinalis (Common Soapwort).—The double variety of this (*flore pleno*) is better than the single. Both are attractive pink July flowering subjects useful for cutting, and grow about 2 ft. high. They spread rapidly at the root.

S. pulvinaris.—This is a useful edging species bearing rosy-pink flowers freely through the summer. It grows 3 ins. high.

Rock Garden Species.—The three described below make compact growing plants covered with flowers in early summer. They are propagated by seeds sown in gentle heat in March, or by cuttings in a frame in July.

Saponaria caespitosa.—This is of tufted habit, with narrow leaves. Flowers in umbels, rose coloured. Site sunny. Soil gritty. Flowering Period, June to August. Height, 3 ins.

S. ocymoides.—This sort is of trailing habit with branching stems. Flowers rosy-pink. Site, sunny, rocky ledge. Soil gritty. Flowering Period, May to July. Height, 6 ins. There is a white-flowered form of this plant called *alba.*

S. wienmanniana.—This is a dwarf-tufted plant. Flowers pale rosy-purple. Site, sunny ledge. Soil gritty. Flowering Period, June to July. Height, 3 ins.

SAPONARIA LEAF SPOT.—See *Diseases of Rock Plants.*

SAPROPHYTES.—See *Fungous Diseases.*

SARACEN'S CONSOUND (*Senecio sarracenicus*).—See *Senecio.*

SARCOCHILUS.—See *Orchids.*

SASSAFRAS.—For the best species see *Trees.*

SASSAFRAS TREE.—See the genus Sassafras in *Trees.*

SATIN FLOWER.—See *Sisyrinchium.*

SATIN LEAF (*Heuchera hispida*).—See *Heuchera.*

SATIN POPPYWORT (*Meconopsis Wallichii*).—See *Meconopsis.*

SATUREIA (Savory. Nat. Ord. Labiatæ).—The two species of this genus of hardy plants most usually grown are *S. hortensis,* the

SUMMER SAVORY, and *S. montana*, the WINTER SAVORY. (See SAVORY in our article on *POTHERBS*.)

SAUSSUREA (SAW-WORT. Nat. Ord. Compositæ).—Many species of Serratula are now classed in the present genus, but as the cultural requirements of the two are the same, they are given under the better known *SERRATULA*. Both genera are known by the same English name, but as there are many better things neither should be extensively grown.

Of the species in cultivation, *S. alpina*, *S. candicans*, and *S. hypoleuca* bear purple flowers from June to August. The first grows 6 ins. high, the second 1 yd., and the third 1½ ft. *S. Lappa* and *S. Maximowiczii* bear reddish-purple flowers from June to July, and grow about 12 ins. high.

SAVIN (*Juniperus Sabina*). — See *TREES*.

SAVING SEED.—See *SEED SAVING*.

SAVING SEED POTATOES.

Cooking your hare is conditional on catching him, and saving seed potatoes being dependent on growing them, we shall first say a few words about their production.

Experience has demonstrated the value for "seed" purposes of immature or unripe tubers. The admitted value, to English potato growers, of Scottish or Irish seed is primarily attributable to their comparative immaturity, a result of the heavier rainfall, which makes the tubers longer in growth and fuller of sap than are more ripened ones grown in drier districts. But even in the latter districts, we believe that useful seed tubers can be produced by lifting the crop before the haulm has withered.

As to storing, while much can doubtless be said in favour of greening the tubers and boxing them straight away, we have often been struck by the proportion of apparently sound tubers which has subsequently been destroyed by disease, apparently due to air-developed infection. We therefore prefer to keep potatoes, retained for seed purposes, for a month or six weeks in shallow, earth-covered pits. These are formed in the following manner :—

Pile the tubers either directly on the surface or in a very shallow grave in pyramid form about 2 ft. wide,—the length may be indefinite as there is no risk of heating in such shallow pits,—and having built up the tubers, cover them with about 6–8 ins. of the soil as dry as possible from both sides, forming it into a sharp ridge, and making it firm with the shovel. Finally cover all with a good coating of straw—on no account use the old haulms for the purpose—to keep out rain, placing a ridge of soil over the straw to keep it from being blown off by the wind.

Experience leads us to think that the plain earth in immediate contact with the tubers acts as an antiseptic. Potatoes carrying imperceptible disease spores run considerable risk of ultimate loss if exposed to the air, but, in our opinion, they may be saved by the treatment suggested.

Having completed the pit as described, a shallow drain should be made round it to prevent surface water from reaching the tubers. After remaining in these primary pits for a month or six weeks, it is advisable to open them and re-sort the tubers, putting them either into sprouting boxes, into a store, or into more permanent and larger graves well protected from frost. If boxes are used they should be exposed to the light as much as possible to encourage the growth of plump, tough sprouts, but the greatest care

should be taken to protect them from frost.

A useful "tip" in the filling of the boxes, if arrangement of the tubers rose-end upwards is required, is to tilt the box against a wall and build each row from the bottom, making the tubers fit tightly.

This prevents the potatoes rolling about, as they do if the filling is done on the flat, and saves both time and trouble. When filling large numbers of boxes it is not absolutely necessary to set the tubers on end; they may be thrown into them two layers deep. We, however, advise setting up the tubers on end whenever possible.—J. F. W.

SAVORY (*Satureia hortensis* and *S. montana*). — See *POTHERBS* and *SATUREIA*.

SAVOY CABBAGE.—See *CABBAGE, SAVOY*.

SAWDUST MANURE. — See *COW MANURE* and *HORSE MANURE*.

SAWFLIES.

There are a large number of small insects that go by the name of Sawflies. For instance, there is the well-known Gooseberry Sawfly, which, when it once gets a start, frequently strips the bushes of leaves in a very short time. We are not treating of them in detail under this heading because they are included in the article on *INSECT PESTS*. By reference to that article readers will obtain all the information they require to combat these pests successfully.

SAW-WORT.—See *SAUSSUREA* and *SERRATULA*.

SAXEGOTHEA.—For the best species see *TREES*.

SAXIFRAGA (ROCKFOIL. Nat. Ord. Saxifragaceæ).—Few plants are of so much importance in the rock garden as the Saxifrages, or Rockfoils. Many are also of high value for the flower border and wall garden. As edgings to the herbaceous border a considerable number are exceedingly useful, especially when growing over stones.

The number of species known to botanists is extremely great, and even those in cultivation are so numerous that it is impossible within the present limits to discuss them fully or to enumerate more than a representative selection. In addition, there are many varieties and hybrids, which are constantly being increased in number. All those mentioned are, with a few exceptions, hardy and easily cultivated, but their requirements vary according to the section to which the plants belong. General cultural details will be found under the respective headings of each section. The most highly appreciated are the encrusted or Silver Saxifrages (*Euaizoonias*); the Tufted Saxifrages (*Kabschias*); and the Mossy Saxifrages (*Dactyloides*). In the garden it is desirable to include representatives of other sections. There are Saxifrages suitable for sunny crevices or moraines; others which flourish in the shade, even when partially shaded by trees; and some, again, which love moisture and are most at home by the margin of a pond or stream.

Their appearance is as varied as their requirements, and a study of the genus will make it evident that the high importance claimed for these flowers is more than justified. It has, indeed, been said with truth that a garden without Saxifrages is "unthinkable." Such a garden lacks many of the most charming alpine flowers, and has about it a want of interest easily supplied by the inclusion of some of the fascinating plants comprised in this genus. The majority of those in cultivation are hardy and perennial, and will give satisfaction if grown according to the directions

under the headings of the respective sections. It is only proper to add that the nomenclature of the Saxifrages in nurseries is often extremely unreliable; and that those named here are perennial unless otherwise mentioned.

Saxifrage Sections. — The Saxifrages have been divided by botanists into numerous sections, and these afford valuable assistance in giving an idea of their general appearance and cultural requirements. The most recent grouping has been followed here, and the letters in brackets immediately after the name of each plant refer to the section in which it is included.

Bergenia Section. — Here we have a group of Rockfoils comprising a considerable number of good garden subjects, frequently found in nurseries as *Megaseas*. They have generally large, thick, fleshy leaves and panicles of flowers varying from purple to white. They look well by the sides of streams and in wild gardens, besides being valuable for the border and rockery, and any ordinary soil suits them. *S. ciliata* and *S. Stracheyi* should have a warm place. They are increased by division or seeds in spring or autumn, and are marked (Be) in the list.

Boraphylla Section. — The plants in this are of little importance for the garden and may be omitted, unless the owner has a desire for a botanical collection. They have small flowers in panicles and radical leaves. A moist and sunny position is the best. They are increased by division or seeds in spring, and are marked (Bo) in the list.

Cymbalaria Section.—This is a limited group, including one or two species of charming hardy annuals or biennials with small glossy leaves and bright flowers. They bloom for a long season. It is unnecessary to grow more than one species. They generally sow themselves in the garden, and delight in a cool, rather moist position on the rockery, retaining wall, or level ground. Seeds sown in the open in early spring will flower in autumn; if sown in early autumn the plants will flower the following spring. This section is marked (C) in the list.

Dactyloides Section. — The Mossy Saxifrages, as they are popularly called, constitute one of the most important groups of the genus. They vary considerably in size and character of foliage. Some make close mounds of moss-like verdure of high beauty. Others form masses of larger leaves, frequently finely cut, and of much charm when examined. The plants cover themselves with flowers, these being generally white or whitish, but there are also some with red or pink flowers, and new varieties of these shades are rapidly increasing in numbers. The Mossy Rockfoils love a cool position, such as the more northerly aspect of the rock garden, and make charming edgings. In hot or dry positions they are liable to become brown in the centres, and very large plants are peculiarly apt to become disfigured in this way. When this happens the plants should be pulled to pieces and replanted. They are of easy culture in any soil, and their propagation is almost absurdly simple. Small pieces set in the soil during the spring, summer, or early autumn months will generally root rapidly. Seedlings are easily raised by the ordinary methods for hardy perennials—either under glass or in the open. They are marked (Da) in the list.

Diptera Section.—This includes such well-known subjects as *S.*

sarmentosa, the old MOTHER OF THOUSANDS, so often grown in hanging pots and baskets in windows and greenhouses. Few of the plants are absolutely hardy in the whole of the United Kingdom, but *S. Fortunei* is a good Saxifrage for warm rockeries or moraines. The others are best under glass. These plants like a sunny place and rather light soil, not too wet in winter. Increase by offsets or runners, which are easily rooted, or by seeds in some cases. They are marked (Di) in the list.

ENGLERIA SECTION.—The Saxifrages belonging to the ENGLERIA section are of some importance, although not always satisfactory in the garden. They vary in character of foliage. Some grow in large rosettes resembling those of the EUAIZOONIA section; others have close, spiny foliage, like that of the KABSCHIAS. All are remarkable for the smallness of the flower proper and the large, conspicuous calyx, frequently the most ornamental part of the inflorescence. The ENGLERIA Rockfoils generally prefer sun, and look best in chinks of the rock garden. They prefer a light loam, with some lime added, and, though sun-lovers, ought not to be allowed to become too dry at any time. They are raised by seeds, sown in spring or when ripe, and hybridise freely with the Saxifrages of other sections. They are marked (E) in the list.

EUAIZOONIA SECTION.—This comprises the favourite Silver or Encrusted Rockfoils, among the most cherished of garden plants. They produce rosettes of varying size, generally marked along the edges of the leaves with a silvery encrustation, and with the remainder of the foliage of pleasing shades of silver, grey, or green. Some species present the appearance of little mounds of silvery-grey, composed of miniature rosettes, and throwing up short stems bearing panicles of charming flowers. Others, such as *S. Cotyledon* and its varieties, or the queenly *S. longifolia*, produce large braided rosettes of noble appearance and towering spires of flower of fine effect. As these Silver Saxifrages cross freely with each other, it is essential to propagate them by offsets, as seedlings rarely come true to the parent. In the case of *S. longifolia*, which does not produce offsets, it is necessary to save seeds from plants a distance from other species. Seeds can be sown when ripe, and germinate well on moss in the open or in pots or pans under glass. The offsets may be detached any time from early spring till autumn, and root well in sandy soil. Practically all the Rockfoils of this section delight in warm, sunny banks, and prefer a rather gritty soil and lime in some form. Many new hybrid Silver Saxifrages are being raised and put on the market. This section is marked (Eu) in the list.

HIRCULUS SECTION.—In this group we have a few plants of value for moist places in the rock garden, artificial bog, or by the sides of streams or ponds in sun. They have small, entire leaves and yellow flowers. *S. Hirculus major* is the best. They are propagated by division or seeds, and are marked (H) in the list.

ISOMERIA SECTION.—Only one species of this section is known in commerce. This is the plant often called *Boykinia aconitifolia*, which is correctly *Saxifraga aconitifolia*. It is of little account in the garden. The leaves are roundish, and the flowers are white. It is increased by division of the underground rhizomes or seeds. Well-drained soil is required for this, which is marked (I) in the list.

KABSCHIA SECTION.—An invaluable section, of which *S. burseriana* may be named as representative, and one of the most important of the genus. No rock garden can be considered complete without some representatives of these exquisite Rockfoils. They may be briefly described as constituting small mounds of spiny leaves of lovely shades of grey, green, or silver, and bedecked in their season by numerous flowers of the highest order of beauty. The blooms vary in colour, but some fine yellows are included, and few of these Tufted Rockfoils are valueless. Their nomenclature is difficult; and the frequent introduction of new species and varieties renders it impossible to do more than give a selection of the best plants of this section in commerce at the present time. These KABSCHIA Saxifrages usually prefer a light, sunny position, in a soil of loam, leaf-mould, and some sand and grit, with the addition of a modicum of lime. They flourish in the moraine, as well as in the rock garden. Propagation is effected by division or seeds. A little top-dressing with the compost indicated above is desirable in autumn and early spring, working it well among the leaves. They are marked (K) in the list.

MISCOPETALUM SECTION.—A limited section of useful and pretty Rockfoils with small, rather heart-shaped leaves and panicles of pleasing flowers. They are easy to grow, but have a liking for moisture and some shade. Almost any soil will suit, but, if heavy, a little leaf-mould, sand, and grit will be helpful. They are propagated by division or seeds, and are marked (M) in the list.

NEPHROPHYLLUM SECTION.—Only a few plants of this section are in cultivation. The best known, and one which fairly represents the general character of the group, is *Saxifraga granulata*, the MEADOW SAXIFRAGE, the double form of which, *S. granulata fl. pl.*, is often seen in gardens. These plants flourish in an open position and a moist soil, but can be cultivated in ordinary loam in the garden. They are propagated by division, by bulbils and seeds, and are marked (N) in the list.

PELTIPHYLLUM SECTION.—The only species of this in cultivation is *Saxifraga peltata*, a bold plant for the border, wild garden, or the sides of ponds or streams. It has handsome leaves of varying tints at the different seasons, and panicles of pink or white flowers. It delights in moisture, and is increased by division. It will be found marked (Pe) in the list.

PORPHYRION SECTION.—In this section of Rockfoils we have a few species only, but some of the varieties they yield are of extreme charm. They are, however, often shy of flowering in gardens, and, in consequence, are not so much grown. To induce them to flower they ought to have rather a cool position, yet one with a fair amount of sunshine, a poor soil, thoroughly well drained, and plentiful waterings in summer. The writer has found good results follow top-dressing with grit in early spring, working it well in with the fingers and then giving a good watering. These PORPHYRION SAXIFRAGES produce close carpets of small foliage, set with brilliant purplish or red flowers. Our native *S. oppositifolia* may be taken as representative of the group. Propagation is effected by division, and the plants are greatly benefited by pulling them to pieces and replanting every three or four years. They are marked (Po) in the list.

ROBERTSONIA SECTION.—A section comprising a few excellent garden plants. *Saxifraga umbrosa*, the LONDON PRIDE or NONE-SO-PRETTY,

is a good representative of the group, although some of the others are more refined in their effect. They do well in almost any soil, and are quite satisfactory under trees or in other shady places where few Rockfoils will thrive. They are increased by division or seeds, and are marked (R) in the list.

TRACHYPHYLLUM SECTION.—Only a small number of Rockfoils belong to this section, and, as a rule, these are not of much importance. The most useful are *S. aizoides*, the STREAMLET SAXIFRAGE, and its variety *aurantiaca*. They have entire leaves and yellow or whitish flowers. They delight in moisture, are propagated by division or seeds, and will be found marked (T) in the list.

We now give a

KEY TO THE SECTIONS, in order that readers, when studying the Selection of Sorts to follow, may be able to see at a glance to which section they belong:—Bergenia (Be); Boraphylla (Bo); Cymbalaria (C); Dactyloides (Da); Diptera (Di); Engleria (E); Euaizoonia (Eu); Hirculus (H); Isomeria (I); Kabschia (K); Miscopetalum (M); Nephrophyllum (N); Peltiphyllum (Pe); Porphyrion (Po); Robertsonia (R); Trachyphyllum (T). The list below is by no means an exhaustive one, as many hundreds of species and varieties are known. It includes, however, all the best and most useful sorts.

SELECTION OF SORTS.

Saxifraga aconitifolia (I).—White flowers in May. Height, 15 ins.

S. aizoides (T).—The STREAMLET SAXIFRAGE, with yellow flowers in June. Height, 4 ins. *S. a. aurantiaca* has orange flowers.

S. Aizoon (Eu).—White or spotted red flowers in May. Height, 8–10 ins. Numerous varieties are available, all similar to the above. A few of the best are:—*altissima*, *balcana*, *baldensis*, *californica*, *carinthiaca*, *cultrata*, *dubia*, *elongata*, *flavescens* (yellowish), *incrustata*, *intacta*, *la graveana*, *lutea* (yellow), *Malyi*, *minima*, *minor*, *notata*, *paradoxa*, *pectinata*, *punctatissima*, *rosea* (red), *sempervivoides*, *stabiana*, *thyrsiflora*, and *triternata* (pink).

S. ajugifolia (Da).—White flowers in May. Height, 9 ins.

S. apiculata (K).—Pale yellow flowers in March. Height, 2 ins.

S. Apple Blossom (Da).—Pink flowers in May. Height, 6 ins.

S. aretioides (K).—Yellow flowers in May. Height, 3 ins.

S. Arkwrightii (Da).—Red flowers in May. Height, 6 ins.

S. aspera (T).—Yellowish-white flowers in May. Height, 3 ins.

S. Bakeri (Da).—Red flowers in May. Height, 3 ins.

S. Bertoloni (E).—Rose and yellow flowers in May. Height, 6 ins.

S. biflora (Po).—Red flowers in May. Height, 2 ins.

S. Borisii (K).—Yellow flowers in May. Height, 3 ins.

S. Boydii (K).—Yellow flowers in March. Height, 3 ins. *S. B. alba* is white.

S. burseriana (K).—White flowers in March. Height, 3 ins. The varieties *crenata*, *Gloria*, *grandiflora*, *magna*, and *major* are all white.

S. bursiculata (K).—White flowers in March. Height, 3 ins.

S. caesia (K).—White flowers in May. Height, 3 ins.

S. caespitosa (Da).—White flowers in May. Height, 6 ins.

S. Camposii (Da).—White flowers in May. Height, 6 ins.

S. carniolica (Eu).—Creamy-white flowers in May. Height, 15 ins.

S. cartilaginea (Eu).—White flowers in May. Height, 9 ins.

S. catalaunica (Eu).—White flowers in May. Height, 15 ins.

S. Cherry Trees (K). — Yellow flowers in April. Height, 3 ins.

S. ciliata (Be).—Pink flowers in April. Height, 1 ft.

S. Clibrani (Da).—Red flowers in May. Height, 6 ins.

S. Clusii (Bo).—White and pink flowers from April to May. Height, 6 ins.

S. cochlearis (Eu).—White flowers in June. Height, 1 ft. *S. c. minor* only grows 3 ins. high.

S. cordifolia (Be).—Flowers pink, etc., in May. Height, 1 ft. There are many varieties of this.

S. Cotyledon (Eu).—White flowers in June. Height, 2 ft. Numerous varieties of this are available, including *islandica, nepalensis, pyrenaica,* etc., all of which are similar to the above.

S. crassifolia (Be).—Pink flowers in May. Height, 1 ft.

S. Craven Gem (Da).—Red flowers in May. Height, 6 ins.

S. crustata (Eu).—White flowers in June. Height, 6 ins.

S. cuneifolia (R).—White flowers in May. Height, 6 ins.

S. cuscutaeformis (Di). — White flowers in June. Trailer.

S. decipiens (Da).—White to red flowers in May. Height, 6 ins.

S. diapensioides (K). — White flowers in April. Height, 2 ins. *S. d. tombeanensis* has white flowers.

S. Dr Ramsay (Eu). — White flowers in June. Height, 1 ft.

S. exarata (Da).—White flowers in May. Height, 9 ins.

S. Faldonside (K).—Yellow flowers from April to May. Height, 3 ins.

S. Fergusoni (Da).—Red flowers in May. Height, 4 ins.

S. flagellaris (T).—Yellow flowers in May. Height, 3 ins.

S. Forsteri (K).—Yellow flowers in May. Height, 3 ins.

S. Fortunei (Di).—White flowers from August to September. Height, 9 ins.

S. geranioides (Da). — White flowers in June. Height, 9 ins.

S. Geum (R).—White and spotted red flowers in May. Height, 9 ins.

S. granulata (N).—The MEADOW SAXIFRAGE, with white flowers in April. Height, 6–10 ins. *S. g. flore pleno* has double white flowers.

S. Grisebachii (E). — Crimson flowers in April. Height, 6 ins.

S. Guildford Seedling (Da).—Red flowers in May. Height, 4 ins.

S. Hirculus (H).—Yellow flowers in August. Height, 4–8 ins. *S. H. major* grows 10 ins. high.

S. Hostii (Eu).—White flowers in June. Height, 15 ins. *S. H. altissima* grows 18 ins. high.

S. hypnoides (Da).—The DOVEDALE MOSS, with white and other coloured flowers in May. Height, 6 ins.

S. Irvingii (K).—Rose flowers in May. Height, 3 ins.

S. kestoniensis (K).—White flowers in April. Height, 3 ins.

S. kolenatiana (Eu).—Pink flowers in June. Height, 18 ins. *S. k. major* grows 2 ft. high.

S. Kotschyi (K).—Yellow flowers in May. Height, 3 ins.

S. Kyrilli (K).—Yellow flowers in May. Height, 3 ins.

S. L. C. Godseff (K).—Yellow flowers in April. Height, 3 ins.

S. ligulata (Be).—Purple flowers in May. Height, 1 ft. There are several varieties of this, including *alba,* which is white.

S. lilacina (K).—Lilac flowers in April. Height, 2 ins.

S. lingulata (Eu).—White flowers in June. Height, 15 ins. There are numerous varieties of this, including *australis, Bellardii, lantoscana,* etc., which are similar to the above.

S. longifolia (Eu).—White flowers in June. Height, 2 ft.

S. macnabiana (Eu).—White and spotted red flowers in June. Height, 15 ins.

S. marginata (Syn. *S. Boryi*) (K).—White flowers in April. Height, 3 ins.

S. media (E).—Purple flowers in May. Height, 6 ins.

S. Miss Stormonth (Da).—Red flowers in June. Height, 3 ins.

S. muscoides (Da).—White flowers in May. Height, 3 ins. *S. m. atropurpurea* has red flowers.

S. mutata (Eu).—Orange flowers in June. Requires a damp soil. Height, 15 ins.

S. oppositifolia (Po).—Purple flowers from March to April. Height, 1½ ins. *S. o. alba* has white flowers, while *S. o. pyrenaica* and *S. o. superba* have red-purple flowers.

S. paradoxa (Eu).—Yellowish-white flowers in June. Height, 9 ins.

S. Paulinae (K).—Yellow flowers in April. Height, 2 ins.

S. pedatifida (Da).—White flowers in May. Height, 9 ins.

S. peltata (Pe).—The UMBRELLA PLANT, with white or red flowers from April to May. Height, 3–5 ft.

S. Petraschii (K).—White flowers in April. Height, 3 ins.

S. porophylla (E).—Rose and yellow flowers in May. Height, 6 ins.

S. primuloides (R).—Rose to pink flowers in June. Height, 6 ins.

S. Red Admiral (Da).—Red flowers in May. Height, 6 ins.

S. retusa (Po).—Rosy to crimson flowers from June to July. Height, 4 ins.

S. rivularis (N).—White flowers in May. Height, 4 ins.

S. rocheliana (K).—White flowers in March. Height, 3 ins. *S. r. coriophylla* is similar to the above.

S. sancta (K).—Yellow flowers in April. Height, 3 ins.

S. sarmentosa (Di).—Flowers white, yellow etc., from June onwards. Height, 9 ins. *S. s. tricolor* has variegated leaves.

S. scardica (K).—White flowers in May. Height, 3 ins.

S. Sibthorpii (C).—Yellow flowers from May to September. Height, 3 ins.

S. Stracheyi (Be).—Pink flowers in April. Height, 1 ft.

S. Stribrnyi (E).—Purple flowers in May. Height, 6 ins.

S. taygetea (M).—White and spotted scarlet flowers in May. Height, 9 ins.

S. thessalica (E).—Red and yellow flowers in May. Height, 6 ins.

S. trifurcata (Da).—The STAG'S-HORN ROCKFOIL, with white flowers in May. Height, 9 ins.

S. umbrosa (R).—The well-known LONDON PRIDE, with white and pink flowers in June. Height, 9 ins. *S. u. Andrewsii*, and *S. u. serratifolia* are similar to the above.

S. valdensis (K).—White flowers in June. Height, 2 ins.

S. Vandellii (K).—White flowers in June. Height, 2 ins.

S. Wallacei (Da).—White flowers in May. Height, 9 ins.

S. Zimmeteri (Eu).—White flowers in June. Height, 10 ins.—S. A.

NEW VARIETIES.

Saxifraga burseriana sulphurea.—Sulphur-yellow flowers.

S. J. C. Lloyd Edwards.—Rosy-crimson flowers on plants of very dwarf, compact habit.

S. Kewensis rosea.—Pale rose-white flowers and purplish-red stems.

S. Mrs R. J. Wickham.—Large pale rose flowers, veined crimson, on plants 6–9 ins. high.

S. oppositifolia R. M. Pritchard.—Large rosy-purple flowers.

S. Sundermanni.—White flowers on short stems, in dense rosettes.—W. J. C.

SAXIFRAGA RUST.—See *DISEASES OF ROCK PLANTS.*

SAXIFRAGE SECTIONS.—See *SAXIFRAGA*.

SAXIFRAGES FOR WALL GARDENS. See *WALL GARDENING*.

SCABIOSA.—See *SCABIOUS*.

SCABIOUS (*Scabiosa*. Nat. Ord. Dipsaceæ).—For cutting or for border decoration the annual Scabious are particularly useful, as the rounded, pin-cushion-like heads of bloom last a long time, and are carried on long, wiry stems. The best results follow half-hardy treatment, but autumn flowering can be obtained by sowing out of doors in April. Planted in groups, each plant 15 ins. from its neighbour, a fine effect is produced if the better strains are grown and lightly supported with slender sticks. Of the several annual species only one is of real garden value, namely :—

Scabiosa atropurpurea.—An old garden plant, and formerly known as *Asterocephalus*, and *Pterocephalus atropurpureus*. Seeds of distinct colour forms are obtainable, and the range is from white, through pink, salmon, rose, lilac, blue, purple, and yellow to scarlet, crimson, and blackish-maroon. It flowers freely through the summer, and grows 2–3 ft. high. A fuller description of it will be found in our article *SWEET SCABIOUS*, which see.

Perennial Border Species.—A very large number of these have been described, and long lists are frequently inserted in other gardening dictionaries. The following selection, however, contains, in our opinion, the cream of the sorts, many of which are valuable for cutting, and all of which may be grown with little difficulty in ordinary rich garden soil in a sunny or very lightly shaded position. They are easily increased by seeds sown in the usual way for perennials, or by division of the roots in November or March, which last is the best time to plant.

Scabiosa australis.—This is a purple midsummer flowering sort growing 1½ ft. high.

S. caucasica (Syns. *S. connata* and *S. elegans*).—This is probably the most popular of all the Scabious. Its flowers, of the extremest pale blue, are produced with remarkable freedom from June to August on plants 1–2½ ft. high. The many so-called varieties of this offered by the nursery trade are not recognised at Kew.

S. connata.—Syn. *S. caucasica* above.

S. elegans.—Syn. *S. caucasica* above.

S. graminifolia.—This, described under the Rock Garden Species, is useful too, near the front of borders.

S. japonica (of the trade).—This is no longer a recognised variety.

S. lucida.—This is a pretty blue species flowering freely during the summer months, and growing about 2 ft. high.

S. ochroleuca.—This is a useful yellow midsummer and late summer flowering sort about 1½ ft. high.

S. speciosa.—This is an attractive blue summer flowering Scabious of the average height.

S. Succisa (DEVIL'S-BIT SCABIOUS).—This sort bears blue flowers in June and July, and averages 1½ ft. high.

S. sylvatica.—This useful sort bears white flowers about midsummer on plants 1½ ft. high.

Rock Garden Species.—The two species described below make excellent rock garden plants. They will both thrive in sunny positions in well-drained, loamy soil, and are propagated by division of the roots in autumn and spring.

Scabiosa graminifolia.—This forms a woody rootstock, with tufts of

narrow, silvery leaves. Flowers pale mauve. Flowering Period, June to September. Height, 1 ft.

S. Pterocephala (Syn. *Pterocephalus Parnassi*).—This forms mound-like tufts of grey-green foliage. Flowers pale purple. Flowering Period, June to September. Height, 6 ins.

SCALDING SOIL.—See *SOIL STERILISATION.*

SCANDIX (SHEPHERD'S NEEDLE. Nat. Ord. Umbelliferæ).—This is an uninteresting genus of weedy plants sometimes offered to unwary amateurs. *S. Pecten-Veneris* is the best known species. It is the COMMON SHEPHERD'S NEEDLE, a troublesome weed in some districts.

SCAPTOMYZA.—See TURNIP LEAF MINER in *INSECT PESTS.*

SCARBOROUGH LILY (*Vallota purpurea.* Nat. Ord. Amaryllidaceæ).—This is a well-known and popular plant, not only on account of the bright scarlet blooms which it throws up in August and September, and which are most effective either when growing for conservatory decoration, or when cut for vases; but also because it is an uncommonly good window-plant. Some excellent examples are annually to be seen in cottages and small houses where there is no glass accommodation whatever. It is only half-hardy.

Culture.—The bulbs are not very particular as to soil. For preference this should be fairly stiff loam with a little sand and leaf-mould, and when potting the bulbs should not quite be covered with soil, though firm potting is essential. As repotting is only advisable once in four years, the plants must be fed when they are in active growth. This can be seen by the pushing up of new leaves. The Scarborough Lily has naturally evergreen foliage, so the plants must not be "dried off," and care must be taken to retain healthy foliage all the year round. A winter temperature of 40–50° F. should be maintained, and during this period very little water will be required. As small offsets are made, they may be carefully removed and grown on in other pots till large enough to flower.

Varieties.—All the forms offered are very similar to the typical old, scarlet *Vallota purpurea.* They are probably seminal varieties.

Vallota purpurea eximia has a white throat. It is even more beautiful than the old form, especially if the segments are wide and open.

V. p. major has larger flowers than the type.

V. p. minor is a small-flowered sort.

All the varieties of Scarborough Lily flower in late August or September. Their leaves in well-grown examples average 12–15 ins. in length, and the flower stems 18–24 ins. in height.—J. J. & E. T. E.

SCARLET BARK WILLOW (*Salix alba caerulea*).—See *TREES.*

SCARLET CLEMATIS (*Clematis coccinea*).—See *CLIMBING AND TRAILING PLANTS.*

SCARLET FLY-CAP.—See HARMFUL FUNGI in *FUNGI: EDIBLE AND HARMFUL.*

SCARLET GOURD.—See *ORNAMENTAL GOURDS.*

SCARLET HAW (*Crataegus coccinea*). See *TREES.*

SCARLET HOLLY (*Desfontainea spinosa*).—See *CLIMBING AND TRAILING PLANTS.*

SCARLET OAK (*Quercus coccinea*).—See *TREES.*

SCARLET PIMPERNEL.—See *WEEDS.*

SCARLET POPPY (*Papaver Rhoeas*). See *POPPIES.*

SCARLET RUNNER, or RUNNER BEANS.—See *Beans* and *Phaseolus*. See also *Ornamental Vegetables*.

SCARLET TURK'S CAP LILY (*Lilium chalcedonicum*).—See *Lilies*.

SCENERY IN GARDENING. — See *Landscape Gardening*.

SCHELLOLEPIS.—Now included in the genus Polypodium, for which see *Ferns and Fern Gardening*.

SCHIVERECKIA.—Now included in the genus *Alyssum*.

SCHIZANTHES.—Now included in the genus *Narcissus*.

SCHIZANTHUS (Butterfly Flower. Nat. Ord. Solanaceæ).—This is a genus of very decorative half-hardy annuals, thriving in rich, free soil, and propagated by seed. The height averages 1½–4 ft.

Culture.—Seed is best sown in August or September for spring display, and in March for summer and autumn flowering. Autumn sown plants should be kept cool and rather dry during winter, a temperature of 45° F. being sufficient. By the judicious pinching of the leader first, and subsequently of the lateral growths, bushy and sturdy plants will be formed, which, later, will be a mass of bloom from top to bottom. Spring sown seedlings are treated in the ordinary way for half-hardy annuals.

Uses.—For conservatory decoration no plant surpasses this for wealth of bloom. The species *S. pinnatus* and *S. retusus* are suitable for bedding out of doors, but only a rich, free soil should be used.

Varieties. — The best sort is *S. Wisetonensis*, a particularly fine strain known as *Dr Badger's Hybrids* being procurable from seed specialists. Other useful species are as mentioned above, *S. pinnatus* and *S. retusus*.—J. L. G.

New Variety.

Schizanthus Wisetonensis Snowflake.—This is pure white except for the anthers. It is of dwarf habit, and very floriferous.

SCHIZOCODON (Japanese Moonwort. Nat.Ord.Diapensiaceæ).—There is only one species in this genus, which is closely allied to the genus *Shortia*. This, *Schizocodon soldanelloides*, is a shade-loving plant, and requires well-drained, sandy loam and peat in a sheltered situation, preferably in the rock garden. It is not easy to increase, but may be propagated by careful division in spring. It bears tufts of evergreen leaves, tinted crimson in autumn, and bright rose-fringed flowers from April to June. Its height is 4 ins.

New Variety.

Schizocodon ilicifolia.—This is a white-fringed, dwarf-growing evergreen subject, suitable for a shady part of the rock garden.

SCHIZONEURA.—See Woolly Aphis in *Insect Pests*.

SCHIZOPETALON (Nat. Ord. Cruciferæ).—Lovers of fragrant hardy annuals should include the Chilian species of this little known genus (*Schizopetalon Walkeri*) in their gardens. It has white flowers that give forth a very sweet odour in early morning, during evening, or after a light rain. It succeeds in any good garden soil, and sowings should be made at intervals from early spring onward to secure a continuance of flowers and fragrance. It may also be raised from seed as a half-hardy annual and planted out in the borders after being duly hardened off. The height when in bloom rarely exceeds 1 ft.

SCHIZOPHRAGMA.—For the best species see *Climbing and Trailing Plants*.

SCHIZOSTYLIS.—See *KAFFIR LILY.*

SCHOENUS.—See *BOG RUSH.*

SCHOMBURGKIA.—See *ORCHIDS.*

SCHOOL GARDENING.

The question of school gardening is no longer such a vexed one as it used to be. Most parents realise the great advantages resulting from their young people learning gardening while they are young, though there are still, alas, a fair number of parents who do not like their children (especially their daughters), to soil their hands by direct contact with Mother Earth.

Though many primary and secondary schools have their gardens, there are hundreds of small semi-private schools where gardening has not yet been started. The bigger public schools for both boys and girls have during the years of War often opened their eyes for the first time to the profitable nature of gardening, but many girls' private boarding schools have done nothing whatever, and will continue to do nothing whatever, in this direction unless some one can persuade them to the contrary.

Even with no grant from the Board of Education, school gardening can be made profitable. Girls of 12–18 can dig very creditably provided they are taught how, and do not overtax themselves by attempting to do too large an area at a time. A quarter of an acre properly cultivated will provide enough food in the way of green and second vegetables to keep the 30–40 scholars during the whole of term time, and if very heavy cropping potatoes are grown and treated well as regards manure they should be able to keep themselves in this crop also with but little extra ground.

As with everything else, the utmost care must be taken that all the children who work at School Gardening start right from the very first. If they begin by holding their tools wrong, by planting loosely, or by doing any of the hundred and one things they may do in an incorrect manner, it will be very difficult to break them of the habit. Constant supervision is essential to success, and the teachers must be able to *show* the pupils exactly how things should be done.

In the article on *SCHOOL GARDENS* which follows, our contributor deals with some of the many practical points connected with this all-important subject.—EDITOR.

SCHOOL GARDENS.

The first question for the Head Teacher of a school to consider when arranging for a School Garden is the *number of children* who would be allowed by the Board of Education to receive instruction. Information on this point is found in articles 3 to 41, Schedule III. (A), of the Board's Code. An important point to remember is, that there must be "one Teacher to every 14 scholars present at one time," but generally all courses are two-year courses of instruction with separate plots, worked by a first and second year scholar together, and such classes may consist of "20 under one Teacher," provided *the consent of the Board has been obtained beforehand.* As the gardening year commences in November each year, this consent should be obtained in October, for failure to comply with this regulation may result in the loss of the grant.

Age of Children.—The children who may be registered for attendance in School Gardening must be eleven years of age at the date of the first lesson they attend, though in special circumstances boys of ten or over may be included. The Board will not sanction the in-

clusion on the register of boys under ten, or girls under eleven years of age.

Attendance at instruction in gardening, which is usually two hours per week, may not be marked in the Gardening Register excepting where the scholars do practical work

Arrangement of Garden.—This is the second point to consider. For twenty scholars a piece of ground is required in size about a quarter of an acre. This should be divided into fifteen plots about 2½ perches each. The ideal arrangement is shown in the diagram (Fig. 1).

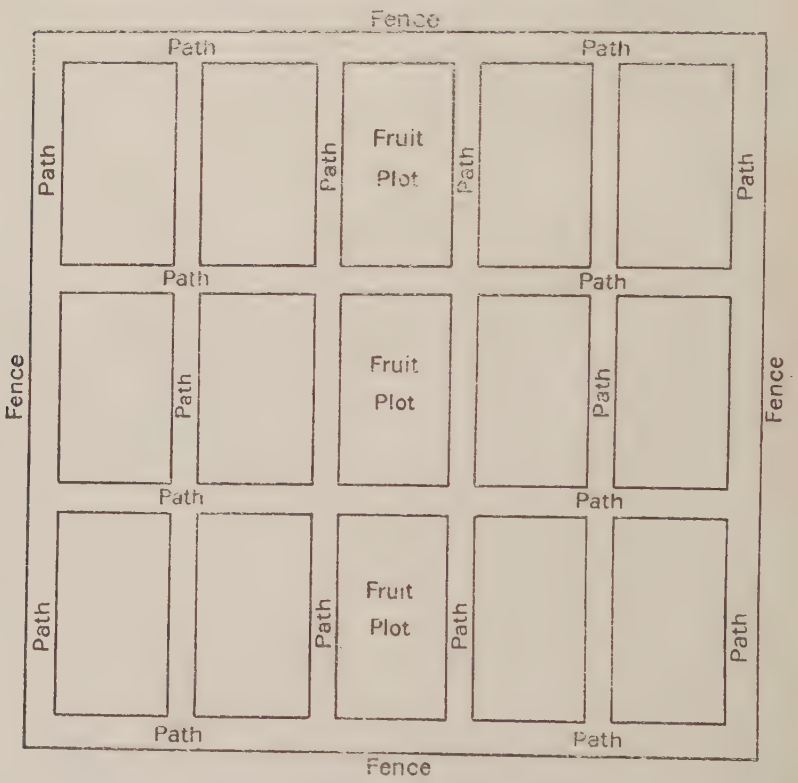

FIG. 1.—Plan of School Garden.

" outside " on the plots, or " inside " with budding, grafting, seed testing, and such like. The Board of Education have ruled that theoretical lessons on gardening may not be counted. For registration purposes the whole twenty of the scholars should be marked on *one* register, and grant claimed on the best fourteen.

The plots should be rectangular, about 12 yds. by 6 yds., the paths being about 2 ft. wide.

The centre plots would be permanently used for fruit trees, where all the scholars could receive instruction and practise grafting, budding, etc.

One plot would be used as a seed plot to raise the various plants

required for the other plots, and one plot for a model plot for demonstration purposes. The seed plot and the model plot should be changed each year.

If possible arrange the plots in a rectangle, so that the rows of the crops run north and south. The advantage of arranging each plot with the length twice its breadth is to enable the scholars to grow one row of each kind of vegetables.

The whole garden should be fenced in with strong posts and strong wire running *through* the posts, and not nailed to them. Where, in many country districts, rabbits damage the crops, there should be further protection by wire netting 1 yd. high all round the fence, and sunk not less than 12 ins. deep. The plots if arranged in the above manner require only three "lines" when planting, as one line will stretch right across three plots. When one is standing outside the whole plot he can see all of the same kind of vegetables at one glance. A perfect rotation of crops is ensured, and the teacher is enabled to supervise easily the work being done.

What to Grow.—This is our third point. All kinds of vegetables should be grown on each plot, and it is advisable for teacher and scholars to prepare a diagram showing what is grown one year, and another diagram showing the next year's crop. This ensures that the same kind of crop will not be grown two years in succession on the same ground.

Vegetables such as Broccoli, Cauliflowers, Leeks, and Winter Greens will take the places of those crops that mature early.

Herbs such as sage, thyme, mint, etc., can be easily grown round the fruit plots, and marrows may be grown either round the fencing or allowed to run on the fruit plots.

The diagram (Fig. 2) shows crops on plots during the first and second seasons.

First Year.	Second Year.
Shallots.	Runner Beans.
Lettuce.	Shallots.
Early Potatoes.	Lettuce.
Late Potatoes.	Early Potatoes.
Dwarf Beans.	Late Potatoes.
Carrots.	Dwarf Beans.
Peas.	Carrots.
Parsnips.	Peas.
Broad Beans.	Parsnips.
Onions.	Broad Beans.
Cabbage.	Onions.
Beet.	Cabbage.
Turnips.	Beet.
Runner Beans.	Turnips.

Fig. 2.—Crops for School Garden.

The third year and successive years will follow on the same plan.

Amount of Seed Required.—For such a school garden as outlined above, the following quantities will be found sufficient per season: Beans (Broad), 1 qt.; Beans (Dwarf), 1 pt.; Beans (Runner), 1 pt.; Beet, 2½ oz.; Broccoli, ½ oz.; Brussels Sprouts, ½ oz.; Cabbage, ½ oz.; Carrot, 1½ oz.; Cauliflower, ½ oz.; Celery, ½ oz.; Cucumber, one packet of 20 seeds; Leek, ½ oz.; Marrow, two packets of 20 seeds each; Onions (Autumn), ½ oz.; Onions (Spring), 2 oz.; Parsnip, 1½ oz.; Peas, three pints; Potatoes (early), 2 pecks; Potatoes (late), 2 pecks; Tomato, one packet of 100 seeds; Turnip, 1½ oz.

Enough Runner and Dwarf Beans

and Potato Seed should be saved so that new stock is required only once in two years.

Manure Required. — Four loads of farmyard manure, together with 3 lb. of Sulphate of Ammonia, or 3 lb. Nitrate of Soda (according to whether the soil is heavy or light), and 14 lb. of Basic Slag or Superphosphate, will be needed per season. Potash manures being difficult to obtain, ashes from burnt hedge clippings and wood should be used instead. The use of these manures is described elsewhere in this work.

The Tool Shed. — This is a necessity for every School Garden. There must be pegs (wooden) all round the inside of the shed. These pegs and the tools must be small and numbered, so that each scholar always uses the same tools, and thus order and cleanliness are ensured.

Each scholar should be provided with a set of tools consisting of a spade, fork, Dutch hoe, swan-necked hoe, and a rake. In addition there should be for general use three "lines," ½ doz. small handforks, ½ doz. garden trowels, ½ doz. dibbers made in the Manual Training Centre attached to the school, also a rain gauge, and a ground thermometer.

Note Taking.—Each scholar must be provided with a *notebook* and a *diary*. In the former he records his work on the plot, his observations such as the length of time the seed took to germinate, the presence of fly, grub, etc., the poor or excellent state of his crops, his methods adopted, the date of lifting the crop, the use of artificial manures, etc. In the diary, which is written during composition lessons, he will carefully put down the main points from his notebook, what he did, how, and why he did it. His notes will show the effect of the weather (rain, drought, frost, etc.) on his crops. It will be found that each scholar can fill two pages of an ordinary exercise-book in his diary each week. The latter pages of the diary should be ruled, a page for each month showing at 9 a.m. each day degrees registered by ground thermometer, thermometer showing temperature in air; direction and force of wind, also amount of rainfall, and weather forecast. The last page of the diary should be ruled to show a balance sheet, to include cost of seeds, etc., value of produce grown, so that it can easily be seen whether the year's working has been a profitable one or not.

Disposal of Produce.—A word must be said on this important matter. The greater part of the produce is usually sent to the cookery centres attached to the schools, who are thus able to supply dinners very cheaply; even during the War, dinners could be supplied for five days in each week at a cost of a shilling each child per week, because of the free garden produce received from the school gardens.

The remainder of the produce may well be given to the children from their own plot, who take it home and proudly exhibit to their parents what they have grown. The fruit trees (apple, pear, plum, etc.), which the children have grafted, are sold to them very cheaply. The effect in the children who work on the gardens is a very wholesome one; it encourages good work, produces the right kind of emulation amongst them, and trains them to see and act for themselves. All the other lessons in school are helped considerably by school gardening, and instead of looking upon it as an extra subject which may be lightly put aside, it relieves

considerably the drudgery of many other lessons.—W. By.

SCIADOPITYS.—For the best species see *TREES*.

SCILLA (SQUILL, or WOOD HYACINTH. Nat. Ord. Liliaceæ).—The Scillas are for the most part hardy bulbous plants, which flower in the spring or early summer. The best known plants are the Blue Squills and the Wood Hyacinths.

Culture.—Any good garden soil suits the majority of the species. The Wood Hyacinths, of which there are two forms—the English and the Spanish—are excellent for naturalising in thin woodlands. They should be planted in October. It is well to clear away the roots and weeds from the patches where they are to be put, and to add some rich, light soil to give the bulbs a start when rooting. Treated in the same way as tulips, they may be grown in pots, placing each bulb ½ in. below the top of the soil; they do not then need "plunging." The Blue Squills should be planted in September and October in any good garden soil. They make good edgings to beds. The Peruvian Squill is only half-hardy except in favoured places in the British Isles. On account of the size of the flower heads, each bulb should be put into a 4-inch pot by itself. The winter temperature must not be above 50° F., as they resent much heat.

Species and Varieties. — The best species are briefly described below :—

Scilla amoena[1] (STARHYACINTH).—This bears blue flowers in March, on plants 3 ins. high.

S. amoenula.—Syn. *S. sibirica*, which see.

S. bifolia.—This bears pretty blue flowers in early March. There are other colours of this variety, but they are very scarce. Height, 6 ins.

S. campanulata.—Syn. *S. hispanica*, which see.

S. elongata.—Syn. *S. peruviana*, which see.

S. festalis (Syns. *S. nonscripta* and *S. nutans*).—This is the ENGLISH WOOD HYACINTH or BLUEBELL blooming in April, of which we are all so fond. Pink and white varieties can be had as well as the normal blue. Height, 1–1½ ft.

S. hispanica (Syn. *S. campanulata*).—This, the SPANISH SQUILL, is larger than *S. festalis*. Its bells are set all round the spike, which stands upright. The flowers are blue, white, and pink, and are produced in April. Good colour forms are *alba* (white); *Blue Queen* (large pale blue); *Rosalind* (rose-pink); and *Rose Queen* (pale lilac-rose). All average 18 ins. in height.

S. italica.—This bears charming blue flowers in May, and grows about 9 ins. high.

S. Lilio-hyacinthus.—This is a pretty blue species flowering in May and June. It grows about 12 ins. high.

S. nonscripta and *S. nutans.*—Syn. *S. festalis*, which see.

S. peruviana (Syn. *S. elongata*).—Notwithstanding its English name, PERUVIAN SQUILL, this species comes from Algeria. Its flowers, which are produced in May, are pale blue and densely set on a dwarf spike about 8–10 ins. high, forming a flattened cone. The plant is only half-hardy.

S. sibirica (Syn. *S. amoenula*).—This is the well-known BLUE SQUILL, producing dark blue flowers in March. The sub-variety *alba* is

[1] We describe here the plant named by Linnæus. One of exactly similar name is synonymous with *S. messeniaca*, a plant of insufficient beauty to include.—EDITOR.

decidedly good, the colour being pure white. Height, 4–6 ins.

S. verna (Syn. *S. umbellata*).—This, the SEA ONION, is available in rose-pink, pure white, and sky-blue. It flowers from April to May, and grows about 3 ins. high.—J. J. & E. T. E.

SCIRPUS (CLUB RUSH. Nat. Ord. Cyperaceæ).—This is a genus of hardy marsh or aquatic plants of the easiest culture, but of small value. The best known species is *S. lacustris*, the common BULRUSH, of which there are several forms, mostly troublesome weeds in ponds, rivers, and lakes. *S. sylvaticus* is not so coarse, growing only about 1 yd. in height. Unless the water garden is very extensive this genus may be dispensed with.

SCISSORS.—See *GARDEN TOOLS*.

SCLAREA.—Now included in the genus *SALVIA*.

SCLEROTINIA DISEASES. — See *DISEASES OF PLANTS*.

SCOLOPENDRIUM.—For the best species and varieties see *FERNS AND FERN GARDENING*.

SCOLYMUS (GOLDEN THISTLE. Nat. Ord. Compositæ).—This is a small genus containing two hardy herbaceous perennials and one hardy annual species—the last named need not be described here. *S. grandiflorus* bears large yellow flowers in May, and grows about 1 yd. high. Referring to the other hardy perennial species (*S. hispanicus*), which bears yellow flowers in August and also grows 1 yd. high, Paxton says that its roots are usually as good as Scorzonera (see article on *SCORZONERA*), and that the leaves and stalks are eaten as Cardoons by the people of Salamanca (see article on *CARDOONS*). The same authority refers to the fact that the flowers are used for adulterating Saffron (see article on *MEDICINAL HERBS*). The two species described above will thrive in ordinary garden loam in a sunny position, and may be propagated in the spring by division of the roots, at which time they may be successfully planted, or by seeds sown outside in the early summer.

SCOLYTUS. — See FRUIT BARK BEETLES in *INSECT PESTS*.

SCORODONIA.—Now included in the genus *TEUCRIUM*.

SCORODOSMA.—Now included in the genus *FERULA*.

SCORPION SENNA.—The genus CORONILLA. See *SHRUBS*.

SCORZONERA (*Scorzonera hispanica*. Nat. Ord. Compositæ).—This is perhaps the most neglected vegetable finding a place in seed lists to-day, a fact much to be deplored, seeing its season of usefulness is during the dull winter months when fresh vegetables are none too plentiful and during very severe weather practically unobtainable. In such times as these, the grower, who the previous summer gave proper attention to his rows of this, has something to be thankful for. True, the taste for this is an acquired one, and very few are favourably impressed with the first dish presented to them, but in reality our inherent conservatism and prejudice against anything new in the way of vegetables account very largely for the unpopularity of this crop among growers and consumers alike. Perhaps now the true value of home-grown vegetables is more fully appreciated, Scorzonera will share with other little-known vegetables wider recognition of its undoubted value.

Culture.—The soil for this crop needs to be very deeply worked, it being sheer waste of seed to sow in shallow soil, or ground simply dug over in the usual way. No manure

of any kind need be added; in fact, fresh stable manure if dug into the soil invariably results in worthless roots. The aim is to secure one single root from each plant, and this as straight as possible.

Seed may be sown in April. Sow only in shallow drills, not less than 15 ins. apart. When well through the soil, thin out the seedlings to 9 ins. or 1 ft. apart. Keep the bed free from weeds, but do not attempt artificial watering.

In November the roots may be dug up and stored between layers of dry earth, or, better still, allowed to remain in the bed to be dug as required. Strictly, this crop is biennial, and extra large roots result if two years are allowed for growth.

Variety.—The *Giant Russian* is the best sort to grow.—F. R. C.

See also *VIPER'S GRASS*.

SCOTCH ASPHODEL (*Tofieldia palustris*).—See *FALSE ASPHODEL*.

SCOTCH ELM (*Ulmus montana*).—See *TREES*.

SCOTCH HEATH (*Erica cinerea*).—See *HEATHS*.

SCOTCH KALE.—See DWARF SCOTCH KALE in *BORECOLE, or KALE*.

SCOTCH LABURNUM (*Laburnum alpinum*).—See *TREES*.

SCOTCH LOVAGE (*Ligusticum scoticum*).—See *LIGUSTICUM*.

SCOTCH MAPLE (*Acer dasycarpum*).—See *TREES*.

SCOTCH PINE (*Pinus sylvestris*).—See *TREES*.

SCOTCH ROSE (*Rosa spinosissima*).—See *ROSE SPECIES*.

SCOTCH THISTLE (*Onopordon Acanthium*).—See *ONOPORDON*.

SCOTCH or WYCH ELM (*Ulmus montana*).—See *TREES*.

SCROPHULARIA.—See *FIGWORT*.

SCRUB OAK (*Quercus Catesbaei* and *Q. undulata*).—See *TREES*.

SCUTELLARIA (SKULL CAP. Nat. Ord. Labiatæ).—This is a large genus of hardy herbaceous perennials, half-hardy greenhouse, or stove plants. It is only the former class we need trouble with here, of which the species require ordinary culture such as is bestowed upon other hardy perennials. Some are weedy plants of no garden value, but enemies to increased food production. All are easily propagated by sowing seeds in the usual way in the summer, or by root division in the autumn or spring, at which times they may be successfully planted.

Perennial Species.—We briefly describe below some of the more important:—

Scutellaria alpina.—This and its variety *versicolor* may be used for the rougher portions of the rock garden. Both bear purple flowers in August, and grow 6 ins. high.

S. altissima.—This is a sort bearing very deep purple flowers from July to August, and growing about 12 ins. high.

S. galericulata. — This is the COMMON SKULL-CAP, a useful weed fully described under SKULLCAP in our article on *MEDICINAL HERBS*.

S. minor.—This is a pretty pink species flowering in July, and growing 6 ins. high.

S. peregrina (Syn. *S. Sibthorpii*).—This is a tall-growing sort bearing violet-purple flowers from July to August, and growing about 1½ ft. in height.

SCUTICARIA.—See *ORCHIDS*.

SEA ARROW-GRASS (*Triglochin maritimum*).—See *ARROW-GRASS*.

SEA BUCKTHORN.—The genus HIPPOPHAE. See *SHRUBS*.

SEA HOLLY (*Eryngium maritimum* and the genus ERYNGIUM).—See *ERYNGIUM*.

SEA LAVENDER (*Statice*. Nat. Ord. Plumbaginaceæ).—A very large number of Sea Lavenders have been described, though some of them are rather weedy. Those we mention below are useful for the front portions of the herbaceous or rock border, and also for the rock garden. They are easy plants to cultivate if we neglect the evergreen greenhouse and half-hardy perennial forms, and are easily propagated by seeds sown at the usual time for perennials, or by division of the roots in the autumn or spring. They require common light garden loam and may be successfully planted from November to March. Weeding out undesirables, we recommend the following:—

Statice alpina.—This is now considered synonymous with *Armeria alpina*, which see.

S. Ararati.—This has now been re-named *Acantholimon glumaceum*, which see.

S. auriculaefolia.—This is a pretty dwarf blue sort flowering in July and August. It only grows 6 ins. high.

S. eximia.—Two forms of this are offered. One has white flowers and the other pale rosy-purple or lilac. Both bloom in August, and average 12–18 ins. high.

S. Gmelini.—This bears flowers of the deepest blue in July and August, on plants 12–24 ins. high.

S. incana.—This is an attractive sort with deep pink or even reddish flowers. It blooms in July and August, and only grows 12 ins. high.

S. latifolia.—This is the most favourite sort of all, with its enormous crop of blue flowers and delightful foliage. Its flowering period extends from May to August, and its height averages 12–24 ins.

S. Limonium. — This and its variety *Smithii* bear attractive blue and rosy-violet flowers respectively. They bloom from July to September, and average 12–24 ins. in height.

S. sinuata.—This is quite hardy in warm localities, and is a useful sort bearing purple and yellow flowers in August, and growing 12 ins. high.

S. Smithii.—This nurserymen's sort is not a species. It is the variety *Smithii* of *S. Limonium*, described above.

S. speciosa.—This is quite hardy in warm localities, and its white flowers borne in July and August, on plants 12–18 ins. high, are distinctly useful.

S. Suworowi.—This is a useful rose-pink sort blooming from June to September, and growing about 18 ins. high.

SEA MATWEED (*Ammophila arundinacea*).—See AMMOPHILA.

SEA ONION (*Scilla verna*). — See SCILLA.

SEA PINK.—See ARMERIA.

SEA ROCKET (*Cakile maritima*. Nat. Ord. Cruciferæ).—This is a hardy annual of very easy culture, but not so beautiful as common ROCKET, which see. It bears purple flowers in June or July, and grows 9 ins. high. The best time to sow it is early April.

SEA SAND.—See SAND.

SEA SPEAR GRASS (*Glyceria maritima*).—See GLYCERIA.

SEA SPLEENWORT (*Asplenium marinum*).—See FERNS AND FERN GARDENING.

SEAFORTHIA.—See under ARCHONTOPHŒNIX in PALMS.

SEAGULL MANURE.—See POULTRY MANURE.

SEAKALE (*Crambe maritima*. Nat. Ord. Cruciferæ).—The cultivation of this delicious vegetable under glass is dealt with elsewhere in this book; this article deals only with the outdoor treatment of the crop

preparatory to lifting for forcing purposes. A stock may be raised in two ways, either of which calls for little trouble or expense.

Plants from Seed.—Raising from seed is perhaps the easiest way for the beginner, although where forcing crowns are desired at the earliest possible date, the second method here detailed should be adopted.

The seed should be sown in a portion of heavily manured and deeply dug ground as early in April as possible; selecting an open site, and if more than one row is to be sown, allow not less than 15 ins. between each, the drills being made about 2 ins. deep. The seed is large and usually germinates very well, so this is best dropped in pairs at intervals of 9 ins. up the drill; overcrowded rows with their attendant evils may thus easily be guarded against. Where both these seeds develop into plants, the weaker should be removed before it gets many inches out of the ground, care being taken not to loosen the one remaining. The subsequent treatment consists of weeding and hoeing, and, if very dry, giving water in goodly quantities in order that growth may not be arrested.

Early the following spring, transplant into other deep rich soil, not less than 15 ins. apart each way. Weeds must again be kept in check, and both clear water and liquid manure freely supplied throughout the summer.

Plants from Cuttings.—Propagation from cuttings of the old roots is the plan most generally adopted. This entails less labour and certainly gives good forcing crowns a year in advance of those from seed.

Cuttings about the thickness of a man's little finger or stout pencil should be taken early in the winter, always removing the portion nearest the stem quite level, the other in a slanting position, this being necessary to distinguish the top from the bottom. The length of these cuttings is not important; anything from 3–6 ins. will answer equally well. When prepared as indicated, tie up in bundles of a dozen or so, and store nearly level with the tops in boxes filled with dry earth, standing these in a shed safe from severe frosts.

By early spring each of these cuttings will be showing numerous miniature heads round the outside of the top. All excepting the two strongest of these should be removed, and planting in the open done as advised for one-year-old seedlings, covering the crown with a few inches of fine soil. Later on, when the stronger of the two shoots can be discerned, pull away the weaker. By very liberal feeding with manure water and an occasional light dressing of common salt, encourage the plants to form strong forcing crowns the first season. It should be pointed out that it is only where the rows are fed on the liberal scale advised that such crowns are obtained, plants left to themselves being of little use until two years old.

If not required for forcing, the whole batch may be allowed to remain untouched until the early spring, when permanent beds may be formed in the open. The plants may be set in rows 2 ft. apart and 18 ins. asunder, which method is a good one to adopt where early produce is to be grown with the aid of long wooden troughs and plenty of dry leaves and manure. Where it is intended to use special Seakale pots, plant three strong crowns to form a triangle at 1 ft. apart, allowing 3 ft. between each batch of three. Make a point of removing all flower spikes before the flowers open. If cooked, these stems make a most excellent green vegetable.

Early produce may also be had from plants in the open by covering the strongest of the crowns with a good heap of coal ashes early in March; large cracks in the ashes will indicate the growth of the kale beneath. After forcing plants in the open, plenty of rich manure should be placed around the crowns, and ample moisture provided during the season, allowing two years before the same clumps are again forced into growth.—F. R. C.

SEASIDE GARDENS: Plants and Trees for.—The gardener who has spent most of his life in inland gardens will find, on being transferred to the sea-coast, that he is very much "at sea." In many cases, plants that would have to be carefully protected through the winter away from the sea would flourish on the sea-coast; in other cases, plants that would survive many degrees of frost inland would be withered out of recognition if exposed to a gale blowing from the sea and laden with salt spray.

Plants growing by the sea are wonderfully immune from damage by frost. Dahlias, for instance, may successfully withstand four or five degrees of frost in a sheltered spot on the sea-coast, although the slightest frost will terminate their existence for that year in inland gardens.

To those who are fortunate enough to possess a garden by the sea, the formation of a rock garden is strongly recommended. Its delights are never-ending, and by careful planning and arrangement it can be formed to afford protection to numerous little gems of the floral world whose home is among the Swiss Alps or in the Pyrenees. The intense pleasure to be derived even from a small rock garden is inestimable. It is quite possible to have rock plants in flower from January to December. Most alpines succeed well in seaside gardens in suitable positions.

With regard to Shrubs and Trees, every care should be taken to make them perfectly secure by careful staking and tying; and in preference only subjects of a dwarf, sturdy nature should be planted, since they will require less staking and will withstand the wind far better.

On exposed parts of the sea-coast it is advisable, when laying out a garden, to plant a belt of trees, such as *Pinus austriaca* or other hardy subjects, which will eventually afford protection for the more delicate plants.

Lastly, the best advice that can be given is to treat all subjects generously in the way of manure, and not to ignore their special likes and dislikes. Seaside gardening is, as a rule, regarded as gardening under adverse conditions, but if the various subjects are well looked after, there is no reason at all why they should not be a lasting success, if not indeed "a joy for ever."

What to Grow.—The following lists of plants suitable are given as a result of many years' experience of seaside gardening, and although exposed to severe north and north-east gales, it has been possible, by careful protection, to grow beds of such things as Schizanthus, Tuberoses, etc., and to have Roses in bloom out of doors to grace the dinner-table on Christmas Day.

ANNUALS.—The following succeed very well, and may be sown outside in mid-April :—

Alyssum lilacina, mauve.
A. Little Dorrit, white.
Anagallis coccinea (Scarlet Pimpernel).
A. caerulea (Blue Pimpernel).
Brachycome iberidifolia, blue.
B. iberidifolia alba, white.
Calendula officinalis Orange King.
Convolvulus minor, various shades of blue and white.
Dimorphotheca aurantiaca, orangé.
Godetia Crimson Glow, crimson.
Leptosyne maritima, yellow.
Limnanthes Douglasii, yellow and white.
Linum grandiflorum rubrum, scarlet.
Lupinus nanus, blue and white.
Nemophila insignis, blue.
N. insignis alba, white.
Phacelia campanularia, gentian blue.
Saponaria calabrica Scarlet Queen.
Silene pendula compacta, rose.
Venus's Looking Glass, blue and white.
Virginian Stock, many colours.
Viscaria cardinalis, deep scarlet.
V. oculata, pink.

HERBACEOUS PERENNIALS.—The following are most suitable :—

Acanthus mollis, white and rose.
Achillea Ptarmica The Pearl, white.
Aconitum Fischeri, blue.
Anchusa italica Dropmore and *Opal*, dark blue and pale blue.
Anemone japonica, many colours.
Aster Amellus (dwarf varieties), in blue and white.
Astrantia major, pink.
Buphthalmum salicifolium, yellow.
Campanula celtidifolia, milk-blue.
Centranthus ruber, in crimson, rose, and white.
Coreopsis grandiflora, yellow.
Delphiniums (dwarf varieties), blue.
Erigeron speciosus, deep mauve with yellow centre.
Eryngium alpinum, metallic blue.
Fuchsia exoniensis, scarlet and purple.
F. gracilis, scarlet and purple.
F. Riccartoni, scarlet.
Funkia in variety, many colours.
Gaillardia in variety, many shades of crimson and yellow.
Galega Hartlandi, blue and white.
G. officinalis, blue and white.
Glaucium flavum, yellow.
Gypsophila paniculata, white.
Hedysarum coronarium, carmine.
Helenium Hoopesi, orange.
H. pumilum magnificum, dwarf, yellow.
Helleborus niger in variety, white and purple.
H. orientalis, mixed colours.
Hemerocallis in variety, orange-yellow, red, etc.
Heuchera in variety, pink, red, and white.
Kniphofia (dwarf hybrids), in variety of colours.
Phlox decussata (dwarf varieties), in many colours.
Romneya Coulteri, pure white with yellow stamens.
Rudbeckia Newmani, yellow.
Scabiosa ochroleuca, sulphur yellow.
Spiraea Aruncus, cream.
Statice latifolia, blue.

ROCK PLANTS.—The following succeed splendidly :—

Acaena microphylla, crimson burrs.
Acantholimon glumaceum, rose.
Achillea ageratifolia, white.
A. rupestris, white.
Æthionema grandiflorum, rose.
Alyssum saxatile, yellow.
Androsace sarmentosa, rose.
Anemone Pulsatilla, pale purple.
Antirrhinum sempervirens, creamy white.
Arabis albida, white.
A. aubrietioides, pink.
Arenaria balearica, white.
A. montana, white.
Armeria latifolia, rose.
Aster alpinus, purple.
Aubrietia in great variety, pink, purple, etc.
Campanula carpatica, fragilis, garganica, muralis, and many other useful varieties in shades of blue and white.
Cheiranthus Allionii, orange-yellow.
Coronilla cappadocica, yellow.
Crucianella stylosa (Syn. *Phuopsis stylosa*) (trailer), pink.
Dianthus caesius, deltoides, hybridus, and *neglectus*, in range of colour.
Dryas octopetala, white.
Erigeron mucronatus, white, changing to red.
Erinus alpinus, white to purple.
Gentiana acaulis, bright blue.
Gypsophila cerastoides, white.
G. repens, white.
Helianthemums in variety, with their range of colour.
Hippocrepis comosa (trailer), yellow.
Hypericum repens, yellow.
Iberis saxatilis, white.
I. sempervirens, white.
Leontopodium alpinum (Edelweiss), silvery foliage and white flowers.

Linaria alpina, hepaticaefolia, and *pallida,* in range of colours.
Linum flavum, golden-yellow.
L. narbonense, blue.
Lithospermum prostratum Heavenly Blue, blue.
Lychnis haageana, various shades of crimson, red, etc.
Mentha Requieni (sweet-scented carpeter), purple.
Morisia hypogaea, yellow.
Œnothera macrocarpa, yellow.
Onosma tauricum, yellow.
Oxalis enneaphylla, white.
Papaver alpinum, in range of colour.
Phlox subulata, in many varieties, and in range of colour.
Plumbago Larpentae (Syn. *Ceratostigma plumbaginoides*), violet-blue.
Polygonum affine (Syn. *P. Brunonis*), rose.
P. vaccinifolium, rose-pink.
Primula marginata, purple and rose.
P. viscosa, rosy-purple.
Ramondia pyrenaica,[1] lilac.
Saponaria ocymoides (trailer), pink.
Saxifraga, most varieties, in range of colour.
Sedum, most varieties, in range of colour.
Sempervivum, most varieties, in range of colour.
Silene alpestris, white.
S. Schafta, pink.
Thymus lanuginosus, purple.
T. Serpyllum coccinea, scarlet.
Tunica Saxifraga, pink.
Verbena chamaedryoides (trailer), scarlet.
Veronica gentianoides, pale blue.
V. rupestris, blue.
V. saxatilis, blue.
Viola cornuta, blue.
V. gracilis, blue.

SHRUBS.—The following may well be grown, and those marked with a star are useful for walls and trellises :—

**Ampelopsis,* in variety.
Arbutus Unedo.
**Azara microphylla.*
Berberis Darwinii.
B. stenophylla.
Buddleia globosa
B. variabilis veitchiana.
Choisya ternata.
Cistus ladaniferus.
Colutea arborescens.
C. cruenta.
**Cotoneaster microphylla.*
Diplopappus chrysophyllus.
Escallonia langleyensis.
E. macrantha.
E. rubra.
Euonymus japonicus.
**Forsythia suspensa.*
Garrya elliptica.
Griselinia littoralis.
Hydrangea hortensis.
Hypericum calycinum.
H. moserianum.
**Jasminum nudiflorum.*
**Kerria japonica fl. pl.*
Leycesteria formosa.
**Magnolia grandiflora.*
M. Halleana.
Olearia Haastii.
O. macrodonta.
O. stellulata.
Osmanthus, in variety.
**Polygonum baldschuanicum.*
Skimmia japonica (male and female).
Spiraea discolor.
Tamarix gallica.
Ulex hispanica.
Veronica Andersoni.
V. Autumn Glory.
V. salicifolia.
V. Traversii ; etc.

TREES.—The list of trees that really flourish by the sea is very limited. The following stand the winds remarkably well :—

Acer Pseudo-platanus (Sycamore).
Alnus glutinosa (Alder).
Pinus austriaca (Austrian Pine).
Pyrus Sorbus (Service Tree).
Quercus Cerris (Turkey Oak).
Ulmus montana (Wych Elm).

SEASIDE HARD GRASS (*Lepturus cylindricus*).—See *LEPTURUS.*

SEASIDE SPURGE (*Euphorbia Paralias*).—See *EUPHORBIA.*

SEATS.—See *GARDEN FURNITURE.*

SEAWEED AS MANURE.

Why is seaweed not used more as a manure ? This is a question one cannot help asking with the increasing scarcity of stable and farmyard manure. Probably the answer is that gardeners do not use it largely because most of them do not know how to do so to the best advantage. Hence the following suggestions may prove useful.

[1] This requires a north aspect.

Burning Seaweed.—Where there are immense tracts of seaweed available for gathering, as is the case in some parts of the east coast and in Scotland, the material might well be burnt, as garden rubbish is burnt for the sake of the salt and potash it contains. The resulting ash is similar to wood ashes, but is sometimes known as KELP, and may be used at the rate of 4 oz. per sq. yd. for most crops.

Humus from Seaweed. — The above process is very wasteful and should only be adopted where there is a large excess of the weed. In other cases a few tons should be collected on the beach in the early autumn, and carted up to the garden to be made into a stack on similar lines to a manure stack. The material may be piled up alone, or mixed with an equal quantity of hot fermenting stable dung or vegetable humus. If it is stacked alone it takes longer to rot, and should not be disturbed for six months, or, better still, twelve. It will then have turned into a soft, mild humic manure not unlike old cow manure, but of course much more salty. If it is stacked with hot stable manure, the material will be ready for digging in after being stacked for two or three months, while if mixed with vegetable refuse a period twice as long is required for surface digging-in, though for trenching the material may be used after being stacked for about eight weeks.

Crops Benefited by Seaweed.—All salt-loving crops are greatly benefited by a timely application of seaweed manure. It is most excellent for use in pea, bean, celery, and leek trenches and for top-dressing asparagus beds. It is not so suitable for potatoes, as these object somewhat to its salty nature.

E.

SECALE (Nat. Ord. Gramineæ). One species of this genus is sometimes grown as a green manuring crop in gardens. This, *S. cereale* (Syn. *S. montanum*), is the RYE well known to farmers, from which black or rye bread is made abroad. It must not be confused with RYE GRASS and ITALIAN RYE GRASS mentioned in our notes on the genus *LOLIUM*, from which it is quite distinct though used for the same purposes in the garden.

SÉCATEURS.—See *GARDEN TOOLS*.

SEDGE.—See *CAREX*.

SEDIMENTARY ROCK.—See under KINDS OF ROCKS in *GARDEN GEOLOGY*.

SEDUM (STONECROP. Nat. Ord. Crassulaceæ).—These plants comprise a large number of valuable garden subjects, and are so well-known that little is necessary by way of description. All are characterised by succulent, or fleshy foliage, this enabling them to resist long periods of drought without injury. They are valuable for dry positions. The taller species are excellent for borders, beds, or rockwork, while the dwarfer sorts are of high value for carpeting purposes, such as carpet bedding, or for covering spaces occupied by early-flowering bulbs. Many of them will flourish on roofs or dry walls, and flower even better there than in what would appear happier conditions. Cultivation is simple. The taller Stonecrops appreciate a fairly good soil, and the dwarfer species are better for the drier places. A considerable number flower more freely if there is an admixture of lime in the soil. This can be supplied by the addition of some old mortar, broken small. It is surprising the difference this makes in the case of certain subjects, such as our native *S. acre*. Pro-

pagation is remarkably easy. Pieces of branches broken or cut, or little bits of the tufted species inserted in sandy soil, are almost certain to root freely. Division is easily performed with many of the Stonecrops. Some species are readily raised from seeds sown in sandy soil in pots or pans in spring, and the plants set in their permanent positions in autumn or the following spring. The greater number of those named are hardy perennials, but there are a few pleasing annuals, among which *S. coeruleum*, the Blue Stonecrop, deserves special mention as a gem for rockeries. Sow this where it is to bloom in April.

Selection of Sorts.

Sedum acre.—The Biting Stonecrop, with yellow flowers from June onwards. Height, 2–3 ins. *S. a. aureum* has yellow leaves; *S. a. elegans* has silvery tips; and *S. a. major* is larger in all its parts.

S. Aizoon.—Yellow flowers from June onwards. Height, 1 ft.

S. album.—The Worm Grass, with white flowers from June onwards. Height, 3–6 ins.

S. amplexicaule.—Yellow flowers in June. Height, 6–9 ins.

S. Anacampseros.—The Evergreen Orpine, with purple flowers in July. Height, 1 ft.

S. anglicum.—Whitish flowers in July. Height, 2 ins.

S. anopetalum.—Greenish-yellow flowers in July. Height, 6 ins.

S. arboreum.—A tender sort with white flowers in July. Height, 6–12 ins.

S. asiaticum.—Yellow flowers in July. Height, 6–12 ins.

S. beyrichianum.—White flowers in July. Height, 2 ins.

S. brevifolium.—This sort suffers from winter wet, and bears white flowers in July. Height, 2 ins. *S. b. Pottsii* has fine foliage.

S. coeruleum.—The Blue Stonecrop, with pale blue flowers from July onwards. It is an annual. Height, 2–4 ins.

S. dasyphyllum.—Pinkish flowers in July. Height, 2–3 ins. *S. d. glanduliferum* is similar to the above.

S. Ewersii.—Pink flowers in August. Height, 6 ins. *S. E. turkestanicum* has red flowers.

S. Fabaria.—Syn. *S. Telephium.*

S. hispanicum (Syn. *S. glaucum*).—Whitish-pink flowers in July. Height, 3–4 ins.

S. hybridum.—Yellow flowers in August. Height, 1 ft.

S. japonicum.—Yellow flowers in July. Height, 6 ins.

S. kamtschaticum.—Yellow flowers in August. Height, 4–6 ins.

S. lydium.—Pinkish flowers in June. Height, 1–2 ins.

S. Maximowiczii.—Yellow flowers in July. Height, 1 ft.

S. maximum.—There are several varieties of this bearing white and red flowers in July. Height, 1–2 ft.

S. middendorfianum.—Yellow flowers in June. Height, 1 ft.

S. obtusatum.—Yellow flowers in July. Height, 6 ins.

S. obtusifolium.—White flowers in June. Height, 4–6 ins.

S. oppositifolium.—White flowers in July. Height, 6 ins.

S. populifolium.—White or pinkish flowers in August. Height, 6–10 ins.

S. pruinatum.—Yellow flowers in July. Height, 1 ft.

S. reflexum.—The Stone Orpine, with yellow flowers in July. Height, 6–8 ins. There are other varieties which vary slightly. The most distinct is *cristatum.*

S. roseum (Syns. *S. Rhodiola* and *Rhodiola rosea*).—The Rose Root, with rose flowers in June. Height, 9–12 ins. There are several varieties of little consequence.

S. rupestre.—Yellow flowers in

July. Height, 6 ins. *S. r. monstrosum* is distinct and curious.

S. sarmentosum.—Greenish-yellow flowers in July. Height, 6 ins. *S. s. variegatum* has leaves striped white.

S. Sieboldii.—This is a tender sort in some parts. It has pink flowers in August. Height, 9–12 ins. *S. S. mediopictum* has leaves blotched white.

S. spathulifolium.—Yellow flowers in June. Height, 3 ins.

S. spectabile.—Pink flowers in September. Height, 12–18 ins. *S. s. atropurpureum* has red flowers.

S. stoloniferum (Syn. *S. spurium*). — Pink flowers in July. *S. s. album* has white flowers, and *S. s. splendens* red flowers.

S. telephioides.—Pink flowers in June. Height, 6–12 ins.

S. Telephium (Syn. *S. Fabaria*).—The ORPINE, with pink, purple, or white flowers from July onwards. Height, 12–18 ins. There are numerous varieties of this, including *Fabaria.*—S. A.

SEED : AMOUNT REQUIRED.

The following table, taken by permission from *Food Production Leaflet, No.* 8, published by the Ministry of Agriculture, gives the amount of seed required for planting a 10–12 sq. rod allotment :—

KIND OF CROP.	LENGTH OF ROW.	SEED REQUIRED.
Beans, Broad (2 rows)	50 ft.	½ pt.
Beans, Dwarf (2 rows)	50 ,,	¼ ,,
Beans, Runner (2 rows)	50 ,,	½ ,,
Beet, Globe	100 ,,	¼ oz.
Beet, Long	100 ,,	¼ ,,
Beet, Spinach	100 ,,	¼ ,,
Broccoli, Early (60 plants)	...	1/16 ,,
Broccoli, Late (60 plants)	...	1/16 ,,
Broccoli, Sprouting (125 plants)	...	⅛ ,,
Brussels Sprouts (125 plants)	...	⅛ ,,
Cabbage, Autumn (125 plants)	...	⅛ ,,
Cabbage, Spring (125 plants)	...	⅛ ,,
Carrot, Intermediate	75 ft.	⅛ ,,
Carrot, Long	75 ,,	⅛ ,,
Cauliflower, Early (60 plants)	...	1/16 ,,
Cauliflower, Late (60 plants)	...	1/16 ,,
Celery (125 plants)	...	1/32 ,,
Kale, Cottagers (125 plants)	...	⅛ ,,
Kale, Curled (125 plants)	...	⅛ ,,
Leek	90 ft.	⅛ ,,
Lettuce, Cabbage	60 ,,	⅛ ,,
Lettuce, Cos	60 ,,	⅛ ,,
Onion, Autumn	120 ,,	¼ ,,
Onion, Pickling	45 ,,	¼ ,,
Onion, Spring	120 ,,	¼ ,,
Parsnip	75 ,,	¼ ,,
Pea, Dwarf (2 rows)	40 ,,	½ pt.
Pea, Tall (2 rows)	40 ,,	½ ,,
Savoy Cabbage (125 plants)	...	⅛ oz
Spinach	120 ft.	½ ,,
Spinach Beet	100 ,,	¼ ,,
Turnips, Spring	75 ,,	⅛ ,,
Turnips, Summer	75 ,,	⅛ ,,
Vegetable Marrow	...	12 seeds.

SEED : AVERAGE GERMINATION OF. The following is the average percentage germination of all the more important vegetable seeds, taken by permission from *Food Production Leaflet, No.* 8, published by the Ministry of Agriculture. It is very important to all gardeners, especially those requiring definite numbers of plants for special purposes. Thus, if a thousand tomato plants are needed, it is not enough to sow 1000 seeds, as the average germination is only 80%. Calling 80% $\frac{4}{5}$ of 100, the number of seeds required is

$$\frac{5}{4} \text{ of } 1000 = \frac{5}{4} \times \overset{250}{\cancel{1000}} = 1250.$$

In exactly the same way the other percentages may be calculated; thus, 75% is $\frac{3}{4}$ of 100, so if a seed germinates up to 75% and 1000 plants are required, you will have to sow $\frac{4}{3}$ of $1000 = 1333\frac{1}{3}$, or 1334 seeds.

VEGETABLE.	PER CENT.	VEGETABLE.	PER CENT.
Bean, Broad	90	Leek	60
Bean, French	90	Lettuce	88
Bean, Kidney	90	Marrow	80
Bean, Scarlet Runner	90	Mustard	80
Beetroot	70	Onion	75
Broccoli	80	Parsley	50
Cabbage	80	Parsnip	25
Carrot	55	Pea	80
Cauliflower	80	Pumpkin	75
Celery	50	Radish	80
Chicory	80	Salsafy	90
Cress	80	Spinach	68
Cucumber	80	Tomato	80
Kale	80	Turnip	75
Kohl Rabi	80	Vegetable Marrow	80

SEED SAVING.

What are the ideal conditions at which to aim in seed saving, either by the small or the large grower? They may be considered under three heads: (1) Fruits; (2) Vegetables; (3) Flowers.

Fruits.—It is well known that the seeds of many fruits such as apples, cherries, pears, plums, etc., seldom reproduce types anything like as good as the parent: that is to say, if they have been selfed or fertilised with their own pollen; but show a great tendency to revert to the wild parents, and many varieties will refuse to fertilise with their own pollen. Definite crosses must be effected by removing the stamens from the flowers before the blossoms have fully opened, and conveying pollen from another variety to the stigmas of those flowers from which the petals have been removed. After the operation the flower should be bagged and marked. The pips and stones may be removed from the fruits when ripe and kept in sand until they can be sown. The sand should be dry and kept in a cool place. Seeds of soft fruits, such as gooseberries, raspberries, and strawberries may be removed from the fruits with a knife or washed out and sown immediately. Seeds of cucumbers, tomatoes, and vegetable marrows which are really fruits although classed as vegetables should be washed out after care has been taken to select the finest and ripest fruits true to the type of the variety. If more than one variety of tomato is being grown in the same house there is again danger of crossing, and steps to prevent this must be taken by protecting the selected flowers. The seed when clean should be slowly dried in the sun, and stored

away in a cool, dry room, until sowing time arrives. In the case of cucumbers and marrows the fruits should be artificially pollinated and allowed to get dead ripe, when they may be cut open and the seed extracted and stored in packets or bags. The same applies to melons, and it is desirable that seed should only be saved when each variety is grown separately.

Vegetables.—Seed may be saved of beet, carrot, and parsnip when one variety only is grown in the garden. Good equal-sized roots true to type should be selected first of all, and these roots should, in the case of beet and carrots, be stored in a frost-proof shed for the winter, and planted out in the spring when the danger of severe frost is past. Not less than 18 ins. between the rows and 15 ins. between the roots should be left, and wider planting is desirable if space will admit. In the case of parsnips the selected roots may be planted at once as they will stand the winter quite well. The following season they will throw up strong stems which will branch. The parsnip and carrot will produce what are termed "crown" or "king" heads, and lateral heads, *i.e.* side heads. The crown or king heads are first ripe and the usual custom is to cut them and place them in bags. The lateral heads are harvested later by cutting off the entire stem and stacking or housing them until they are dry, when the seed may be threshed or beaten out and dressed.

The seed from the "king" heads is the largest and finest and would be shed in the case of parsnips before the laterals were ripe. It is well to add that parsnip seed deteriorates very rapidly and should not be kept for a second season. Carrot seed can nowadays be dressed so as to remove the appendages and obviate the sowing with sand to obtain even distribution. Beet seed is harvested by cutting the entire stem and laterals, putting into "shock" or "stook," and eventually stacking and storing until it can be threshed. When the seed of only a few plants has to be dealt with, as in the case of the amateur, the threshing may be done with a flail or mallet.

The Cabbage Family.—Seeds of all the plants of this family must be harvested quickly before the pods burst. It is then shocked and later stacked, after which it may be threshed during the winter. All the plants of this family are readily cross-fertilised by other varieties of the same family and by cruciferous weeds; they are visited by bees and largely patronised by most flies; thus the risk of crossing is very great. It is difficult to see how pure stocks can possibly be secured by the allotment holder or private gardener unless special precautions are taken to protect them from insects and foreign pollen. The seed of this family is easily kept in a dry storeroom and does not readily deteriorate in germinating capacity even if kept for several seasons.

Other Crops.—Fine types of parsley, if selected for seeding, should be protected by bagging before the heads are in bloom, cut and stored when dry, and threshed out. On a large scale the crop must be very carefully "rogued."

Celery, lettuce, and radish can be quite readily seeded if the precautions already referred to are taken.

Onions are seeded by selecting good average typical bulbs and planting in March. Each bulb should make from 3–5 flower heads, which are usually supported by ropes run along the rows. When the heads begin to ripen they are often cut with the upper portion of the

stem and inserted in the cup, or basal part of the flower stem. This keeps them upright and hastens ripening when they are later hung in bunches in sheds or granaries with sheets spread on the floor to catch falling seed. Leeks can be seeded in the same fashion, and the seed when properly matured will keep for several seasons, although the vitality and percentage of germination gradually go down.

PEAS AND BEANS.—These are the easiest of all crops from which to save seed, as there is no danger of cross fertilisation. The best and most uniform pods are selected, and these allowed to become nearly ripe when they are gathered, dried in the sun, shelled, and stored in paper or Hessian bags till required for use. The first crop of pods produced should be selected for seed purposes, not the pods left on the haulms after picking and marketing a portion of the crop, as these pods are usually of inferior quality.

POTATOES.—These may be raised from seed by special crossing, or the ordinary plums (fruits) may be picked in the autumn and placed in small tin boxes amongst dry sand after holes have been pierced in the lids to admit air and allow moisture to escape. If the small tins are kept in a dry atmosphere all the winter, the fruits dry up and may be rubbed down in the spring and sown along with the sand. The saving of *Seed Tubers* is dealt with in our article on *SAVING SEED POTATOES*.

Flowers.—Annuals, biennials, and perennials may be seeded and selected by small growers as well as large. The same difficulty with regard to crossing has to be guarded against in many flowers, and when a good type has been secured, the plant to be seeded should be surrounded by fine muslin just as the flowers begin to open. If this be done the variety will come fairly true to type; for instance, the true type of *Antirrhinum Nelrose* can be retained if precautions against cross pollination are taken.

Ordinary herbaceous plants as a rule come fairly true from seed, though it is often policy to remove several of the weak capsules on plants which are being selected for seeding, and when the seed has become plump the capsules may be removed with a part of the stems, or the whole plant may be pulled up, placed in a paper bag, and hung from the roof of a dry shed or storeroom. Care must be taken that proper ventilation is given at the upper end of the bag to prevent moulding in the process of drying. Podded plants may also be removed in a green state if the seeds are fully developed, and the haulms or stems spread on the floor of a dry building or on shelves, or hung from the roof. The seed can then be extracted at leisure during winter. This applies also to vegetables such as peas, kidney and runner beans, etc. The seed should not be kept in a very warm room, otherwise it may become over ripened, in which case it will germinate very badly or take much longer to come above ground. On the other hand there must be no excess of moisture in the atmosphere, otherwise the cuticle will become soft and the reserve material in the seed will begin to change and premature germination or decay will follow. When once this change has begun in a seed it is impossible to check it effectively, and if the seed is not in a position favourable for germination, fermentation will set in and the seed will die.

Although expert private gardeners can often successfully save their own seed, the practice in the case of small growers and allotment holders is not to be whole-heartedly recommended.

In normal times good seed can be obtained at a reasonable price, and the saving and selection had much better be left in the hands of reputable seed firms, who, through long experience, have specialised and become expert in the process. On the other hand the crossing and raising of new varieties should be encouraged amongst all growers. In fact the horticulturist who, during his life, never tries to raise new seedlings of some class of garden produce is not worthy of the name, for the operation is interesting, educative, and ennobling. See also our article on *Hybridising and Cross Breeding*.—G. P. B.

SEED SOWING.

This is a most important gardening operation, because on the proper method of sowing your seeds to a large extent depends whether you will have a good crop or a bad one.

There are a great many different kinds of seed, but when the fundamental principles of seed sowing are once grasped, no mistake may be made, even though you are about to sow many kinds with which you have had no previous experience.

First of all let us get to know the seed itself. Take a large one (the pea for example). When we examine it carefully, we find it has a more or less hard, tough skin (the *testa*). On removing this, we find a hard substance which can be divided into two halves (the seed leaves or *cotyledons*). Between these seed leaves we can see the little baby plant (or *embryo*).

The skin protects the seed leaves and baby plant. The former are simply a mass of cells filled with food material for the use of the baby plant when growth commences.

The conditions necessary to start the baby plant into growth (germination) are three in number :—

(1) Moisture.
(2) Heat.
(3) Air.

The moisture softens the skin and makes it porous, and some of it passes through and softens the hard substance in the cells of the seed leaves, and also the cells themselves. The necessary heat ensures that the food substances within the cells are changed into the suitable form of food for the little baby plant. And all growing plants require a sufficient supply of air to enable them to breathe, and they also extract part of their food (carbon dioxide) from it.

Now seeds are of various sizes, and must therefore contain varying amounts of food substances for the baby plant. Then all the food substances taken up from the soil by the roots of plants must pass up to the green leaves and there, under the action of sunlight, in combination with the carbon dioxide taken in from the atmosphere, they are manufactured into the substances which form the cell walls and all contents of the growing plant. We must see, therefore, that our seeds are sown at the proper depth, so that, before all the food substances stored up in each seed are used up, the little plant will have reached the surface of the soil and spread out its green leaves to the action of the sunlight, there to carry on the work of the growing plant.

With a knowledge of these fundamental principles, there should be no difficulty with regard to the sowing of any kind of our garden seeds.

There are two periods in the year when the conditions are ideal for the sowing of seeds—spring and autumn; though, of course, seed

may be sown throughout the summer, when the conditions are naturally suitable, although in a very dry summer it is often necessary to supply artificial measures to atone for nature's shortcomings. The conditions with regard to moisture and air are always practically the same, when there is a slight film of moisture round the particles of soil, but not sufficient to fill the pores between the particles of soil and reach the germinating seed. A good guide to determine if the soil is suitable with regard to moisture is to take a handful of it from the surface of the seed bed, and press it in your hand; then open your hand and if the ball just falls to pieces the soil is in the right condition for seed-sowing. If, however, it clings together in a solid mass it is too wet and should be allowed to dry further. The amount of heat required for successful germination depends on the nature of the seed itself. Some of the seeds of our garden weeds will germinate a few degrees above freezing-point; while the seeds of plants from tropical countries require a brisk bottom heat of from 60° to 70° F. to ensure germination. For the majority of our outdoor vegetables and flowers, from the middle of March to the middle of May and during August, there will be sufficient heat to ensure successful germination.

If it is desired to sow seeds for successional crops when the soil is very dry, the drills should be drawn in the usual way and then well watered before sowing the seed and covering up. Never water the surface of the soil after sowing and covering the seed, as, in all probability, the water will not reach the seed, but will "cake" the surface of the soil, and prevent the air from reaching the seed.

The nature of the growth of plants should be taken into account, with regard to the distance at which to sow the rows of seed, but room should always be left to work the hoe for weeding and conserving the moisture between the lines of plants. Rows of carrots, leeks, onions, parsley, etc., may be sown 1 ft. apart; while the stronger-growing plants, such as beetroot, parsnips, turnips, etc., should have from 15 ins. to 18 ins. between the rows, to give them room to develop.

In sowing any kind of seed the greatest care should be exercised not to sow it too thickly. It is a waste of seed, and when the little plants appear above the soil, the competition which goes on for the food substances available from the limited space occupied by the rootlets, and for the sunlight, weakens the plants considerably, with consequent bad effects on the crop. Always buy seeds of first quality and sow thinly, giving each plant plenty of room to develop in its early stages. This is very important with seeds sown in the greenhouse or frame. With too thick sowing and a humid atmosphere you simply invite attacks of disease, especially the damping off disease (*Pythium*).

For outdoor sowing the seed-bed should be brought to a fine tilth by raking over and breaking the clods. The ground should next be marked out for the rows the required distance apart. After this the line should be carefully set and the drills drawn the required depth, being very careful to have them perfectly level in the bottom to ensure uniform germination and a good crop. In order to make the seed go as far as possible, instead of sowing thinly all along the drills, drop four or five seeds at intervals of 3 ins. apart for onions and carrots, thinning out

when large enough, leaving one plant where each clump was; when they are large enough to use in soups or for salads, remove every alternate one, leaving the remainder 6 ins. apart to mature. For beetroot and parsnips drop four or five seeds at intervals of 7–9 ins. apart, thinning out when large enough, leaving one plant where it is to mature. [Very thin sowing is advised in the case of hardy flower seeds, especially for annuals.—EDITOR.]

The depth to sow seeds varies with their size. Calceolaria seed is so small that it should not be covered with soil. The surface of the soil in the pot or pan should be made quite level, and the seed sown thinly and pressed into the soil. The pot should then be covered over with glass and paper, until germination takes place. Wipe the moisture from the under side of the glass each morning. Poppy seed is also small and should only be covered with about a quarter of an inch of soil.

Turnip, carrot, leek, onion, lettuce, and similar seeds may be covered with 1 in. of soil. Radish, parsnips, beetroot, and such like may be covered with 1½ ins. of soil. Pea, lupine, and other large seeds may be covered with about 2–2½ ins. of soil. Broad beans, runner beans, etc., may be covered with 3 ins. of soil.

Some seeds germinate best as soon as ripe, for instance, clivias, while others, such as holly and hawthorn, take two years to germinate. These latter seeds may be mixed with moist sand, left for a year, and then sown in the ordinary way. Very hard seeds, such as some palms, may be chipped before sowing. Some hard seeds may also be steeped in tepid water for twenty-four hours before sowing as, for instance, the canna and sweet pea.

Seeds will retain their power of germination for varying periods, but the majority are better sown the year after harvesting. A few will retain the power for two, five, or seven years, and melons have successfully germinated after fifteen years, though this is very exceptional.

W. GD.

SEED TESTING.

The introduction in 1917 of the first Seed Testing Order, which involved the creation of a Government Seed Testing Station—located at present (October 1919) in London, but eventually to be permanently installed at Cambridge—was welcomed in England by the more advanced seed firms, who had long recognised the necessity of testing farm and garden seeds before despatching the same to their customers. The new measure had one great advantage, namely, it levelled up the method of testing and made it uniform. Before the Government Order was promulgated, however, the average sample of agricultural and horticultural seed had immensely improved in quality, especially during the last twenty years, more particularly as regards cleanliness and freedom from weed seeds, though the ordinary "market sample" remained a dangerous thing to handle on account of its impurities. This advancement had been achieved by the enterprise of firms who had, at heavy expense and from high motives of the importance of agriculture and horticulture to the community, laid down and constantly reconstructed their seed-cleaning machinery, so that when the Order in question was inaugurated seeds practically pure and of the highest germinating power were readily procurable in accordance with the rules subsequently enforced

by the Seed Testing Order. This Order is shortly to be improved and introduced into the House of Commons, where it will doubtless become incorporated as an Act of Parliament. Notwithstanding all this it must be admitted that, except in the case of hand-picked seeds, a perfect sample is not to be found in commerce. By "perfect" is meant a sample of seed in which every grain is of the variety stated. For instance, a sample of beet, cabbage, or carrot would have no extraneous matter either in the way of other seeds or impurities. But although a perfect sample is rarely to be met with, it is desirable that the percentage of seeds which are true to name of any particular kind should be ascertained as well as its germinating capacity. Briefly, therefore, samples of seeds are examined and tested with a view to determining their "purity" and "germination."

The Purity Test.—Considering this first, the points to be ascertained are:—

(1) Whether the seed is true to name.

(2) What other useful seeds are present.

(3) What the percentages of impurities such as sand, weed growth, husks, and inert matter amount to.

(4) Whether noxious weed seeds are contained in the sample.

A note in addition is made of the ripeness of the seed, its size, and whether broken or not.

The purity test is carried out by separating the four lots described above, which are weighed; lots 2–4 being added together to give the amount of impurities present, and this is subtracted from the total weight of seed taken. The remainder (by weight) is known as the "percentage purity" of the sample. For accurate results a chemical balance and minute weights are essential. The weight of the sample taken for this test varies from ½ oz. in the smaller seeds to 8 oz. for very large and heavy seeds such as broad and runner beans. The separation described is best carried out on a sheet of white paper with a piece of flat zinc about 6 ins. in length, ½ in. broad at the end and tapering to about $\frac{1}{16}$ in. at the top.

The Germination Test.—Although comparatively simple, it requires minute care and constant observation in order to obtain a true and satisfactory result. First of all a quantity of seed true to name must be obtained, and from this three or four lots, each containing a hundred seeds, are counted out. In doing this a proportion of small, medium, and big seeds are taken so that the sample is fully representative. Duplicate tests are invariably arranged in various ways on sand, flannel, filter-paper, blotting-paper, or other suitable materials. After the seeds are placed in the germination bed, they are either kept automatically moist, or a spray is systematically employed. Some seeds grow best in complete darkness, others prefer light or half-light, but there are so many influences which affect the germination test that it is undesirable to dogmatise on this question. The length of time in growth tests varies from ten days to three weeks or even longer.

Temperature is a most important item in all germination tests. As a general rule 20° C. (68° F.) is employed, while for some seeds it is advantageous to raise the temperature for several hours during the day to 30° C. (86° F.). Rapidity of germination is increased by this method. A constant and equitable temperature can be secured by placing the seeds in incubators heated by

electricity and controlled by switches or thermostats, the latter being preferable and more reliable.

Estimated Value and Apparatus.—The real value of the sample is often estimated. This is expressed as the product of the purity and germination. Thus, assuming the purity of a seed is 95%, germinative capacity 90%, its true value is $\frac{95 \times 90}{100}$, or 85·5%. In other words, from every 100 lb. of such a parcel of seed only 85½ lb. could be expected to grow.

It is of the utmost importance to recollect that in the examination of seeds there will occur in some samples small imperfectly ripened and "weathered" grains; others may have a green tinge; some, instead of a plump exterior, are shrivelled and of different colour from the usual type. Again, certain of the seeds may be slightly injured by the machinery in the process of cleaning. The microscope here plays an important part in seed testing, and is invaluable to the seed analyst in arriving at certain conclusions.

The apparatus necessary in a well-equipped seed testing laboratory, public or private, is great and varied. Chemical Balances, Diaphanoscopes, Incubators of varying construction in size and shape, Tweezers, Sieves, Dissecting Sets, Separators, Porous Trays, and the materials for germination tests already mentioned, are the chief, in addition to which a thorough knowledge of botany and the problems of plant life is, of course, essential.

Home Testing of Seeds.—Apart from the scientific methods of seed testing already mentioned, there are many ways in which readers may easily test at home the vitality and purity of any seeds they buy. Vegetable and flower seeds may be grown on blotting-paper, folds of flannel and felt, or in pots of sand or garden soil. The method is simple: first of all a hundred seeds are counted out, and carefully placed on or in the selected material, after which this is thoroughly moistened and the receptacle is then transferred to a warm, dark place. A record is taken, say every two days, of the number of seeds which have germinated, the material meanwhile being kept uniformly moist. It should be noted that sand and earth tests are not so satisfactory, as the seeds cannot be observed during their development. It is necessary that the amount of light, air, water, and heat given should be tolerably even—especially is the amount of moisture supplied to the seeds of the utmost importance. The chief point to remember is not to give too much water, otherwise damping or rotting off will set in.

There are several other so-called methods of home testing of seeds, such as by immersing the seed in water or by planting it in a mixture of quicklime and soil. None of these are reliable and cannot be considered legitimate; they are indeed often misleading, so no good purpose would be served by describing them here.

SEEDING AND TURFING. — See *LAWNS AND THEIR MANAGEMENT.*

SEEDLING RHODODENDRONS. — See under PROPAGATION in *RHODODENDRON.*

SEEDLINGS: MANAGEMENT OF.

The management of seedlings is not so easy as it sounds, and this many gardeners have found to their cost. It is quite easy to sow seeds, it is quite easy to set plants out in the garden, but it is not so easy to manage seedlings from the time they appear till the time they are

ready for bedding out. Below are a few hints on this work, which it is hoped will prove useful to all gardeners.

Much can be done as a preliminary by using very light soil, and sowing the seeds of whatever kind they may be very thinly. This, and very shallow sowing, will largely prevent the common evil of hundreds of small spindly seedlings appearing. The soil used should, generally speaking, have at least one-eighth part of sand in it, and one-quarter of its own volume is better. It should not be dressed with artificial manures, as these do not tend to produce strong healthy seedlings. Seed when small should be sown absolutely on the surface of the soil, and the seed boxes covered with a sheet of glass and brown paper.

When the seedlings appear they must at once be put where they can get all the light possible. The ideal position for indoor plants is a shelf within a foot of the glass of a greenhouse; or should they be in a frame, the ideal position is within 6 ins. of the frame lights. Frequently ventilation is absolutely essential in the management of most seedlings, as otherwise damping off will set in, and spindly growth will be exceedingly common.

The watering of seedlings is a great problem to gardeners. However, the rule is that they should not have water unless the soil is getting dry. A clear ring of the seed-pans or pots will show that water is required, but a dull heavy sound when they are tapped with a wooden mallet shows that water is not required. The greatest error in the management of seedlings is to over-water them, since all manner of evils may set in if this is done.

Thorough drainage of seed-pots, pans, and boxes is essential if strong seedlings are to be the result. Sometimes as much as one-quarter of the total amount in the pans is drainage. Plenty of holes must be drilled in the bottom of the boxes if these are to be used for the rearing of seedlings, and these covered with crocks first. Then cover the crocks with the rougher portions of the compost, to prevent the finer soil particles from being washed down into the crocks.

Early pricking out is advisable if strong seedlings are to be the result. As soon as the little plants have two or four leaves they should be carefully lifted with a small trowel or hand-fork, and planted out separately in other boxes, or if they are of a hardy disposition into a bed in the cold frame. The distance to prick them out will depend on the nature of the plant, and in any case this should not be less than 3 ins. Six inches apart each way will be needed for the stronger bedding plants. The soil, again, should be very light, and planting should be firm. One good watering immediately after pricking out should carry the seedlings on for a considerable time.

The care of seedlings out of doors is somewhat similar to that just described. Seed should, of course, be sown very thinly, and the seed-bed should have reasonable and careful preparation. Not the hottest part of the garden should be chosen, but, instead, a plot which is very lightly shaded, in order that the seedlings may get a chance from the start instead of being burnt up by undue sun heat.

Out of doors there are, of course, many enemies to face, chief of which are slugs and snails. These creatures can be kept in abeyance by the free use of lime, or, better still, some good soil fumigant. For extra special seedlings the soil

should be sterilised prior to planting, but this is usually too much trouble to be adopted largely. Watering of seedlings out of doors should not be done in hot sunshine, and should always be done with a very fine rosed can, to prevent the soil being washed away from the roots, or the plants being broken down by the shower from the rose. Warm water is better than icy cold water fresh from the tap.

Needless to say, throughout the seedling stage seed-beds should be kept scrupulously clean of weeds, as, if the plants have to fight a battle against weeds, they cannot be expected to form the sturdy stuff that they would do if they had not to contend with these enemies.

A word must be said in closing on the matter of feeding seedlings. Gardeners seem fond of giving the tiny plants patent fertilisers in large doses, and nothing could be less to their advantage. Providing that the soil is reasonably good, no artificial manures are in the least necessary, and harm will be the result if they are used. The only stimulant that can safely be applied is soot-water. All other fertilisers should not be used until the seedlings have ceased to be seedlings and become strong flowering plants or vegetables near to maturity.—E.

SELECTION.—See *HYBRIDISING AND CROSS-BREEDING.*

SELECTIVE ABSORPTION. — See *PLANT PHYSIOLOGY.*

SELENIPEDIUM.—See *ORCHIDS.*

SELF HEAL, or SELF-HEAL.— See *PRUNELLA,* also under PRUNELLA in *MEDICINAL HERBS.*

SELLIGUEA.—Now included in the genus GYMNOGRAMME, for which see *FERNS AND FERN GARDENING.*

SEMPERVIVUM (HOUSELEEK. Nat. Ord. Crassulaceæ). — This constitutes a most interesting genus of succulent plants, distinguished for their resistance to drought. Their thick, fleshy leaves are arranged in symmetrical rosettes, which are frequently of exquisite form and colouring. The greater number of those named are hardy, but in wet districts a few, especially those which have a charming cobweb-like tomentum on the rosettes, *e.g., S. arachnoideum,* require protection by glass from excessive moisture in winter. If these are planted in a wall in an almost vertical position, this protection will be unnecessary, except in a few very wet parts of the country. The Houseleeks look well in chinks between dark rocks, but often harmonise perfectly with limestone. They flower more freely if there is lime in the soil, but this is not an entire gain, as the rosette which flowers dies afterwards. Some propagate themselves rapidly by means of little offsets, and are easily increased by taking off the side rosettes, which root quickly in light soil. They can also be raised from spring-sown seeds. The uses of Sempervivums in gardens are many and varied. Some have been employed with much skill in carpet bedding, their symmetrical form, neat habit, and simple formality lending themselves to the effects desired. They prefer a sunny situation and light soil. Some plant them with a proportion of decomposed manure in the soil, but others object to this as attracting birds in search of worms, and inducing them to tear up the rosettes. *S. Tectorum* is the common Houseleek frequently seen on roofs.

The nomenclature of the genus is in a chaotic condition, but the names which follow are founded on those of the best authorities. On account of the vast number in commerce, only a selection of the

best and most distinct can be given.

SELECTION OF SORTS.

Sempervivum arachnoideum.—The COBWEB HOUSELEEK, with red flowers in June. Height, 4 ins. *S. a. barbulatum* has rose flowers. Six other good varieties bearing red flowers are *doellianum, Fauconetti, Hausmanni, Laggeri, piliferum,* and *webbianum.* Height, 4–8 ins.

S. arboreum.—A tender sort, with greenish-yellow flowers in July. Height, 6–9 ins. *S. a. atropurpureum* has purple foliage, and *S. a. variegatum* has foliage marbled cream.

S. arenarium.—Pale yellow flowers in June. Height, 6–9 ins.

S. arvernense.—Pink flowers in July. Height, 6–8 ins.

S. atlanticum.—Pale red flowers in July. Height, 1 ft.

S. Boisseri.—Red flowers in July. Height, 9 ins.

S. boutignyanum.—Rose flowers in July. Height, 8 ins.

S. Braunii.—Yellow flowers in July. Height, 6 ins.

S. calcareum (Syn. *S. californicum*).—Pale red flowers in July. Height, 10–12 ins.

S. canariense.—This is a greenhouse sort, with white flowers in June. Height, 1½ ft.

S. fimbriatum.—Red flowers in July. Height, 6–9 ins.

S. flagelliforme.—Red flowers in June. Height, 4 ins.

S. Funckii.—Red-purple flowers in July. Height, 6–9 ins.

S. glaucum.—Red flowers in July. Height, 6–12 ins. There are several varieties with little difference.

S. globiferum.—The HEN AND CHICKENS, with pale yellow flowers in July. Height, 3 ins. *S. g. sobboliferum* is similar to the above.

S. hirtum.—Pale yellow flowers in June. Height, 6–9 ins.

S. metallicum.—This has metallic foliage, and red flowers in July. Height, 8–10 ins.

S. mettenianum.—Rosy-white flowers in July. Height, 4–8 ins.

S. montanum.—Red flowers in July. Height, 6 ins.

S. tabulaeforme.—A tender sort, with yellow flowers in June. Height, 12 ins. *S. t. variegatum* has variegated foliage.

S. Tectorum.—The COMMON HOUSELEEK, with red flowers in July. Height, 9–12 ins. The best varieties of this are *Lamottei, Reginae-Ameliae,* and *Requieni.*

S. triste.—A sort with dark foliage and red flowers in July. Height, 6–9 ins.—S. A.

SENEBIERA (Nat. Ord. Cruciferæ). This is a genus of weedy plants of no garden value. Two species are sometimes offered. These, *S. Coronopus* and *S. pinnatifida* (Syn. *S. didyma*), are both popularly known as WART CRESS.

SENECILLIS.—Now included in the genus *SENECIO.*

SENECIO (Nat. Ord. Compositæ). The Groundsels or Jacobaeas have considerable garden value, but it is to the perennial border and the greenhouse species that we look especially for stately form and brilliant colouring. Nevertheless, and notwithstanding its ubiquitous relative the common wild Groundsel, there is at least one useful garden plant which is a hardy annual, namely, *Senecio elegans.* It was formerly used extensively as a bedding plant, and it is useful for this purpose because it continues to bloom all through the season provided plants are raised under glass in March and planted out in early May, 6 ins. apart each way. An outdoor sowing in April will give plants to flower in late summer and autumn. The double form is

far superior to the single, and the colours obtainable are white, through pink, salmon, and carmine, to purple and crimson. The height varies considerably, 9–18 ins. being the average.

Greenhouse Species.—These are numerous. They succeed under cool greenhouse treatment in light sandy loam and are preferably increased by cuttings. The following are a few of the best :—

Senecio argutus. — This bears yellow flowers about July. Height, 3 ft.

S. cruentus. — See article on CINERARIA.

S. fulgens.—This is a scarlet summer blooming sort about 2 ft. high.

S. grandiflorus (Syn. *S. venustus*). —This bears purple flowers from August onwards, and grows 1½ ft. high.

S. lilacinus.—This bears lilac and blue flowers from June onwards. Height nearly 2 yds.

S. macroglossus.—This is a yellow-flowered climber blooming in July. Height, 6–10 ft.

S. persicifolius.—This is a purple-flowered sort blooming in July. Height about 1 yd.

S. pubigerus.—This bears reddish flowers from mid-summer onwards. Height, 2 ft.

S. rosmarinifolius. — This bears yellow flowers in July. Height about 1 yd.

S. venustus.—Syn. *S. grandiflorus.*

Perennial Border Species.—These include some of the most attractive garden plants. They succeed with ordinary treatment for perennials in good soil in a sunny or lightly shaded site, are propagated by division of the roots in the autumn or spring, and may be successfully planted any time from November to March. We describe a few of the best species below :—

Senecio adonidifolius (Syn. *S. artemisiaefolius*).—This is a useful yellow sort, flowering from July onwards, and growing about 12 ins. high.

S. alpinus.—This also is yellow and is suitable alike for rock garden and border. It blooms from June onwards and grows 18 ins. high.

S. artemisiaefolius.—Syn. *S. adonidifolius*, which see.

S. carniolicus —This bears yellow flowers freely in the summer, and varies somewhat in height.

S. Cineraria (Syn. *Cineraria maritima*). — This, the DUSTY MILLER of popular gardens, bears yellow flowers freely from July to September, and averages about 2 ft. in height.

S. Clivorum.—This, so often offered by nurserymen, is not grown at Kew. It may be synonymous with *S. japonicus*, described below.

S. Doria.—This useful species bears yellow flowers in August, and averages about 4 ft. high.

S. Doronicum (LEOPARD'S BANE). —This is hardly distinct from *Doronicum austriacum.* It bears attractive yellow flowers in the spring and summer, and averages 1–3 ft. high.

S. Ewersii.—Syn. *S. alpinus*, which see.

S. jacquemontianus.—According to some authorities this is a synonym of *S. nemorensis* (described below). It is undoubtedly very similar to it.

S. japonicus.—This useful species bears yellow flowers in August, and averages about 1 ft. in height. The variety *macrantha* is specially good.

S. macrophyllus. — This useful taller species bears yellow flowers from July onwards, and averages 4 ft. in height.

S. nemorensis.—This bears yellow flowers from July onwards, and averages about 1 yd. in height.

S. paludosus (BIRD'S TONGUE).—This native species bears yellow flowers from July onwards, and averages 5 ft. high.

S. pulcher.—This bears attractive crimson-purple or yellowish-purple blooms in July, August, and September. Its height is about 1 yd.

S. sarracenicus (SARACEN'S CONSOUND).—This, which requires a damp site, bears yellow flowers from July onwards, and averages about 4 ft. high.

S. Smithii.—This is an attractive sort bearing pink flowers from July onwards. It grows about 2 ft. high.

S. uniflorus.—This dwarf sort is useful in the rock garden. It bears yellow flowers in July, and averages 3 ins. in height.

See also *SHRUBS*.

SENSITIVE FERN (*Onoclea sensibilis*). See *FERNS AND FERN GARDENING*.

SEQUOIA.—For the best species see *TREES*.

SERBIAN SPRUCE.—The same as SERVIAN SPRUCE.

SERIOLA.—Now included in the genus *HYPOCHOERIS*.

SERRADELLA (*Ornithopus sativus*). See *ORNITHOPUS*.

SERRAFALCUS.—Now included in the genus *BROMUS*.

SERRATULA (SAW-WORT. Nat. Ord. Compositæ).—Former species of this genus are now included under *Jurinea*, *Liatris*, and *Saussurea*, but we only mention the last two genera. Omitting the synonymous species, we are left with a number of annuals, biennials, and hardy perennials, but only the last section are worthy of much attention. These are of easy culture in ordinary soil and may be grown much as any other hardy herbaceous perennials, being planted in March, and propagated by root division or by seeds at the usual times. *S. coronata*, *S. heterophylla*, and *S. quinquefolia* are the three best species, bearing purple flowers in July, on plants 2–6 ft. high. *S. tinctoria* is the COMMON SAW-WORT—a plant of little merit. The type and its variety *monticola* both bear purple flowers from July to August, and grow 2–3 ft. in height.

SERVIAN SPRUCE (*Picea Omorica*). See *TREES*.

SERVICE-BERRY (*Amelanchier canadensis*).—See *SHRUBS*.

SERVICE TREE (*Pyrus Sorbus*).—See *TREES*.

SESELI (MEADOW SAXIFRAGE. Nat. Ord. Umbelliferæ).—This is a genus of hardy annuals, biennials, and perennials of no value in the ordinary garden, but often offered to and bought by unwary amateurs on account of its English name containing the word "Saxifrage." All bear white flowers about July, and average 1½–4½ ft. in height. *S. annuum* and *S. Hippomarathrum* are probably the best known species, the latter being the HORSE FENNEL.

SESLERIA (Nat. Ord. Gramineæ). This is a genus of coarse-growing grasses, hardy perennials of no value in the garden whatever. *S. argentea* (Syns. *S. cylindrica* and *S. elongata*) and *S. coerulea* are probably the best known species; the latter is the MOOR GRASS so familiar to ramblers.

SETARIA (BRISTLY FOXTAIL GRASS. Nat. Ord. Gramineæ).—This is a genus of hardy annual grasses of little value, which thrive in almost any kind of soil. *S. viridis*, the BOTTLE GRASS, growing 1–2 ft. high, is about the best. *S. italica*, popularly known as ITALIAN MILLET (not so tall), must be distinguished from the MILLET described in our article on *PANICUM*, and from the MILLET GRASSES mentioned in our articles on *MILIUM* and *SORGHUM*.

SEWAGE AS MANURE.

The recovery and utilisation of the fertilising properties of sewage have occupied much attention, especially since the establishment of special works for purifying the sewage of towns. Many calculations have been made of the loss of nitrogen and other products contained in sewage, and numerous attempts have been made to recover the manurial constituents. It must, however, be borne in mind that a large proportion of the fertilising value of sewage is contained in the liquid portion, and cannot be extracted economically, except where land can be irrigated directly with the liquid.

The solid deposited residues or sludges are therefore the only portion of sewage which can at present be usefully employed as manures on any extensive scale. Such sludges vary in character according to the system of treatment employed for the purification of the sewage.

Usually the heavier solids are first separated by allowing them to deposit in special tanks or catch-pits. This deposit is frequently of considerable manurial value, especially when deposited in dry weather, as it contains, in many cases, pieces of fœcal matter, offal, manure washed from roads, and similar substances. Where there is not objection to a manure having an unpleasant smell during its application to the land, this material provides a useful substitute for farm-yard manure. If collected during wet periods it is liable to contain an excessive quantity of sand and grit washed from the roads.

The lighter solids in sewage, forming the largest bulk, are usually separated either by simple deposition in tanks, or by the addition of chemical precipitants such as lime, salts of iron, or alumina. The salts of iron and alumina commonly used as precipitants are sulphates and chlorides of iron, and the sulphate of alumina. Alumino-ferric, which is largely used for the purpose, is a mixture of crude ferric sulphate and alumina.

The sludges formed, when merely dried in the air remain pasty in character for a long period. In some cases the moisture is partially removed by compression in filter presses, usually after the addition of lime, and the sludge is then obtained in the form of "pressed cake" or "sludge cake." This material, when allowed to weather in the air for a few months, has the appearance of a rich loam, and is in a very suitable condition for application to land. It is practically odourless. Apply about 1 ton of it to each 300 sq. yds. of land.

Such manures may be properly applied in the autumn or early spring. Owing to the low potash content of sewage manures it is advisable, where possible, to apply a dressing of a potash salt with manure to land on which potash-loving crops are to be grown. A quantity of a potash salt or flue dust, equivalent to 2–3 lb. of potash per ton of manure would be suitable. Lime should, of course, be present in sufficient quantity, but where lime is used in the precipitation or pressing of the product, there is usually no deficiency of this constituent.

An objection frequently raised to the use of sewage manures is the presence of various seeds derived from kitchen wastes, and washed from gardens, roads, etc., into the sewers. If, however, the manure is allowed to stand in heaps for some time, this difficulty is usually removed by reason of such seeds becoming rotted.

A further and real objection to sewage manures produced particu-

larly in towns where textile industries are common, is the presence of grease or fats. In some cases the grease is recovered, and the resulting sludge is said to be "degreased." It is, however, frequently found that sludges still contain more grease than is present in the products of towns or villages where no such industries exist. If such products are shaken with a little ether or petroleum spirit, and the settled spirit is decanted and allowed to evaporate, a residue of grease will be left behind, if present.

The value of sewage as a true fertiliser, in the restricted sense, is not, however, so great as might be supposed, but it may be usefully employed where it can be placed on the land at a cheap rate or during a scarcity of other manures. A Royal Commission on Sewage Disposal made elaborate investigations on the manurial value of sewage sludges, and found that at that time, viz., in the year 1908, the sludges experimented upon would not have a value exceeding 10s. per ton.

Sewage sludges vary greatly in composition, by reason of variation in the sewage and in the modes of treatment. They are usually somewhat deficient in potash.

The following analysis may be taken as typical of a prepared and dried sludge from a town sewage in which lime has been used as a precipitant:—

	Per cent.
Phosphate of Lime	1·22
Sulphate of Lime	1·45
Carbonate of Lime (variable)	38·86
Carbonate of Magnesia	1·33
Hydrate of Magnesia	1·42
Oxide of Iron	3·55
Alumina	10·64
Silica	13·75
Organic Matter [1]	23·78
Water at 100° C.	4·32

[1] Nitrogen, 0·70 per cent.; equal to Ammonia, 0·85 per cent.

Many patent manures derived from sewage sludges have been placed on the market from time to time, at prices exorbitantly in excess of their manurial values. Such products should only be purchased on analysis, and with a guarantee of their composition.

Sewage manures, in common with other artificial fertilisers, are most usefully and conveniently applied when dried, and in the form of a finely divided powder. It is probable that a slight loss of nitrogen in the form of ammonia occurs in the drying process, but there are corresponding advantages in the matter of transport, application, and storage.

It may be asked what vegetables sewage manures are specially suitable for, so it may be useful to record here that Beet, Cabbage, Carrots, Celery, Kohl Rabi, Leeks, Onions, Parsnips, Potatoes, Salsafy, Tomatoes, and Turnips have been grown with great success on land treated with sewage manures.

At the present time an improved method of dealing with sewage by bacteriological action is being developed, which gives promise of yielding a fertiliser described as "Activated Sludge," much richer in nitrogen and phosphoric acid than ordinary sludges. This process is, however, still in its experimental stage, satisfactory means for preparing and drying this material in bulk not having yet been developed.

A note of warning should be added in respect of the use of so-called manures taken from household ash-pits. Such products have little, if any, manurial value, and the presence of partially burnt coal and ashes renders them distinctly objectionable for application to the soil.

JNO. H.

SHADE: PLANTS AND SHRUBS FOR.—See *SHADY BORDERS*.

SHADE: ROCK PLANTS FOR.—See ROCK PLANTS FOR SHADE in *ROCK PLANTS FOR ALL PURPOSES*.

SHADY BORDERS: PLANTS AND SHRUBS FOR.—Some plants and shrubs will grow and flower better, naturally, in shady places than in those directly exposed to the sun; but many more will thrive in such positions than is usually realised. The worst place to deal with is directly under trees. Dense shade and drip are two opposing factors to be reckoned with here, when considering successful gardening; but still, a good measure of satisfaction can be attained with a little wise forethought.

Thorough preparation of the ground and the careful choice of subjects are the two secrets of success, especially in the case of plants under trees, whose roots soon rob the soil of its food to the detriment of smaller plants and shrubs. Indeed this robbery goes on seriously where borders are shaded by the close proximity of trees, while not necessarily under the trees. In both cases the remedy is the same,—the soil must be liberally enriched to give the subjects a chance of becoming established. Once the plants are "at home," future assistance is best given by mulching or top-dressing. Success under trees will be the better guaranteed if all low branches can be removed from the trunks.

It must not be thought that all plants and shrubs recommended will please in every instance. They will not; experience alone will show which are to be relied upon in any given locality. Cultivation may have been of the highest, and yet plants in identical sites, but in different districts, flourish in one and die or languish in the other. And why? Mostly, we are convinced, because of the variableness of soils. Generally speaking, better results can be expected from light soils in shady situations than from heavy soils similarly placed. In fact plants advised usually for shade should be grown in the open if the soil be of a clayey disposition. One grand exception to this rule is found in Daffodils.

Having already mentioned that other plants will do in shade, or partial shade, besides those popularly associated with these positions, it need only be added that such conscripted subjects will not yield the same quality flowers as those in open positions and, of course, will be later in flowering.

Suitable Subjects for Shade.—A good selection of plants and shrubs suitable for shady places is the following — those followed by an asterisk being the better to use under trees:—

Acanthus.
Aconites (winter).*
Aconitum.
Amelanchier canadensis.
Anemone (in var.).
Aquilegia.
Asperula.
Astilbe.
Azaleas (hardy).
Bamboos.
Berberis Aquifolium.*
Calceolaria.
Campanula (in variety).
Chamaerops.
Clethra.
Colchicum.*
Corydalis.
Crocus.*
Cyclamen (hdy.).*
Cypripedium spectabile.
Daffodils.*
Deutzia.
Dicentra spectabilis.
Digitalis.*
Dipsacus.
Dodecatheon.
Doronicum.
Epimedium.
Eranthis.
Erythronium.
Euphorbia.*
Ferns.*
Fuchsia.
Funkia.
Gaultheria.
Gentiana asclepiadea.
Heliotrope.
Helleborus.
Hemerocallis.
Hepatica.
Holly.*
Hoteia.
Hyacinth (Common Bluebell).
Hydrangea.
Iberis (Perennial Candytuft).
Iris (some of the non-bulbous).
Ivies.*
Juniper.*
Leucojum.*
Liliums (partial shade).
Lily of the Valley.
Lunaria.

Lupine.
Lysimachia.*
Mimulus luteus (shade and damp).
Myosotis.
Œnothera.
Olearia Haastii.
Orchis (shade and damp).
Oxalis.
Paeony.
Papaver.
Petasites.*
Polygonum.*
Primula.
Rhododendrons.
Ribes.
Rudbeckia speciosa.
Ruscus aculeatus.*
Saxifrages (mossy).
Scilla.
Senecio.
Solomon's Seal.*
Spiraea.
Thalictrum.
Trillium.*
Trollius.
Veronicas (shrubby).
Viburnum.
Vinca.*
Viola.—C. T.

[See also the article on *North Borders*.—Editor.]

SHADY LAWNS.—See *Lawns and their Management*.

SHAGGY CAPS.—See Edible Fungi in *Fungi: Edible and Harmful*.

SHALLON (*Gaultheria Shallon*).—See *Shrubs*.

SHALLOT.—See *Medicinal Herbs* and *Shallots*.

SHALLOTS (*Allium ascalonicum*. Nat. Ord. Liliaceæ).—These are certainly one of the best paying crops now largely cultivated by kitchen-gardeners and allotment-holders. Those who do not share this opinion can hardly have given the crop the liberal treatment it certainly deserves.

Culture.—A good rich bed should always be provided, and the earlier this is prepared in the winter, the better it will be. Plant any time from December 21st until the middle of March, in rows 9–12 ins. apart, allowing about 9 ins. between the sets. In planting, make no attempt to bury the bulbs, or "cloves" as they are often called, but simply push them far enough into the soil to prevent strong wind displacing them before they get well rooted. During May and June, use manure water, or one of the advertised manures, freely between the rows, and keep the soil stirred with the hoe.

In ordinary seasons the crop is ready for lifting early in July, the withered tops showing when this stage is reached. After lifting, allow the crop to get thoroughly dry by full exposure to the sun. Store in a dry room for winter use. Bulbs may also be raised from seed sown in the open during March, but the above is the most satisfactory and most generally adopted plan.

Several varieties are found in seed-lists, but *Dobbie's Exhibition* or *Russian Giant* are double the size of the ordinary.—F. R. C.

SHAMROCK (*Trifolium dubium*).—See *Trifolium*.

SHAPE OF BEDS.—See *Beds: Shape and Character of*.

SHASTA DAISY (*Chrysanthemum maximum*).—See *Chrysanthemum: Perennial Border Species*.

SHAVINGS MANURE.—See under Wood Shavings Manure in *Horse Manure*.

SHAWANESE SALAD (*Hydrophyllum virginicum*).—See *Hydrophyllum*.

SHEARS.—See *Garden Tools*.

SHEEP LAUREL (*Kalmia angustifolia*).—See *Shrubs*.

SHEEP MANURE.

Sheep are often put to graze in cricket or football fields, and a large quantity of their manure accumulates, as, of course, the dung has to be swept up before the ground can be played on. Gardeners do not seem to have realised the value of this manure, or the heaps of it which one sees as above mentioned would be quickly disposed of.

Sheep dung is a hot fermenting sulphurous solid, not highly charged with water as are cow and pig manure. It is very suitable for digging into clay soils after it has decomposed in a protected heap for about a month, and may be used at the rate of 2–4 cwt. per sq. rod, according to the richness of the land.

Goat Manure.—This is coming to the front a good deal on account of the increase of goat-keeping. It resembles sheep manure in its general properties, and may be used in the same manner.—E.

SHEEP POISON (*Lupinus densiflorus*). See *LUPINE*.

SHEEP SORREL (*Rumex Acetosella*). See *RUMEX*.

SHEEP'S-BIT SCABIOUS.—A name applied to the genus *JASIONE*, which see.

SHEEP'S FESCUE (*Festuca ovina*).—See *FESTUCA*.

SHEEP'S SCABIOUS.—A name applied to the genus *JASIONE*, which see.

SHELL-BARK HICKORY (*Carya alba*). See *TREES*.

SHELLS.—See *FISH AS MANURE*.

SHELTERS.

These are very necessary if the garden is extensive, as April showers, though soon over, are very wetting. Shelters may either take the form of ARBOURS (see article on *ARBOURS AND ARCHES*) or SUMMER-HOUSES (see article on *GARDEN SUMMER-HOUSE*). In either case the roof should be sufficiently well made to ensure complete protection from the heaviest rain. A garden seat or two might well be kept in such shelters so that one can rest from one's labours till the rain ceases.

SHEPHERD'S NEEDLE. — See *SCANDIX*.

SHEPHERD'S PURSE.—See *CAPSELLA* and *WEEDS*.

SHEPHERD'S ROD (*Dipsacus pilosus*).—See *DIPSACUS*.

SHEPHERDIA.—For the best species see *SHRUBS*.

SHERARDIA.—See *FIELD MADDER*.

SHINGLE OAK (*Quercus imbricaria*). See *TREES*.

SHINING PINK (*Dianthus nitidus*).—See *DIANTHUS*.

SHINING WILLOW (*Salix lucida*).—See *TREES*.

SHIRLEY POPPIES.—See *POPPIES: ANNUAL SPECIES*.

SHODDY AS MANURE. — See "Waste Hair" in our notes on ORGANIC PRODUCTS under NITROGENOUS MANURES in *MANURES*.

SHOE-STRINGS (*Amorpha canescens*). See *SHRUBS*.

SHOOT AND FRUIT CURRANT MOTH.—See *INSECT PESTS*.

SHOOTING STARS.—A name applied to the genus *DODECATHEON*.

SHORE-WEED.—See *LITTORELLA*.

SHORT-STEMMED FLOWERS.—See *FLOWERS UNSUITABLE FOR CUTTING*.

SHORTHORN CARROTS. — See *CARROT*.

SHORTIA (CRIMSON LEAF. Nat. Ord. Diapensiaceæ).—This is a somewhat remarkable genus of only two species, one of which is found in North America and the other in Japan. Both are shade-loving plants, and require a cool, moist, but well-drained position in sandy loam and peat. They are propagated by careful division in spring.

S. galacifolia.—This bears tufts of glossy leaves which are tinted crimson in the autumn. Flowers white, changing to rose with age. Flowering Period, May to June. Height, 6 ins.

S. uniflora.—This has smaller leaves in tufts. Flowers pale rose. Flowering Period, May to June. Height, 4 ins. The variety *grandiflora* bears larger flowers, which are deeper in colour.

SHOVELS.—See *GARDEN TOOLS*.

SHOW AURICULAS.—See *AURICULA*.

SHOW DAHLIAS. — See *DAHLIA: CULTURE OF*.

SHOWY LILY TREE (*Magnolia conspicua*).—See *CLIMBING AND TRAILING PLANTS*.

SHRIMP REFUSE.—See *FISH AS MANURE*.

SHRUB BANKS.—See *BANKS.*

SHRUB BORDERS: TOP-DRESSING FOR.—See *TOP-DRESSING.*

SHRUBBERIES: HERBACEOUS PLANTS FOR.—Any of the coarser-growing and stronger hardy perennials are eminently suitable for the borders which so often form the margins to shrubberies, provided these borders get a reasonable amount of sun. It is needless to give a list of suitable subjects here, since even the veriest amateur will be able to think of plenty of suitable subjects without the least difficulty. In the articles on the plants themselves care has been taken to mention a few of these species instead of omitting them entirely, and usually the reader's attention is specially drawn to the fact that the species is more suitable for the shrub border than for the perennial parterre.

SHRUBBERIES: MANAGEMENT OF. A well-arranged and carefully tended Shrubbery is one of the finest features of a well-managed garden, but unfortunately this is but seldom met with. Bad selections of kinds, much too close planting, and the introduction of tall-growing trees are in most cases the main causes of failure.

In laying out a shrubbery it is essential that the habits of the various plants be fully understood, and then a proper arrangement can be planned and carefully carried out. It must never be forgotten that it is but a few kinds of shrubs that can be got to thrive under trees, so the site chosen must be open and sunny for the great bulk of ornamental bushes, whether grown for their flowers or foliage.

When first laying out a shrubbery the tendency is to plant much too closely together, for the sake of immediate effect, and although most of us have this weakness, it cannot be too strongly condemned, unless arrangements are made to thin out rigorously before over-crowding has spoiled the symmetry of the different plants. One is not always able, because of the want of space, to plant each species by itself, but where at all possible this method is to be commended, as it not only makes it much easier to provide suitable soil for each, but the subsequent treatment is much simplified, and in most cases the effect is very pleasing. Even in quite a small shrubbery, clumps of half a dozen or so of each kind chosen, will give better results than an indiscriminate mixture of a large number of species. If carefully done, the planting or transplanting of shrubs may be successfully carried out from September to May, but October and November, and February and March for the general run of shrubs, may be said to be the most favourable times, with April or early May for hybrid rhododendrons and hollies. When planted in late spring, and a dry summer follows, copious watering will be a necessity.

In preparing the ground for shrubs of all kinds, it is advisable first to trench or double-dig it, working in some vegetable mould, or such like, if the soil is at all poor.

In the case of Azaleas, Heaths, Kalmias, Rhododendrons, and other peat-loving subjects, where procurable, a large amount of fibrous peat should be added to the soil, but all the same, grand results are had on moist, clayey loams with these plants, without such admixture. Care must always be taken to exclude lime in any form from the soil in which these peat-lovers are planted.

After a time it not infrequently

happens that shrubs of various kinds begin to show signs of exhaustion. Many people believe that such plants cannot be brought back to health and vigour, and yet this is easily accomplished by a generous application of well-rotted farmyard manure. This may be applied merely as a mulch, or lightly forked into the surface, taking care not to damage the roots. Even where no manuring is necessary, the surface of the ground should be lightly forked over every winter, and during the summer frequently hoed, not only for the sake of tidiness but also as an aid to the plants.

The question of pruning is one of the great stumbling-blocks in connection with the culture of shrubs to many gardeners, and not infrequently all are allowed to grow as they choose, and so very often get out of shape and become an eyesore.

All the commoner kinds that are grown for their foliage alone may, speaking generally, be pruned during the winter months, but flowering kinds should usually be treated just after the flowers fade. In the case of the latter, of course, few of them really require pruning in the accepted sense of the word, but the shortening back of a straggly growth here and there is often a decided benefit. In the case of Deutzias, Lilacs, and others of this nature, some of the old wood should be cut clean out, so as to encourage the growth of strong young shoots for future blooming. (See *Pruning Roses and Shrubs.*)

The removal of all faded flowers and seed-pods from Azaleas, Rhododendrons, etc., is a distinct benefit to the plants, besides adding materially to the appearance of the shrubbery. Remove annually all dead branches and all suckers from grafted bushes.—C. B.

SHRUBBY CLIMBERS.—See *Climbing and Trailing Plants.*

SHRUBBY WISTARIA (*Wistaria frutescens*). — See *Climbing and Trailing Plants.*

SHRUBS.

It is obviously impossible to describe the thousands of species and varieties of shrubs now available to the gardener. The limited space at our command will prevent this, and, except for giving short articles on *Evergreens*, *Flowering Shrubs*, *Rhododendrons*, and a few others, we are contenting ourselves with giving the list below, which comprises all the best shrubs for the garden of the amateur. Unless definitely stated to the contrary, all the shrubs are hardy in the average climate of the British Isles. Evergreen species are marked *E.*, and those which are tender or half-hardy are marked *H.H.E.*, in the case of the evergreen, and *H.H.D.* for the tender or half-hardy deciduous kinds. Species not marked with any initials are deciduous. For full descriptions and further cultural details the reader must consult larger works, and he should read nurserymen's catalogues for the numerous varieties in commerce. It may be said, however, that those named will generally thrive in ordinary garden soil, lightened if heavy by the addition of some leaf-soil. The names given are those recognised at Kew, and synonyms are in most cases omitted, as they are in many instances very confused and too numerous. Climbers are not included in the list below, but they will be found dealt with in our article on *Climbing and Trailing Plants.* Subjects specially suitable for use as Foliage Plants will be found in our article on *Foliage Plants for All Purposes.*—Editor.

Select List of Garden Shrubs.

ABELIA.

A. chinensis.—The Rock Abelia, with pink flowers in August and September. Height, 2–3 ft.

A. floribunda (*E.*). — Rosy purple flowers in March. Height, 3 ft.

A. spathulata (*H.H.E.*). — Pink flowers in April. Height, 2–3 ft.

A. triflora (*H.H.E.*).—Yellow and pink flowers in September. Height, 6 ft.

ABUTILON. See also separate article and article on *Climbing and Trailing Plants.*

A. vitifolium. — Lilac flowers in June. Height, 10 ft.

ADENOCARPUS.

A. decorticans (*H.H.E.*).—Yellow flowers in May. Height, 3 ft.

ÆGLE. Bengal Quince or Hardy Orange.

Æ. sepiaria (*E.*).—White flowers in April. Height, 4–10 ft.

AMELANCHIER. June Berry.

A. alnifolia.—The Dwarf June Berry, with white flowers in April. Height, 8 ft.

A. canadensis.—The June Berry or Service-berry, with white flowers in April. Height, 8–10 ft.

A. vulgaris.—The Common Amelanchier, with white flowers in April. Height, 8–16 ft.

AMORPHA. Lead Plant.

A. canescens.—The Lead Plant and Shoe-strings, with dull-blue flowers in July. Height, 3 ft.

A. fruticosa in variety.—The False Indigo, with purple flowers in June. Height, 6 ft.

ANDROMEDA.

A. polifolia (*E.*). — The Wild Rosemary, with pinkish-white flowers in June. Height, 1 ft.

ARALIA.

A. cachemirica.—White flowers in July. Height, 6–10 ft.

A. chinensis. — White flowers in August. Height, 10 ft.

A. spinosa.—The Angelica Tree and Hercules' Club, with white flowers in August. Height, 3–10 ft.

ARBUTUS. Strawberry Tree.

A. Andrachne (*E.*).—Greenish-white flowers in March and April. Height, 8–10 ft.

A. hybrida (*H.H.E.*). — White flowers from September onwards. Height, 8–10 ft.

A. Menziesii (*E.*).—The Madroño with white flowers in September Height, 10 ft.

A. Unedo in variety (*H.H.E.*).—The Strawberry Tree, with white to red flowers in September. Height, 6–10 ft.

ARCTOSTAPHYLOS. Bearberry.

A. alpina (*E.*).—The Black Bearberry, with white or pink flowers in April. Height, 1 ft.

A. tomentosa (*E.*).—The Manzanita, with white flowers in November. Height, 4 ft.

A. Uva-ursi (*E.*).—The Bearberry, with white flowers in April. Trailer.

ARTEMISIA. Mugwort, Southernwood, and Wormwood. See also separate article.

A. Abrotanum (*E.*). — The well-known Southernwood, with yellowish flowers from August to October. Height, 1–4 ft. (See also Southernwood in article on *Medicinal Herbs.*)

A. Absinthium (*E.*). — The well-known Wormwood, with yellow flowers. Height, 1–2 ft. (See also Wormwood in article on *Medicinal Herbs.*)

A. coerulescens (*E.*).—Yellow flowers in August. Height, 2 ft.

A. procera (*E.*).—The Sage-bush, with yellow flowers in August. Height, 1–2 ft.

A. tridentata (*E.*).—Yellow flowers in August. Height, 1–10 ft.

ASTRAGALUS. Milk Vetch. See also separate article.

A. Tragacantha (*E.*).—The Gum Tragacanth, with violet flowers in June. Height, 1–3 ft.

AUCUBA.

A. japonica in variety. (*E.*).—A foliage plant. Height, 4–10 ft.

AZALEA. See separate article.

AZARA.

A. Gilliesii (*E.*).—Yellow flowers in May. Height, 10 ft.

A. microphylla (*E.*). — Greenish flowers in August. Height, 6–12 ft.

BERBERIDOPSIS. See article on *Climbing and Trailing Plants.*

BERBERIS. Barberry.

B. Aquifolium, Syn. *Mahonia Aquifolium* (*E.*).—The Mahonia, with yellow flowers in March. Height, 2–6 ft.

B. aristata.—Yellow flowers in April. Height, 6 ft.

B. buxifolia (*E.*).—Yellow flowers from March to April. Height, 8 ft.

B. buxifolia nana (*E.*). — Yellow flowers in March. Height, 1½ ft.
B. canadensis.—The AMERICAN BARBERRY, with yellow flowers from May onwards. Height, 6 ft.
B. Darwinii (*E.*).—Yellow flowers in May. Height, 8 ft.
B. dictyophylla.—Yellow flowers from May onwards. Height, 1–2 ft.
B. empetrifolia (*E.*).—Yellow flowers in May. Height, 1–2 ft.
B. Gagnepainii (*E.*).—Yellow flowers in May. Height, 3–6 ft.
B. japonica (*E.*).—Yellow flowers in May. Height, 6 ft.
B. Knightii (*E.*).—Yellow flowers in May. Height, 3–6 ft.
B. laevis.—Yellow flowers in May. Height, 3–4 ft.
B. pinnata.—Yellow flowers in May. Height, 3–10 ft.
B. pruinosa.—Yellow flowers from April onwards. Height, 3–6 ft.
B. sargentiana (*E.*).—Yellow flowers from May onwards. Height, 3–6 ft.
B. stenophylla in variety (*E.*).—Yellow flowers in May. Height, 3–8 ft.
B. Thunbergii.—Yellow flowers from April onwards. Height, 2–6 ft.
B. vulgaris in variety.—The BARBERRY or COMMON BARBERRY, with yellow flowers in April. Height, 3–20 ft.
B. wallichiana (*E.*).—Yellow flowers in April. Height, 6–10 ft.
B. Wilsoni.—Yellow flowers in May. Height, 2–4 ft.

BRYANTHUS.
B. erectus (*E.*).—Purple flowers in April. Height, 1 ft.

BUDDLEIA. See also article on *CLIMBING AND TRAILING PLANTS*.
B. albiflora.—White flowers in July. Height, 6–8 ft.
B. Colvillei (*H.H.E.*).—Deep rose flowers in July. Height, 10–20 ft.
B. globosa (*H.H.E.*).—The ORANGE BALL TREE, with orange flowers in July. Height, 6–12 ft.
B. variabilis in variety, with purple or lilac flowers in July. Height, 8–15 ft.

BUPLEURUM. HARE'S EAR.
B. fruticosum (*E.*).—Yellow flowers in August. Height, 1–2 ft.

BUXUS. Box.
B. balearica (*E.*).—The MINORCA BOX. A foliage plant. Height, 6–8 ft.
B. Fortunei (*E.*).—A foliage plant. Height, 4–8 ft.
B. sempervirens in variety (*E.*).—The SILVER BOX. A foliage plant. Height, 1–20 ft.
B. sempervirens suffruticosa (*E.*).—This is the form used for edgings, and popularly known as EDGING BOX.

CAESALPINIA. BRASILLETO.
C. sepiaria.—Yellow flowers in May. Height, 6 ft.

CALLUNA. HEATH, HEATHER, or LING. See also article on *HEATHS*.
C. vulgaris in variety (*E.*).—The COMMON HEATHER or LING, with purple to white flowers in August. Height, 1 ft.

CALYCANTHUS. ALLSPICE.
C. floridus.—The CAROLINA ALLSPICE, with purple flowers in May. Height, 4 ft.
C. occidentalis.—The CALIFORNIAN or WESTERN ALLSPICE, with red flowers from June onwards. Height, 6–8 ft.

CAMELLIA. See also separate article.
C. japonica in variety (*H.H.E.*).—White to crimson flowers from March onwards. Height, 6–15 ft.

CARAGANA. PEA TREE.
C. arborescens.—The SIBERIAN PEA TREE, with yellow flowers from April onwards. Height, 8–10 ft.

CARPENTARIA.
C. californica (*H.H.E.*). — White flowers from May onwards. Height, 6–10 ft.

CASSANDRA.
C. calyculata (*E.*).—The LEATHERLEAF, with white flowers in May. Height, 2 ft.

CASSINIA.
C. fulvida, with white flowers in July. Height, 4 ft.

CEANOTHUS. See also article on *CLIMBING AND TRAILING PLANTS*.
C. americanus (*E.*). — The NEW JERSEY TEA, with white flowers from June onwards. Height, 2–8 ft.
C. azureus in variety (*H.H.E.*).—Blue flowers from June onwards. Height, 5–10 ft.
C. dentatus (*H.H.E.*).—Blue flowers from May onwards. Height, 6 ft.
C. divaricatus (*H.H.E.*). — Blue flowers from May onwards. Height, 6 ft.
C. thyrsiflorus (*H.H.E.*). — The CALIFORNIA LILAC, with blue flowers in May. Height, 8–10 ft.
C. veitchianus (*H.H.E.*). — Blue flowers from May onwards. Height, 6–8 ft.

CHIMONANTHUS. WINTER SWEET.
C. fragrans.—White and purple

flowers from November onwards. Height, 6 ft.

CHIONANTHUS. FRINGE TREE.

C. virginica.—White flowers in May. Height, 6–15 ft.

CHOISYA. MEXICAN ORANGE FLOWER.

C. ternata (*E.*).—White flowers from May onwards. Height, 6–10 ft.

CISTUS. ROCK ROSE. See also article on *CLIMBING AND TRAILING PLANTS.*

C. crispus (*H.H.E.*).—Purple flowers in June. Height, 2 ft.

C. cyprius (*H.H.E.*).—White flowers in June. Height, 4 ft.

C. florentinus (*H.H.E.*). — White flowers in June. Height, 4 ft.

C. ladaniferus (*H.H.E.*).—The GUM CISTUS, with white flowers in June. Height, 4–6 ft.

C. laurifolius (*E.*).—White flowers in June. Height, 4–6 ft.

C. lusitanicus (*H.H.E.*). — White flowers in July. Height, 2–4 ft.

C. monspeliensis (*H.H.E.*).—White flowers in July. Height, 2 ft.

C. purpureus (*H.H.E.*). — Purple flowers from June onwards. Height, 2 ft.

C. salvifolius in variety (*H.H.E.*).—White flowers from June onwards. Height, 2 ft.

C. villosus (*H.H.E.*).—Purple flowers in June. Height, 3 ft.

CLERODENDRON.

C. trichotomum.—White and purple flowers in September. Height, 8 ft.

CLETHRA. PEPPER TREE.

C. acuminata.—The WHITE ALDER, with white flowers in July. Height, 5–8 ft.

C. alnifolia.—The PEPPER TREE or SWEET PEPPERBUSH, with white flowers in July. Height, 5 ft.

C. canescens (*H.H.E.*).—White flowers in July. Height, 5–6 ft.

COLLETIA.

C. cruciata.—The ANCHOR PLANT, with white flowers from June onwards. Height, 4 ft.

C. spinosa.—White flowers in June. Height, 6–12 ft.

COLUTEA. BLADDER SENNA.

C. arborescens.—Yellow flowers in May. Height, 10 ft.

C. cruenta.—Copper-red flowers in June. Height, 6–8 ft.

C. japonica.—Red flowers in May. Height, 2–4 ft.

CORNUS. DOGWOOD.

C. alba in variety.—White flowers in May. Height, 6–8 ft.

C. Amomum.—The KINNIKINNIK, with yellow-white flowers in June. Height, 8 ft.

C. capitata (*H.H.E.*).—Green and yellow flowers in June. Height, 6–8 ft.

C. florida (*H.H.E.*).—The FLOWERING DOGWOOD, with white flowers in April. Height, 8–15 ft.

C. Kousa.—Yellow and white flowers in June. Height, 6–8 ft.

C. macrophylla.—White flowers in July. Height, 10–15 ft.

C. Mas in variety.—The CORNEL or CORNELIAN CHERRY, with yellowish flowers in February. Height, 8–10 ft.

C. Nuttallii.—White flowers in June. Height, 6–8 ft.

C. sanguinea.—The COMMON DOGWOOD or DOGBERRY, with green and white flowers in June. Height, 6–10 ft.

C. stolonifera. — The RED-OSIER DOGWOOD, with whitish flowers in May. Height, 6 ft.

C. tartarica in variety. — White flowers in July. Height, 8 ft.

COROKEA.

C. Cotoneaster (*H.H.E.*).—Yellow flowers in June. Height, 6 ft.

CORONILLA. SCORPION SENNA. See also separate article.

C. Emerus.—Yellow flowers in April. Height, 3–4 ft.

CORYLOPSIS.

C. himalayana.—Yellow flowers in March. Height, 6 ft.

C. pauciflora.—Yellow flowers in March. Height, 6 ft.

C. spicata.—Yellow flowers in February. Height, 3–4 ft.

CORYLUS. See article on *TREES.*

COTONEASTER. ROCK SPRAY.

C. acuminata.—White flowers in May. Height, 3–6 ft.

C. acutifolia.—White flowers in May. Height, 4–6 ft.

C. adpressa.—White flowers in April. Height, 1 ft.

C. affinis.—White flowers in May. Height, 3–6 ft.

C. bacillaris.—White flowers in May. Height, 4–8 ft.

C. buxifolia (*E.*).—Pink flowers in April. Height, 6–10 ft.

C. Franchetii (*E.*).—White flowers in May. Height, 6–8 ft.

C. frigida.—White flowers from April onwards. Height, 8–15 ft.

C. horizontalis (*E.*).—Pinkish flowers from April onwards. Height, 2–4 ft.

C. humifusa (*E.*).—White flowers from April onwards. Height, 1 ft.
C. microphylla (*E.*).—White flowers from April onwards. Height, 4–8 ft.
C. pannosa.—Yellowish-white flowers in May. Height, 2–6 ft.
C. reflexa.—White flowers from May onwards. Height, 2–6 ft.
C. rotundifolia (*E.*).—White flowers from April onwards. Height, 3–6 ft.
C. rugosa Henryi.—White flowers from May onwards. Height, 6 ft.
C. salicifolia (*E.*).—White flowers in May. Height, 6 ft.
C. Simonsii.—White flowers in May. Height, 6 ft.
C. turbinata (*E.*).—White flowers in May. Height, 6–8 ft.
C. uniflora (*E.*).—White flowers in May. Height, 6–8 ft.

CYDONIA. QUINCE. See also PYRUS in article on *TREES*, and article on *QUINCES*.
C. japonica in variety.—The JAPAN QUINCE or JAPANESE QUINCE, with crimson to white flowers in April. Height, 6–8 ft.
C. Maulei in variety.—Scarlet to white flowers in March. Height, 3–4 ft.
C. sinensis (*H.H.D.*).—The CHINESE QUINCE, with flowers of various colours in the spring. Height, 10–20 ft.
C. vulgaris. See article on *QUINCES*.

CYTISUS. BROOM.
C. albus.—The WHITE SPANISH BROOM, with white flowers in May. Height, 4–8 ft.
C. Ardoini.—Yellow flowers from May onwards. Height, ½–1 ft.
C. austriacus.—Yellow flowers in June. Height, 3–5 ft.
C. Beanii.—Yellow flowers in May. Height, 2–4 ft.
C. biflorus.—Yellow flowers in May. Height, 2–4 ft.
C. capitatus.—Yellow flowers in July. Height, 3–6 ft.
C. Dallimorei.—Pink flowers in June. Height, 3 ft.
C. decumbens.—Pink flowers in June. Height, 2–3 ft.
C. kewensis.—Creamy-yellow flowers in May. Height, 1–2 ft.
C. nigricans Carlieri.—Yellow flowers in July. Height, 3–5 ft.
C. praecox.—Cream or white flowers in April. Height, 4–6 ft.
C. purpureus in variety.—Red, pink, or white flowers in June. Height, 2–3 ft.
C. schipkaensis.—White flowers in May. Height, 1 ft.
C. scoparius in variety.—The COMMON BROOM, with yellow flowers in May. Height, 4–8 ft.
C. scoparius andreanus.—Yellow and brown flowers in May. Height, 4–8 ft.

DABOËCIA. ST. DABEOC'S HEATH. See also article on *HEATHS*.
D. polifolia in variety.—Purple to white flowers in May. Height, 1 ft.

DAPHNE. See also separate article.
D. blagayana (*E.*).—The KING'S GARLAND FLOWER, with white flowers in May. Height, 1 ft.
D. Cneorum.—The GARLAND FLOWER, with red flowers in June. Height, 1–2 ft.
D. Laureola.—The SPURGE or WOOD LAUREL, with yellowish flowers in April. Height, 1–3 ft.
D. Mezereum in variety.—The MEZEREON, with purple to white flowers from February onwards. Height, 3–5 ft.
D. pontica (*E.*).—Greenish flowers from April to May. Height, 2–3 ft.

DAPHNIPHYLLUM.
D. macropodum (*E.*).—The SIOUMI, with black fruit in autumn and insignificant flowers. Height, 6 ft.

DESFONTAINEA.
D. spinosa (*E.*).—Scarlet and yellow flowers in August. Height, 3–6 ft.

DEUTZIA.
D. corymbosa.—White flowers in May and June. Height, 8 ft.
D. crenata in variety.—White or pink flowers in June. Height, 4–8 ft.
D. discolor in variety.—White to pink flowers in May. Height, 2–3 ft.
D. gracilis in variety.—White flowers in May. Height, 2–3 ft.
D. Lemoinei in variety.—White to pink flowers in May. Height, 3–5 ft.
D. parviflora.—White flowers in May. Height, 2–3 ft.
D. scabra.—White flowers in May. Height, 2–3 ft.
D. Vilmoriana.—White flowers in June. Height, 4–8 ft.
D. Wilsonii.—White flowers in June. Height, 2–4 ft.

DIERVILLA (Syn. *Weigela*). BUSH HONEYSUCKLE.
D. florida in variety.—White to red flowers in April. Height, 4–6 ft.
D. hortensis in variety.—White to

red flowers in April. Height, 4–5 ft.
D. japonica.—Red flowers from April onwards. Height, 4–6 ft.
D. Lonicera.—Yellow flowers in May. Height, 3 ft.
D. middendorfiana.—Yellowish-white flowers in May. Height, 3 ft.
D. sessilifolia.—Yellow flowers in May. Height, 3–6 ft.

ELAEAGNUS.
E. angustifolia.—Yellowish flowers in August. Height, 6 ft.
E. argentea.—The SILVER BERRY, with yellow flowers from July onwards. Height, 6 ft.
E. glabra.—The YAMA GUMI, with white flowers in August. Height, 3–6 ft.
E. macrophylla (*E.*). — The FON GUMI, with yellowish flowers in August. Height, 6 ft.
E. pungens (*E.*).—The NATSU GUMI, with yellowish flowers in August. Height, 6 ft.
E. umbellata.—The MASIRO GUMI, with white flowers in June. Height, 6 ft.

EMBOTHRIUM. FIRE BUSH.
E. coccineum (*H.H.E.*). —Scarlet flowers in May. Height, 3 ft.

ENKIANTHUS.
E. campanulatus (*H.H.E.*).—Red flowers in May. Height, 5–10 ft.
E. himalaicus (*H.H.E.*).—Orange-red flowers in June. Height, 8–15 ft.
E. japonicus (*H.H.E.*). — White flowers in March. Height, 4–10 ft.

ERICA. HEATH. See also article on *HEATHS.*
E. arborea (*H.H.E.*).—The TREE HEATH, with white flowers in May. Height, 5 ft.
E. australis (*H.H.E.*). — Purple flowers in March. Height, 2–3 ft.
E. carnea (*E.*).—Purple to white flowers from January onwards. Height, 1 ft.
E. lusitanica (*H.H.E.*). — Purple flowers in May. Height, 3–5 ft.
E. mediterranea in variety (*E.*).—Purple to white flowers in February. Height, 1 ft.
E. stricta (*E.*).—Purple flowers in April. Height, 1 ft.
E. Tetralix in variety (*E.*).—The CROSS-LEAVED HEATH, with purple to white flowers in July. Height, 1 ft.
E. vagans in variety (*E.*).—The CORNISH HEATH, with purple to white flowers in September Height, 2 ft.
E. Veitchii.—Purple flowers in June. Height, 2–3 ft.

ESCALLONIA.
E. exoniensis (*H.H.E.*).—Red flowers in July. Height, 4–6 ft.
E. floribunda (*H.H.E.*) — White flowers in July. Height, 4–6 ft.
E. langleyensis (*E.*).—Red flowers in June. Height, 6–8 ft.
E. macrantha (*H.H.E.*).—Red flowers from June onwards. Height, 3–8 ft.
E. philippiana (*E.*).—White flowers from June onwards. Height, 6 ft.
E. rubra (*H.H.E.*).—Red flowers in September. Height, 3–6 ft.

EUCRYPHIA. See article on *CLIMBING AND TRAILING PLANTS.*

EUONYMUS. SPINDLE TREE. See also article on *CLIMBING AND TRAILING PLANTS.*
E. americanus.—The STRAWBERRY BUSH, with pink flowers from June onwards. Height, 6 ft.
E. atropurpureus.—The BURNING BUSH, with purple flowers in June. Height, 6 ft.
E. europaeus.—The SPINDLE TREE, with white flowers in June. Height, 5 ft.
E. japonicus (*E.*).—Pink flowers in July. Height, 6 ft.
E. radicans. White flowers in July, decumbent.

EXOCHORDA.
E. grandiflora.—White flowers in May. Height, 6 ft.

FABIANA. PICHI.
F. imbricata (*E.*).—White flowers from May onwards. Height, 6 ft.

FATSIA.
F. japonica, Syn. *Aralia Sieboldii* (*H.H.E.*).—White flowers in May. Height, 4–10 ft.

FENDLERA.
F. rupicola (*H.H.E.*).—White flowers in June. Height, 4 ft.

FORSYTHIA. See article on *CLIMBING AND TRAILING PLANTS.*

FOTHERGILLA.
F. Gardeni (Syn. *F. alnifolia*).—White flowers from May to June. Height, 4 ft.

FREMONTIA.
F. californica (*E.*).—Yellow flowers in April. Height, 6 ft.

FUCHSIA. See also separate article.
F. corallina.—Scarlet flowers in July. Height, 4–6 ft.
F. macrostemma.—Scarlet flowers in July. Height, 2–8 ft.

F. procumbens.—Scarlet flowers in June. Height, 1 ft.
F. Riccartoni.—Scarlet flowers in July. Height, 3–8 ft.

GARRYA.
G. elliptica (*E.*).—Greenish flowers in October. Height, 6 ft.

GAULTHERIA. WINTERGREEN. See also separate article.
G. nummularioides (*E.*). — White flowers in May. Height, 6 ins.
G. procumbens (*E.*).—The CREEPING WINTERGREEN or PARTRIDGE BERRY, with white flowers from May to July. Height, 6 ins.
G. Shallon.—The SALAL or SHALLON, with white flowers in May. Height, 2–6 ft.

GENISTA. FURZE.
G. aethnensis (*E.*).—The MOUNT ETNA BROOM, with yellow flowers in July. Height, 4–6 ft.
G. anglica (*E.*). — The NEEDLE FURZE or PETTY WHIN, with yellow flowers in May. Height, 1–2 ft.
G. germanica.—Yellow flowers in July. Height, 3 ft.
G. hispanica (*E.*).—The SPANISH GORSE, with yellow flowers in July. Height, 3 ft.
G. monosperma (*H.H.E.*).—Yellow flowers in June. Height, 3 ft.
G. radiata (*E.*).—Yellow flowers in July. Height, 1½ ft.
G. tinctoria.—The DYERS' GREENWEED, with yellow flowers in July. Height, 6 ft.
G. virgata.—Yellow flowers in July. Height, 5 ft.

HALESIA. SNOWDROP TREE.
H. hispida.—The ASAGARA, with white flowers in May. Height, 6–8 ft.
H. tetraptera.—The SILVER-BELL or SNOWDROP TREE, with white flowers in May. Height, 6–10 ft.

HALIMODENDRON. SALT TREE.
H. argenteum.—Pink flowers in May. Height, 6 ft.

HAMAMELIS. WITCH HAZEL.
H. arborea.—The MANSAK or WITCH HAZEL, with yellow flowers from December onwards. Height, 6–20 ft.
H. japonica.—Yellow flowers from December onwards. Height, 6–15 ft.
H. japonica zuccariniana.—A better form.
H. mollis.—Yellow flowers from December onwards. Height, 10 ft.
H. virginica.—The WITCH HAZEL, with yellow flowers in May.

HEDYSARUM. FRENCH HONEYSUCKLE. See also separate article.
H. multijugum.—Red flowers in July. Height, 4–6 ft.

HELIANTHEMUM. SUN ROSE. See also separate article.
H. formosum (*H.H.E.*). — Yellow flowers in June. Height, 4 ft.
H. halimifolium (*H.H.E.*).—Yellow flowers in June. Height, 4 ft.
H. rosmarinifolium (*E.*).—Yellow flowers in June. Height, 2 ft.
H. vulgare in variety (*E.*).—The ROCK ROSE, with flowers from white to deep red, etc., in June. Height, 9 ins.

HIBISCUS.
H. syriacus in variety (*H.H.D.*).—Red to white flowers in August. Height, 8 ft.

HIPPOPHAE. SEA BUCKTHORN.
H. rhamnoides. — Foliage plant. Height, 2–12 ft.

HYDRANGEA. See also separate article.
H. altissima (*H.H.E.*). — White flowers in August. Height, 6 ft.
H. arborescens (*H.H.E.*). — White flowers in July. Height, 6 ft.
H. hortensis in variety (*H.H.E.*).—White to pink flowers in July. Height, 2–5 ft. Its variety *rosea* has rosy flowers, while its variety *stellata* has pinkish flowers.
H. paniculata.—White flowers from May onwards. Height, 3–6 ft.
H. quercifolia.—White flowers in September. Height, 4 ft.

HYMENANTHERA.
H. crassifolia (*H.H.E.*). — White berries from July onwards. Height, 2–4 ft.

HYPERICUM. ST. JOHN'S WORT. See also separate article.
H. Androsaemum. — The TUTSAN, with yellow flowers in August. Height, 2 ft.
H. Ascyron.—Yellow flowers in June. Height, 2 ft.
H. aureum.—Yellow flowers in June. Height, 2–4 ft.
H. calycinum (*E.*).—The ROSE OF SHARON or TUTSAN, with yellow flowers in July. Height, 1–2 ft.
H. chinense (*H.H.E.*). — Yellow flowers in June. Height, 3 ft.
H. Coris (*H.H.E.*).—Yellow flowers in June. Height, 9 ins.
H. densiflorum.—Yellow flowers in June. Height, 2 ft.
H. elatum—Yellow flowers in July. Height, 5 ft.

H. hircinum.—Yellow flowers in August. Height, 3 ft.
H. hookerianum (*H.H.E.*).—Yellow flowers in July. Height, 2–3 ft.
H. moserianum.—Yellow flowers in July. Height, 3 ft.
H. patulum (*E.*).—Yellow flowers in June. Height, 2 ft.
H. uralum.—Yellow flowers in July. Height, 2 ft.

ILEX. See article on *HOLLY.*

ITEA.
I. virginica.—White flowers in July. Height, 6 ft.

JAMESIA.
J. americana.—White flowers in May. Height, 3–4 ft.

KALMIA.
K. angustifolia in variety (*E.*).—The SHEEP LAUREL, with purple to white flowers in June. Height, 3 ft.
K. glauca.—Purple flowers from April onwards. Height, 2 ft.
K. latifolia (*E.*). — The CALICO-BUSH, with red flowers in June. Height, 8 ft.

KERRIA. JEW'S MALLOW.
K. japonica in variety.—Yellow flowers from March onwards. Height, 5–10 ft.

LAURUS. SWEET BAY.
L. nobilis.—Yellowish-white flowers in April. Height, 6–15 ft.

LAVANDULA. LAVENDER. See also separate article.
L. Spica in variety.—Lilac to white flowers in August. Height, 2 ft.
L. vera.—Blue flowers in July. Height, 2 ft.

LEDUM. LABRADOR TEA.
L. glandulosum (*E.*).—White flowers in April. Height, 2–6 ft.
L. latifolium (*E.*).—The LABRADOR TEA, with white flowers in April. Height, 3 ft.
L. palustre.—White flowers in April. Height, 2 ft.

LEIOPHYLLUM. SAND MYRTLE.
L. buxifolium (*E.*).—White flowers in May. Height, ½–1 ft.

LESPEDEZA.
L. bicolor.—Rose-purple flowers in October. Height, 3 ft.
L. capitata.—The ROUND-HEADED BUSH CLOVER, with purplish flowers in the autumn. Height, 2–3 ft.
L. violacea.—The BUSH CLOVER, with purplish flowers in the autumn. Height, 2–3 ft.

LEUCOTHOE.
L. axillaris (*E.*).—White flowers in May. Height, 1–2 ft.
L. Catesbaei (*E.*).—White flowers in May. Height, 2–4 ft.
L. Davisiae. (*E.*).—White flowers in May. Height, 3–5 ft.
L. racemosa (*E.*).—White flowers in May. Height, 4–10 ft.
L. recurva.—White flowers in June. Height, 2 ft.

LEYCESTERIA. FLOWERING NUTMEG.
L. formosa.—White and purple flowers in August. Height, 4–6 ft.

LIGUSTRUM. PRIVET.
L. coriaceum.—White flowers in June. Height, 3–6 ft.
L. Ibota (*E.*).—White flowers in June. Height, 3 ft.
L. japonicum (*E.*).—White flowers in June. Height, 6 ft.
L. lucidum (*E.*).—White flowers in June. Height, 8 ft.
L. ovalifolium (*E.*).—The OVAL-LEAVED PRIVET, with white flowers in June. Height, 6–12 ft.
L. Quihoui.—White flowers in June. Height, 6 ft.
L. sinense (*E.*).—White flowers in June. Height, 6–8 ft.
L. vulgare (*E.*). — The COMMON PRIVET, with white flowers in June. Height, 6–10 ft.
L. vulgare aureum[1] (*E.*). — The GOLDEN PRIVET, with white flowers in June and golden foliage. Height, 6–10 ft.

LIQUIDAMBAR. See article on *TREES.*

LONICERA. HONEYSUCKLE. See also article on *CLIMBING AND TRAILING PLANTS.*
L. Albertii.—Rosy flowers in June. Height, 3–6 ft.
L. Maackii.—White flowers in June. Height, 4 ft.
L. nitida (*E.*).—White flowers in June. Height, 2–6 ft.
L. pileata.—White flowers in June. Height, 1 ft.
L. tatarica.—Pink flowers in April. Height, 6–10 ft.
L. thibetica.—Pink flowers in April. Height, 3 ft.

MAGNOLIA. See also articles on *CLIMBING AND TRAILING PLANTS* and *TREES.*
M. hypoleuca.—White flowers in June. Height, 10–20 ft.

[1] Several other varieties of *L. vulgare* might well be grown if space admits.—EDITOR.

M. Lennei.—Rose flowers in April. Height, 5–15 ft.
M. obovata. — Purple and white flowers in April. Height, 6 ft.
M. parviflora.—White and rose flowers in June. Height, 6–10 ft.
M. soulangeana.—White tinted purple flowers from March to May. Height, 10–25 ft.
M. stellata.—White or rose flowers in March. Height, 3–6 ft.
M. Watsoni.—White flowers in June. Height, 6–10 ft.

MENZIESIA. See also DABOËCIA.
M. globularis.—Brown flowers in May. Height, 6 ins.

MYRTUS. MYRTLE. See also article on *MYRTLE*.
M. communis in variety (*H.H.E.*).—The COMMON MYRTLE, with white flowers in June. Height, 4–10 ft.

NEILLIA.
N. amurensis.—White flowers in June. Height, 5 ft.
N. opulifolia. — The NINE-BARK, with white flowers in June. Height, 5–8 ft.

NOTOSPARTIUM.
N. Carmichaeliae (*H.H.E.*).—Pink flowers from June onwards. Height, 4–10 ft.

NUTTALLIA.
N. cerasiformis.—The OSO BERRY, with white flowers from March onwards. Height, 4–6 ft.

OLEARIA. DAISY BUSH.
O. Haastii (*H.H.E.*).—White flowers from July to August. Height, 3–8 ft.
O. ilicifolia (*H.H.E.*). — White flowers from July onwards. Height, 2–6 ft.
O. macrodonta (*E.*).—White flowers from July onwards. Height, 2–6 ft.
O. nummularifolia (*E.*). — White flowers in July. Height, 3 ft.
O. stellulata (*H.H.E.*).—The STARRY DAISY BUSH, with white flowers from June onwards. Height, 2–6 ft.

ONONIS. REST HARROW. See also separate article.
O. fruticosa (*H.H.E.*).—Pink flowers from May onwards. Height, 2 ft.

OSTEOMELES.
O. anthyllidifolia (*E.*). — White flowers in July. Height, 6–20 ft.

OXYCOCCUS. CRANBERRY.
O. macrocarpus. — The AMERICAN CRANBERRY, with pink flowers in May. Height, 9 ins.
O. palustris.—The CRANBERRY, with pink flowers in May. Height, 6 ins.

PAEONIA. PAEONY or PEONY. See also article on *PAEONY*.
P. lutea.—Yellow flowers in June. Height, 2 ft.
P. Moutan in variety.—The MOUTAN or TREE PAEONY, with purple to white flowers in May. Height, 3–6 ft.

PALIURUS. CHRIST'S THORN.
P. australis (Syns. *P. aculeatus* and *P. Spino-Christi*).—Greenish flowers in June. Height, 4 ft.

PARROTIA.
P. persica.—Scarlet flowers in June. Height, 6–15 ft.

PERNETTYA.
P. mucronata in variety.—Berries from white to purple. Height, 2–6 ft.

PHILADELPHUS. MOCK ORANGE.
P. coronarius in variety.—White flowers in May. Height, 8 ft.
P. Coulteri.—White flowers in May. Height, 6 ft.
P. gordonianus.—White flowers in July. Height, 6–10 ft.
P. grandiflorus.—White flowers in June. Height, 6–15 ft.
P. hirsutus.—White flowers in June. Height, 3–6 ft.
P. Lemoinei in variety.—White to rose flowers in June. Height, 3–8 ft.
P. Lewisii.—White flowers in June. Height, 3–6 ft.
P. microphyllus.—White flowers in June. Height, 2–4 ft.
P. Satsumi.—White flowers in July. Height, 5 ft.

PHILLYRAEA.
P. angustifolia (*E.*).—White flowers in May. Height, 8 ft.
P. decora (*E.*).—White flowers in May. Height, 6 ft.
P. latifolia in variety (*E.*).—White flowers in May. Height, 6–15 ft.
P. media in variety.—White flowers in May. Height, 6–15 ft.

PHLOMIS. JERUSALEM SAGE. See also separate article.
P. fruticosa (*E.*).—Yellow flowers in June. Height, 3 ft.

PHOTINIA.
P. serrulata.—White flowers in May. Height, 6–10 ft.

PIERIS.
P. floribunda (*E.*).—White flowers in April. Height, 2–6 ft.
P. formosa (*E.*).—White flowers in April. Height, 3 ft.

P. japonica.—White flowers in May. Height, 3–6 ft.
P. mariana.—The STAGGER-BUSH, with white flowers in May. Height, 4 ft.
P. nitida.—White to purple flowers in March. Height, 6 ft.
P. ovalifolia (*H.H.E.*). — Pinkish flowers in May. Height, 2 ft.

PLAGIANTHUS. WHAU-WHI.
P. Lyalli (*H.H.E.*).—White flowers in June. Height, 6–15 ft.

POTENTILLA. CINQUEFOIL. See also separate article.
P. Friedrichseni.—Yellow flowers in July. Height, 2–4 ft.
P. fruticosa.—Yellow flowers in July. Height, 3–5 ft.
P. Veitchii.—White flowers in July. Height, 3–6 ft.

RAPHIOLEPIS. See article on *CLIMBING AND TRAILING PLANTS.*

RHODODENDRON. See separate article.

RHODOTYPOS.
R. kerrioides. — White flowers in April. Height, 6–15 ft.

RHUS. SUMACH.
R. copallina.—The DWARF SUMACH, with greenish flowers in August. Height, 6–8 ft.
R. cotinoides.—The CHITTAM WOOD or SMOKE BUSH, with purple flowers in June. Height, 6 ft.
R. Cotinus in variety.—The VENETIAN SUMACH, with purple flowers in June. Height, 6 ft.
R. glabra.—The SMOOTH SUMACH, with greenish flowers in August. Height, 8 ft.
R. Osbeckii.—White flowers in June. Height, 8–15 ft.
R. Toxicodendron.[1]—The POISON IVY or POISON OAK, with greenish flowers in June. Height, 1–2 ft.
R. typhina in variety.—The STAGHORN SUMACH, with green and yellow flowers in July. Height, 8–15 ft.
R. venenata.[2]—The POISON SUMACH, with green flowers in July. Height, 6–18 ft.
R. vernicifera.—The LACQUER TREE, with green and yellow flowers in July. Height, 10 ft.

RIBES. CURRANT and GOOSEBERRY. See article on *BUSH FRUITS.*
R. alpinum in variety. — Green flowers in May. Height, 2 ft.
R. aureum. — The BUFFALO or MISSOURI CURRANT, with yellow flowers in May. Height, 6 ft.
R. gordonianum.—Yellow and red flowers in May. Height, 6 ft.
R. Grossularia in variety.—The GOOSEBERRY. See article on *BUSH FRUITS.*
R. nigrum.—The BLACK CURRANT. See article on *BUSH FRUITS.*
R. rubrum.—The RED CURRANT. See article on *BUSH FRUITS.*
R. rubrum album.—The WHITE CURRANT. See article on *BUSH FRUITS.*
R. sanguineum in variety.—The FLOWERING CURRANT, with flowers from red to white in April. Height, 6 ft.
R. speciosum (*H.H.E.*).—Crimson flowers from May to July. Height, 4–6 ft.

ROMNEYA. TREE POPPY. See also separate article.
R. Coulteri.—White flowers from June onwards. Height, 3–6 ft.
R. trichocalyx.—The CALIFORNIAN TREE POPPY, with white flowers from June onwards. Height, 3–6 ft.

ROSA. See articles on *ROSE, ROSE CLASSES, ROSE SPECIES,* etc.

ROSMARINUS. ROSEMARY. See also article on *POTHERBS.*
R. officinalis in variety.—The ROSEMARY, with aromatic leaves. Height, 4 ft.

RUBUS. BRAMBLE and RASPBERRY.
R. biflorus.—White flowers in May. Height, 3–6 ft.
R. caesius.—The DEWBERRY, with white flowers in June. Height, 2 ft.
R. canadensis.—The LOW BLACKBERRY or LOW BRAMBLE, with white flowers in June. Height, 3 ft.
R. deliciosus.—White flowers in June. Height, 3 ft.
R. fruticosus in variety.—Pink to white single and double flowers in July. Height, 6–10 ft.
R. laciniatus.—White flowers in July. Height, 6–10 ft.
R. nutkanus.—The SALMON-BERRY, with white flowers in August. Height, 4 ft.
R. occidentalis. — The THIMBLEBERRY, with white flowers in May. Height, 5 ft.
R. odoratus.—The PURPLE-FLOWERING RASPBERRY, with purple flowers from June onwards. Height, 3–8 ft.

[1] Poisonous to handle.—EDITOR.
[2] Very poisonous to handle.—EDITOR.

R. phoenicolasius.—Pink flowers in June. Height, 6–10 ft.
R. strigosus.[1] — The WILD RED RASPBERRY, with white flowers in June. Height, 3–4 ft.
R. trivialis.[1] — The LOW BUSH BRAMBLE, with white flowers in July. Height, 2 ft.
R. villosus.—The HIGH BLACKBERRY, with white flowers in July. Height, 4 ft.

RUTA. RUE. See also articles on *POTHERBS* and *RUTA*.
R. graveolens.—The COMMON RUE, with yellow flowers in June. Height, 2–3 ft.

SALIX. See article on *TREES*.
SAMBUCUS. See article on *TREES*.
SENECIO. See also separate article.
S. Grayii (*H.H.E.*).— Yellow flowers in June. Height, 2 ft.
S. laxifolius (*H.H.E.*). — Yellow flowers in June. Height, 2 ft.

SHEPHERDIA. BUFFALO BERRY and RABBIT BERRY.
S. argentea.—Yellow flowers in April. Height, 6–10 ft.
S. canadensis (*H.H.E.*).—Yellowish flowers in April. Height, 10 ft.

SKIMMIA.
S. Fortunei (*E.*).—Scarlet berries in the autumn. Height, 3 ft.
S. japonica (*E.*).—Scarlet berries in the autumn. Height, 3 ft.
S. oblata. — Scarlet berries in the autumn. Height, 3 ft.

SOPHORA.
S. heptaphylla.—Yellow flowers in October. Height, 6 ft.
S. japonica in variety.—White flowers in August. Height, 10–20 ft.
S. macrocarpa (*H.H.E.*).—Yellow flowers in April. Height, 6 ft.
S. tetraptera (*H.H.E.*).—The HOUMA, with yellow flowers in May. Height, 12 ft.

SPARTIUM. SPANISH BROOM.
S. junceum.—The YELLOW SPANISH BROOM, with yellow flowers in August. Height, 6 ft.

SPIRAEA. See also separate article.
S. Aitchisoni.—White flowers in August. Height, 6–12 ft.
S. arguta.—White flowers from March onwards. Height, 6 ft.
S. ariaefolia.—White flowers in June. Height, 8 ft.
S. bella.—Red flowers in July. Height, 2 ft.
S. betulifolia.—Pink flowers in June. Height, 2 ft.
S. bullata.—Pink flowers in July. Height, 1½–2 ft.
S. cana.—White flowers in June. Height, 1½ ft.
S. canescens. — White flowers in June. Height, 6–8 ft.
S. cantoniensis.—White flowers in June. Height, 4–8 ft.
S. chamaedrifolia in variety.—White flowers in June. Height, 4 ft.
S. crenata.—White flowers in April. Height, 4 ft.
S. decumbens.—White flowers in June. Height, 1½ ft.
S. discolor.—White flowers in June. Height, 8 ft.
S. Douglasi.—Pink flowers in August. Height, 6 ft.
S. Hacqueti. — White flowers in June. Height, 1 ft.
S. hypericifolia in variety.—White flowers in April. Height, 5 ft.
S. japonica in variety.—Flowers from red to white in July. Height, 4–6 ft. Its variety *Bumalda* has red flowers.
S. laevigata.—Red flowers in May. Height, 4–6 ft.
S. lindleyana.—White flowers in September. Height, 6–8 ft.
S. prunifolia fl. pl.—White flowers in April. Height, 4–6 ft.
S. pubescens.—White flowers in May. Height, 6 ft.
S. salicifolia in variety.—White flowers in July. Height, 5 ft.
S. sorbifolia.—White flowers in August. Height, 4 ft.
S. Thunbergi.—White flowers in March. Height, 1–3 ft.
S. tomentosa.—The HARDHACK or STEEPLE-BUSH, with white flowers in August. Height, 5 ft.
S. trilobata.—White flowers in May. Height, 3 ft.
S. Van Houttei.—White flowers in May. Height, 2–4 ft.
S. Wilsonii.—White flowers in June and July. Height, 6 ft.

STACHYURUS.
S. praecox.—Pink flowers in April. Height, 6–10 ft.

STAPHYLEA. BLADDER-NUT.
S. colchica.—White flowers in June. Height, 6 ft.
S. Coulombieri. — White flowers in June and July. Height, 6 ft.
S. pinnata.—The BLADDER-NUT, with white flowers in June. Height, 6 ft.

[1] These are only suitable for the wild garden.—EDITOR.

S. trifolia.—The American Bladder-nut, with white flowers in May. Height, 6 ft.

STEPHANANDRA.

S. flexuosa.—White flowers in July. Height, 8–15 ft.

S. Tanakae.—White flowers in July. Height, 6–8 ft.

STRANVAESIA.

S. glaucescens (*H.H.E.*).—White flowers in July. Height, 8–15 ft.

S. undulata.—White flowers in July. Height, 6–15 ft.

STUARTIA.

S. pentagyna.—Cream flowers in June. Height, 6–10 ft.

S. Pseudo-camellia.—White flowers in June. Height, 8–10 ft.

S. virginica.—White flowers in April. Height, 8 ft.

STYRAX. Storax.

S. americanum in variety.—White flowers in June. Height, 6 ft.

S. grandifolium.—White flowers in June. Height, 6 ft.

S. Obassia.—White flowers in June. Height, 6–10 ft.

S. officinale.—The Storax, with white flowers in July. Height, 12 ft.

S. serrulatum.—White flowers in April and May. Height, 6–20 ft.

S. Wilsonii.—White flowers in April. Height, 6–12 ft.

SYMPHORICARPUS. Snowberry.

S. Heyeri.—Pink flowers in July. Height, 6 ft.

S. occidentalis.—The Wolf-berry, with pink flowers in July. Height, 6 ft.

S. orbiculatus (Syn. *S. vulgaris*).—The Coral-berry or Indian Currant, with white flowers in August. Height, 6 ft.

S. racemosus.—The Snowberry, with rose flowers in August. Height, 6 ft.

S. vulgaris. See *S. orbiculatus.*

SYRINGA. Lilac.

S. chinensis in variety.—The Rouen Lilac, with violet to white flowers in May. Height, 6 ft.

S. Emodi in variety.—White flowers in April. Height, 8–10 ft.

S. japonica.—White flowers in May. Height, 4–8 ft.

S. Josikaea.—Lilac flowers in June. Height, 8 ft.

S. persica in variety.—The Persian Lilac, with purple to white flowers in May. Height, 5 ft.

S. vulgaris in variety.—The Common Lilac, with purple to white flowers in May. Height, 8–20 ft.

TAMARIX. Tamarisk.

T. gallica.—The Common or French Tamarisk, with rosy-pink flowers in July. Height, 6–10 ft.

T. hispida.—Rosy-carmine flowers in July. Height, 6 ft.

T. Pallasii.—Red flowers in July. Height, 8 ft.

T. tetrandra.—Whitish-pink flowers in July. Height, 6 ft.

TEUCRIUM. — See also separate article.

T. fruticans (*H.H.E.*).—Blue flowers in July. Height, 3 ft.

TRICUSPIDARIA (Syn. *Crinodendron*).

T. dependens (*H.H.E.*).—White flowers in June. Height, 6 ft.

T. hexapetata, Syn. *Crinodendron Hookeri* (*H.H.E.*). — Crimson flowers in June. Height, 4–10 ft.

ULEX. Furze, Gorse, or Whin.

U. europaeus.—The Common Furze, etc., with yellow flowers in spring, summer, and autumn. Height, 6 ft.

U. nanus (Syn. *U. europaeus nanus*).—The Cat Whin or Dwarf Gorse, with yellow flowers in July. Height, 12–18 ft.

VACCINIUM.

V. arboreum.—The Farkle-berry, with white or red flowers in May. Height, 6 ft.

V. Arctostaphylos (*E.*).—The Bear Berry, with greenish-white flowers in May. Height, 6 ft.

V. canadense (*E.*).—The Canadian Whortleberry, with white and red flowers in May. Height, 1 ft.

V. corymbosum in variety (*E.*).—The Blueberry, Common Blueberry, or Swamp Blueberry, with white flowers in May. Height, 7 ft.

V. Myrtillus (*E.*).—The Bilberry, Blaeberry, or Whortleberry, with pink flowers in May. Height, 1½ ft.

V. ovatum (*E.*).—Rose flowers in May. Height, 3–5 ft.

V. parvifolium (*E.*).—The Dwarf Blueberry, with pinkish flowers in May. Height, 1 ft.

V. pensylvanicum (*E.*).—White or lilac flowers in May. Height, 2–4 ft.

V. stamineum (*E.*).—The Deerberry, with white flowers in May. Height, 2 ft.

V. Vitis-idaea (*E.*).—The Cowberry,

with pink flowers in May. Height, 9 ins.

VERONICA. SPEEDWELL. See also separate article.

V. amplexicaulis.—White flowers in July. Height, 1–2 ft.

V. anomala (*E.*).—White flowers in July. Height, 3–6 ft.

V. Armstrongii (*E.*).—White flowers in July. Height, 1–3 ft.

V. balfouriana (*E.*).—Violet flowers in June. Height, 2–3 ft.

V. Bidwillii (*E.*).—Pale violet flowers in July. Height, 6 ins.

V. buxifolia (*E.*).—White flowers in June. Height, 2–3 ft.

V. carnosula (*E.*).—White flowers in June. Height, 1 ft.

V. chathamica (*H.H.E.*).—Purple flowers in July. Height, 1 ft.

V. Colensoi glauca (*H.H.E.*).—White or pinkish flowers in July. Height, 1–3 ft.

V. cupressoides (*E.*).—Violet flowers in July. Height, ½–2 ft.

V. decumbens (*E.*).—White or pink flowers in July. Height, 1 ft.

V. elliptica (*H.H.E.*).—White flowers in July. Height, 3–5 ft.

V. epacridea (*E.*).—White flowers in July. Height, 6 ins.

V. Fairfieldii (*E.*).—Lavender flowers in July. Height, 1–1½ ft.

V. formosa (*H.H.E.*).—Blue flowers in July. Height, 2–4 ft.

V. fruticulosa (*E.*).—Flesh-coloured flowers in July. Height, 6 ins.

V. Hectori (*E.*).—White and lilac flowers in June. Height, ½–2 ft.

V. hulkeana (*H.H.E.*).—Lilac flowers in July. Height, 1–3 ft.

V. Kirkii.—White flowers in July. Height, 5–10 ft.

V. Lewisii (*E.*).—White or purple flowers in July. Height, 3–6 ft.

V. Lindsayi (*E.*).—Pink flowers in July. Height, 1 ft.

V. loganioides (*E.*).—White flowers in May. Height, 1 ft.

V. parviflora (*H.H.E.*).—The KOROMIKO, with white or blush flowers in July. Height, 1–5 ft.

V. pimeleoides (*E.*).—Purple flowers in July. Height, ½–1 ft.

V. pinguifolia (*E.*).—White flowers in June. Height, 1 ft.

V. rakaiensis (*E.*).—White flowers in June. Height, 3–6 ft.

V. salicifolia (*H.H.E.*).—The KORUMEEK, with white or purplish flowers in July. Height, 2–6 ft.

V. saxatilis (*E.*).—Blue flowers in June. Height, 6 ins.

V. speciosa in variety (*H.H.E.*).—Purplish-blue flowers in July. Height, 3–6 ft.

V. Traversii (*E.*).—Whitish flowers in June. Height, 3–8 ft.

V. vernicosa (*E.*).—White flowers in July. Height, 1–4 ft.

VIBURNUM.

V. acerifolium.—The DOCKMACKIE, with white flowers in July. Height, 4 ft.

V. Carlesii.—White flowers in June. Height, 3–6 ft.

V. davuricum.—White flowers in June. Height, 2 ft.

V. dentatum.—The ARROW-WOOD, with white flowers in June. Height, 6 ft.

V. dilatatum.—White flowers in June. Height, 10 ft.

V. Lantana in variety.—The WAYFARING TREE, with white flowers in May. Height, 10 ft.

V. lantanoides.—The HOBBLE-BUSH, with white flowers in June. Height, 5 ft.

V. macrocephalum.—White flowers in June. Height, 8–20 ft.

V. nudum.—The WITHE ROD, with white flowers in June. Height, 8 ft.

V. odoratissimum (*H.H.E.*).—White flowers in May. Height, 2 ft.

V. Opulus in variety.—The GUELDER ROSE, with white flowers in July. Height, 10 ft.

V. Opulus sterile.—The SNOWBALL TREE, with white flowers in July. Height, 10 ft.

V. prunifolium.—The BLACK HAW, with white flowers in May. Height, 8 ft.

V. rhytidophyllum (*E.*).—Yellowish-white flowers in June. Height, 6–8 ft.

V. Sieboldii (Syn. *V. tomentosum Sieboldii*), with white flowers in May. Height, 6 ft.

V. stellulatum.—White flowers from May to July. Height, 12–20 ft.

V. Tinus in variety.—The LAURUSTINUS, with white flowers in July. Height, 5 ft.

V. tomentosum Mariesi.—White flowers in May. Height, 6 ft.

V. utile (*E.*).—White flowers in April. Height, 4–6 ft.

VINCA. PERIWINKLE. See also separate article on *PERIWINKLE*.

SIDALCEA (Nat. Ord. Malvaceæ)
This genus is comparatively little known, or only grown in large collections, and more is the pity, for it contains some lovely species of hardy perennial plants grand for cutting, and splendid for use in the herbaceous, perennial, or mixed border. Its culture is a matter of considerable ease. It will thrive splendidly in common, rich garden soil, provided this is not too cool and moist, and is easily propagated by seeds sown in the usual way for other hardy perennials in the spring or early summer. It may also be propagated by division of the root-stocks in the autumn or spring, at which latter period it may be most successfully planted. The following is a selection of the best species:—

Sidalcea candida.—This bears large pure-white spikes of bloom from June to September, and averages 1 yd. in height.

S. humilis.—Syn. *S. malvaeflora*, which see.

S. Listeri.—This bears fringed flowers of soft pink from July to September, and grows 3–4 ft. high.

S. malvaeflora (Syn. *S. humilis*).—This bears in its several forms, soft pink, rosy-red, or rosy-purple flowers from July to September, and grows 2–4 ft. high. Its variety *delphinifolia* has finer foliage.

S. spicata (Syn. *S. murrayana*).—This bears erect spikes of pink flowers from July to early October, on plants 2–4 ft. high.

SIEGLINGIA.—Now included in the genus *TRIODIA.*

SIEVE-TUBES.—See under TISSUES in *PLANT PHYSIOLOGY.*

SIEVERSIA.—Now included in the genus *GEUM.*

SIEVES.—See *GARDEN APPLIANCES.*

SILAUS (Pepper Saxifrage. Nat. Ord. Umbelliferæ).—On account of the word "Saxifrage" forming part of the English name of this genus of hardy perennials, unwary amateurs often purchase it in the hope that they are getting something choice. Various species, such as *S. carvifolius* (Syn. *S. virescens*), *S. flavescens* (Syn. *S. pratensis*), and *S. tenuifolius* are grown at Kew, all of them valueless from a decorative point of view.

SILENE (Campion, Catchfly, etc. Nat. Ord. Caryophyllaceæ).—This genus contains numerous hardy annual species, but few of these are of real garden value. It also contains many species useful for the perennial border and rock garden.

Annual Species.—These are best sown out of doors in April for summer flowering, and in August or September for spring blooming. They succeed best if transplanted into their flowering positions 6 ins. apart each way. All the varieties of *Silene pendula* are of neat compact growth, and are particularly suitable for spring bedding in association with daffodils, hyacinths, and tulips.

Silene gallica.—A useful, pink, summer blooming species about 18 ins. high.

S. pendula.—Both double and single forms of this are available. The type is a rose or crimson summer blooming plant growing 12 ins. high. *Bonnetti* is one of the best named varieties, with rose-coloured flowers. Other available coloured forms include white, pink, peach, red, and crimson.

Perennial Border Species.—These, which may also be grown in the rock garden, require the usual treatment for perennials and are propagated by seed sown in the usual way, or by division of the roots in the autumn or spring. All are suitable for the front portions of borders or edgings, etc. Good light soil and a sunny site are the essentials to success. A selection of useful sorts is given, but for a complete list of the numerous species larger works must be consulted :—

Silene altaica.—A yellow sort flowering in August and growing 12 ins. high.

S. amoena.—A white sort blooming in July and August. Height, 12 ins.

S. Asterias.—A desirable red July blooming sort about 12 ins. high.

S. cana.—A crimson or red sort flowering in June and July about 15 ins. high. *S. italica* of some.

S. corsica.—A little known desirable purple sort flowering in June and July, which averages 12 ins. high.

S. elata.—A tall white June flowering sort about a yard high.

S. laciniata.—A useful scarlet July blooming species about half a yard high.

S. maritima.[1]—A sort with white or reddish flowers coming in during July and August. Height varies from 4–12 ins. The double variety *S. maritima flore pleno* is attractive.

S. pennsylvanica.—A red June flowering sort about 12 ins. high.

S. regia.—A rather attractive crimson sort flowering from June onwards and averaging half a yard in height.

S. repens.—A useful pink sort blooming in August and September. It grows about 12 ins. high.

S. Schafta.—An exceedingly useful rose-coloured sort flowering from June to September, and ranging in height from 4–8 ins.

Rock Garden Species.—The following eight species are selected

[1] This is popularly called Witches' Thimble.—Editor.

from a very large number which are available. They are propagated chiefly by division of the roots in the spring. Many also come freely from seeds sown in gentle heat in March.

Silene acaulis (Moss Campion or Cushion Pink).—This forms hillocks of pale green foliage. Flowers rosy-pink. Site open. Soil very gritty, moist. Flowering Period, June to August. Height, 2 ins.

S. alpestris.[1]—This has tufts of narrow green leaves. Flowers white. Site sunny. Soil rich, gritty. Flowering Period, May to July. Height, 4 ins.

S. Elizabethae.—This forms tufts of broad leaves. Flowers rose-pink, petals two-lobed. Site sunny. Soil rich, gritty. Flowering Period, June to July. Height, 4 ins.

S. Hookeri.—A dwarf plant. Flowers deep rose coloured, fringed petals. Site, half-shade. Soil sandy loam. Flowering Period, July. Height, 3 ins.

S. Pumilio (Pygmy Catchfly).—Like *S. acaulis* in habit. Flowers rose coloured and large. Site sunny. Soil gritty. Flowering Period, May to June. Height, 2 ins.

S. quadrifida.—Like *S. alpestris*, but much smaller, in habit and flowers.

S. Saxifraga.—A tufted spreading plant. Flowers white, tinged with red beneath. Site sunny. Soil gritty loam. Flowering Period, May to August. Height, 6 ins.

S. virginica (Fire Pink).—This has rosettes of leaves and trailing stems. Flowers vivid crimson-scarlet. Site, half-shade. Soil deep, well-drained. Flowering Period, June to August. Height, 6 ins.

SILPHA.—A genus of beetles of which the Beet Carrion Beetle is one.

SILPHIDÆ.—See Beet Carrion Beetle in *Insect Pests*.

SILPHIUM (Rosin Weed. Nat. Ord. Compositæ).—There are undoubtedly many better hardy perennial plants than the Silphiums, but as we should be much criticised by enthusiasts of hardy plants if the genus was omitted, we propose to describe a few species here, though for several others larger works must be consulted. The plants, which resemble Sunflowers in some respects, had some medicinal value in the olden days.

Culture.—No difficulty whatever in the culture of Silphiums will be found, given a garden soil of average quality and a sunny site. The taller sorts should be put well back in the herbaceous borders or, better still, relegated to the wild garden, where they make rather handsome subjects. Propagation is best effected by division of the rootstocks in the autumn or spring, at which times they may be successfully planted, and lovers of indoor flowers should note that the plants are useful for cutting.

What to Grow.—We recommend the following species as being the most suitable:—

Silphium albiflorum.—This is a pretty white sort blooming from July to September, and growing 3–5 ft. high.

S. connatum.—Syn. *S. perfoliatum*, which see.

S. integrifolium.—This is the dwarfest species of all, and finds favour with many on that account. It bears yellow flowers from late July to September, and grows about 1 yd. in height.

S. laciniatum.—This is the comparatively well-known COMPASS PLANT bearing brilliant yellow flowers from June to October, and growing about 5 ft. high.

S. perfoliatum (Syn. *S. connatum*).—This is popularly known as the CAP PLANT. It bears attractive yellow flowers from July to September, and averages 4–7 ft. in height.

S. terebinthinaceum (PRAIRIE BURDOCK).—This and its variety *pinnatifidum* (Syn. *S. pinnatifidum*) are both somewhat coarse. They bear yellow flowers from June onwards right to the end of the autumn, and average 6–12 ft. in height.

SILVERY CINQUEFOIL (*Potentilla argentea*).—See footnote to article on *POTENTILLA.*

SILVERY REED-GRASS (*Cortaderia conspicua*).—See *CORTADERIA.*

SILYBUM (Nat. Ord. Compositæ). This is a genus of Thistle-like, hardy biennials and perennials thriving anywhere. Unless the collection is very large, they may be dispensed with. *S. eburneum* (Syn. *S. hispanicum*) is the IVORY MILK THISTLE, while *S. marianum* is the common MILK THISTLE. Both bear purplish flowers in the autumn, and average 6–7 ft. in height.

SINGLE COLOUR BEDS.—See *COLOUR GARDENING: SINGLE COLOUR BEDS.*

SINGLE CORDONS.—See *CORDON FRUIT TREES.*

SINGLE ROSES.—See *ROSES FOR ALL PURPOSES.*

SIOUMI (*Daphniphyllum macropodum*).—See *SHRUBS.*

SIPHOCORYNE.—See under APPLE APHIDES in *INSECT PESTS.*

SISYMBRIUM (FLIX-WEED, GARLIC MUSTARD, HEDGE MUSTARD, LONDON ROCKET, etc. Nat. Ord. Cruciferæ).—A very large number of species of this genus have been described by plant collectors and botanists, but as the majority of them are of weedy appearance, and the few remaining are of doubtful hardiness, we do not propose describing them in the present edition of this work.

SISYRINCHIUM (SATIN FLOWER. Nat. Ord. Iridaceæ).—This is a genus of half-hardy and hardy perennials, but those of the former section are omitted, as we do not consider them of sufficient importance to describe. The hardy species

are, however, very useful for the perennial border, rock border, and rock garden. They thrive in ordinary, light, rich garden soil to which vegetable mould has been rather copiously added, and may be propagated without much difficulty by offsets in March or April, and by summer-sown seeds in the usual way. We recommend the following :—

Sisyrinchium angustifolium (Syn. *S. gramineum*, also *S. Bermudianum* of some authorities).—This and its varieties *bellum* (Syn. *S. bellum*) and *Nuttallii* (Syn. *S. Nuttallii* of some authorities) bear blue flowers from May to June, and grow 6–9 ins. high.

S. Bermudianum (Syn. *S. iridioides*).—This, popularly called BLUE-EYED GRASS, bears blue flowers in June, and grows 12 ins. high.

S. gramineum.—Syn. *S. angustifolium* above.

S. grandiflorum.—This is one of the best border species, bearing large purple flowers from March to June, on plants 1 ft. high. Its variety *album* is pure white.

S. iridioides.—Syn. *S. Bermudianum* above.

S. striatum.—This is a useful yellow sort blooming in June, and averaging 1½ ft. in height.

SITE FOR A MARKET GARDEN.—See *MARKET GARDENING*.

SITE FOR ROCK GARDEN.—See *ROCK GARDEN : MAKING A*.

SITE FOR VEGETABLE GARDEN.—See *VEGETABLES : GENERAL CONSIDERATIONS*.

SITKA SPRUCE (*Picea sitchensis*).—See *TREES*.

SITONES.—See PEA AND BEAN WEEVILS in *INSECT PESTS*.

SIUM.—See *SKIRRET*.

SKELETON FRAME.—See *GARDEN FRAMES*.

SKELETON LEAVES.

Fine collections of these can easily be made if the leaves are first soaked in water till the green matter turns soft and putrid, and are then further soaked, after complete cleansing, in a gallon of water to which 30 teaspoonfuls of Chloride of Lime have been added. The first soaking may take several days, perhaps even a week; the latter will, however, serve its purpose in about twelve hours.

SKIMMIA.—For the best species see *SHRUBS*.

SKIRRET (*Sium Sisarum*. Nat. Ord. Umbelliferæ).—This is one of those vegetables which, although very popular among Orientals, find but little favour in this country. It is a true perennial, making very long fleshy roots, which are used in exactly the same way as Salsafy.

Culture.—The plant appears to flourish in any well-dug and properly drained soil, but in the preparation of this, rank or newly made manure should be avoided.

The seed may be sown early in spring where the crop is to mature, or in short drills in a rich bed to be afterwards transplanted. The distance between the rows should be not less than 12 ins., from 9–12 ins. being allowed between the plants in the rows.

Skirret appreciates a moist soil, and for this reason water should be liberally supplied during a hot season, or the roots are likely to lack size and table quality.

At the close of the growing season, a portion of the crop may be taken up and stored as advised elsewhere for *SALSAFY*, or if preferred all may remain in the ground until required for use, giving slight protection to the surface of the bed during very severe weather.—F. R. C.

SLUGS AND SNAILS.

These are two of the gardener's greatest enemies. It is hard to believe the enormous amount of damage they can do, till one sees it. Nothing with a soft sappy stem or young succulent shoots is proof against their attacks, though some subjects are more susceptible than others. All the choicer perennials in the herbaceous border, as well as a great many young annuals when they are just appearing, are food for these creatures. In the vegetable garden, a large number of young crops, especially such as lettuces, spinach, endive, etc., are fair feeding-grounds for these pests.

Fortunately remedies for Slugs and Snails are not far to seek. All authorities agree as to the wisdom of dusting young plants in the spring freely and frequently with lime or soot to ward off these slimy creatures. Some sundriesmen supply rings of zinc to put round perennials, but when one has 10,000 plants or even more, this mode of protection ranks among the most troublesome, and is far too expensive. Choice plants can be "ringed" with ashes or lime, but it is necessary to apply more immediately after rain. Personally we do not favour spreading the ground with cabbage leaves in the hope of finding some of these pests lurking under them next week. We think this form of trap is very unsightly. There is on the market a patent slug and snail trap with which wonders have been done. On the whole, far the best way of clearing the ground of slugs is to dig some naphthalene soil fumigant into it in the autumn and a little more the following spring if need arises.—E.

SMILACINA.—See *FALSE SOLOMON'S SEAL.*

SMILAX (Syn. *Myrsiphyllum.* Nat. Ord. Liliaceæ).—This is a handsome genus of greenhouse and hardy climbing plants with elegant foliage, which are largely used for cutting purposes. Suckers from the roots

in little heat are the best modes of propagation. The best soil is rich, sandy loam, with a little peat or leaf-mould. Temperature needed, 45–55° F.

Greenhouse Species. — The two best of the many grown are :—

Smilax angustifolia. — Greenish-white. Fowers in August. Height, 6 ft.

S. asparagoides.—Greenish-white. Flowers in August. Height, 8–10 ft. This is the most popular species, on account of its long sprays of green foliage.

Hardy Perennial Species. — Not many are of much importance to us, but the species may be grown in the same way as other hardy climbers in ordinary, light, rich garden soil, and are best propagated by suckers.

Smilax aspera, S. Bona-nox verbens, S. glauca (the CARRION-FLOWER), *S. herbacea,* and *S. Sarsaparilla* (the plant producing the well-known " Sarsaparilla ") are the best species. All bear greenish-white flowers in June and July, and range from 3–8 ft. in height. *S. rotundifolia,* the GREENBRIER or HORSE-BRIER, is too coarse for our purpose.

SMUT FUNGI.

The Smut Fungi form a natural group of parasitic fungi belonging to the orders Ustilagineæ and Tilletieæ, and are characterised by the production of a powdery mass of black spores. They are specially common in plants of the grass family (Gramineæ), and the world-wide damage they occasion in barley, maize, oats, and wheat amounts annually to several million pounds sterling. Amongst garden plants, with the exception of the Onion Smut (see article on *ONION DISEASES*), few smuts are really important, but mention may be made of *Ustilago violacea* in species of Dianthus, Lychnis, Saponaria, and Silene ; *U. Scabiosae* in Scabious ; *U. Vaillantii* in Scilla ; *Urocystis Anemones* in Anemone, Hepatica, and Ranunculus ; *U. Colchici* in Colchicum and Muscari ; and *U. Violae* in Viola.

The mass of spores is produced in various parts of the plant. In some cases they occur as long black streaks in the leaves (Grasses, Leeks, Onions, and Sedges) ; in others as gall-like swellings on leaves, petioles, or flower-stalks (Anemone, Maize, and Viola). Spore-production may also take place in the flower, developing in the anthers instead of pollen (Lychnis and Silene), or destroying the ovary as in cereals, with a smutted or bunted ear of corn as the result.

A peculiar feature of smut diseases is that plants may be affected a very long time and yet continue to grow in a healthy manner ; the mycelium of the parasite apparently causing little destruction of the tissues. The method of infection and the life-history varies considerably. In the majority of cases the plants concerned are annual, and infection may take place through flower, leaf, or root. In the case of several perennial plants the smut mycelium is perennial also, and hence the only remedy is the destruction of the plants. This applies to *Ustilago violacea* and *U. Vaillantii.* In the remainder of the flowering plants mentioned above the damage is rarely serious, and if

affected leaves are picked off and the plants grown in a fresh site the disease usually disappears.—A. D. C.

SNAIL MEDICK (*Medicago scutellata*). See *MEDICAGO*.

SNAKEROOT.—See under BISTORT in *MEDICINAL HERBS*.

SNAKES.

The gardener has no use for snakes, which glide about so softly and silently among his plants. The common GRASS SNAKE is, of course, quite harmless, but this cannot be said of the ADDER or VIPER. Bites from this latter snake often have serious consequences, especially if the gardener happens to be a little run down at the time, and when working among herbaceous plants in districts where these snakes are common it is difficult to avoid being bitten. The best treatment is to wash the bite at once, and tie a bandage very tightly above the place to avoid the poison circulating. Medical advice should then be obtained without delay.

SNAKEWEED.—See under BISTORT in *MEDICINAL HERBS*.

SNAPDRAGON.—See *ANTIRRHINUM*.

SNEEZEWORT.—See *HELENIUM*.

SNOW FLIES.—See under CABBAGE WHITE FLY in *INSECT PESTS*.

SNOW AND GARDENING.

If snow is dug into any soil, save the very lightest, much harm will be done, the soil being chilled and rendered unsuitable for sowing or planting for a long period. Trees and shrubs should, as a general rule, be left untouched so far as adhering snow is concerned, except where the fall is so heavy that they may be damaged, in which case it should be shaken off.

SNOW IN SUMMER.—This is one of the names applied to *CERASTIUM*, which see.

SNOWBALL TREE (*Viburnum Opulus sterile*).—See *SHRUBS*.

SNOWBERRY.—The genus SYMPHORICARPUS and *S. racemosus*. See *SHRUBS*.

SNOWDRIFT (*Arabis albida fl. pl.*). See *ARABIS*.

SNOWDROP (*Galanthus*. Nat. Ord. Amaryllidaceæ).—Everyoneknows the Snowdrop. Although autumn flowering varieties and large, early spring flowering varieties are now to be had, it is doubtful if any of them have the charm of the old *Galanthus nivalis* in its single blessedness. No one seems to want the autumn kinds. They are out of place then, except from a collector's point of view. Those who "go in" for them have found a great many beautiful forms, but their beauties require close observation to be seen, and for practical garden purposes may be ignored.

Culture.—Any good garden soil suits Snowdrops. They do well in grass which is not too rank, and are ideal for clothing the ground in thin woodlands. They are too soon over when grown in pots, unless grown all the time in a cold frame, and even then they are often disappointing. Snowdrops dislike being out of the ground for a long time, hence early planting,before the end of September at the latest, is a *sine qua non* in their culture.

What to Grow. — *Galanthus Elwesii*.—This is generally larger than our old *Galanthus nivalis*. Its flowers are white,with inner segments

marked with rich green. They are borne in February, on plants 6–9 ins. high.

G. Ikariae. — This has glossy foliage, and white globular flowers in March. Its height is 6–9 ins.

G. Imperati.—This has large white flowers, with inner segments marked green. It blooms in March, and grows 9 ins. high. Its variety *Atkinsoni* is very useful.

G. nivalis.—This is the COMMON SNOWDROP, or old ENGLISH SNOWDROP, with its charming white flowers. It has a tendency to become double in good soil. Height, 6 ins.

G. nivalis flore pleno.—The double form of the above.

G. plicatus.—This, the CRIMEAN SNOWDROP or PLAITED SNOWDROP, has broad, plicate foliage, white flowers, and is taller than the general run of Snowdrops. Height, 9–12 ins.

J. J. & E. T. E.

SNOWDROP ANEMONE (*Anemone sylvestris*).—See *ANEMONE.*

SNOWDROP TREE.—The genus HALESIA and *H. tetraptera.* See *SHRUBS.*

SNOWDROP WINDFLOWER.—The Kew name of *Anemone sylvestris.* See *ANEMONE.*

SNOWFLAKE (*Leucojum.* Nat. Ord. Amaryllidaceæ).—The best way to describe these flowers is to say they look like giant snowdrops on stilts. They are excellent for cutting, and make a good display either in a border or in a thin woodland. They also do quite well in grass, which must not be mown until their leaves begin to die down.

Culture. — Snowflakes may be grown to perfection in any ordinary, good garden soil. They dislike being disturbed, hence they never or seldom do themselves justice at their first time of flowering after being newly planted. Clumps may be left from six to eight years without disturbance. Bulbs should not be kept out of the ground any longer than is absolutely necessary. The summer flowering variety (*L. aestivum*) does well as a semi-aquatic.

Species and Varieties :—*Leucojum aestivum* (SUMMER SNOWFLAKE).—This bears white flowers, with green spots at lips of the petals, in May, and ranges from 12–18 ins. in height.

L. autumnale.—This, a useful subject for the rock garden, bears white flowers tinted with red in the early spring, on plants 3–9 ins. high.

L. vernum (SPRING SNOWFLAKE).—This is similar to the above, but blooms in March or early April, and grows 9–12 ins. in height.

L. vernum carpaticum is a larger and very distinct form of *L. vernum.* The spots on the ends of the petals are a pretty canary colour, instead of being green as in the type. Old-established plants will produce two or three flowers on a stem. Height, 12–15 ins.—J. J. & E. T. E.

SNOWTREE (*Pyrus nivalis*).—See *TREES.*

SOAP WASHES : Their Use in the Garden.—A very important class of garden spraying material employs Soft Soap as a basis. The exceptions are fungicides having a metallic (usually copper) or sulphur base, and "poisons" for the destruction of "biting" insects. Practically all other washes are for the control of "sucking" insects of which the various forms of Aphis (Green Fly, Black Dolphin etc.) and Psylla (Apple Sucker) are typical. Such insects we may say are not provided with lungs, their functions corresponding to breathing being exercised through their skins. When completely sprayed with a Soft Soap solution they are enveloped in a gelatinous film which suffocates them. To make their destruction

doubly certain it is customary to embody some form of vegetable poison in Soft Soap washes such as Nicotine or Quassia. A vigorous pest rids itself of its asphyxiating envelope if the strength is insufficient, but if the material is accompanied by a poison its efforts to do so are immediately paralysed.

Such poisons are in themselves sufficient to kill pests but mixed with plain water they will not effectively "wet" a plant's leaves. By examination under the microscope the liquor will be found to remain in isolated globules on the hairs or greasy surface of the leaf, and in this form is found quite ineffective as an insect poison. Further, the liquor exhibits a tendency to roll off the leaf much as quicksilver will roll on a plate without wetting it. The addition of Soft Soap, however, gives the liquor a complete covering power; it will thoroughly wet the leaf and leave no part of it and no insect thereon unenveloped. The covering or spreading power of the soap is therefore an additional and essential function.

The effective power of soap in a spray is bound up with the quality of the water. A soap solution added to hard water will first create milkiness in the water, in forming insoluble metallic soap, but pure soap dissolved in pure soft water will give a clear solution. Further additions of soap to hard water will result in the formation of a scum on the surface of the water, and even, in extreme cases of hardness, will throw down a precipitate. As long as any such action takes place, that is to say, that until all the lime or magnesia salts to be acted on are "killed," none of the soap used plays any useful part as a spraying material. The presence of unchanged soap in the water after this action is complete is indicated by its power of forming a "lather" on agitation. When increasing quantities of soap are added to such water, at first no evidence of lather is produced. On further addition of soap, signs of lather observed on agitation will quickly die down, and finally when sufficient soap has been added a "permanent" lather will be produced, which is technically considered as the character of lather which will not die down within five minutes by the clock. The production of such a lather is a sure indication that the water has been thoroughly softened. At this stage a suitable further quantity of soap has to be added to provide the necessary character of lather indicating efficient strength for spraying purposes. This quantity may be represented by 4½ lb. per 100 gals. of original soft (*e.g.* rain) water, or approximately two-thirds of an oz. per gal. Hard waters commonly occurring in this country require a further 2, 4, 6 lb., or even in extreme cases 10 lb., per 100 gals., meaning from say half as much again to twice as much again. Waters requiring more than the highest figure are very rarely met with.

It will thus be seen that there is a great danger of inefficient results from spraying if the character of the water employed is not taken into account. It makes for economy to use rain water as far as possible, and if this is available the minimum quantity of spraying material is required, which must be increased for harder waters. A good working test is the character of the lather, which should be of a very thick creamy nature.

With regard to applying spraying fluids with a soap basis, it will be clear from what has been said above that the insects must not only be actually reached but *entirely enveloped*. Owing to the protecting cover afforded by intervening leaves, the general

instructions as to using heavy drenching sprays are not in themselves sufficient to ensure effective results. What is essential is that a "mist" must be produced entirely enveloping the foliage to be sprayed. Knowing how extremely wetting a "Scotch mist" is, it will be realised that this form of spray will ensure absolute wetting of other parts of a plant irrespective of whether they intervene in each other's path and protect each other. To ensure this form of spray, a modern mist-producing nozzle must be employed on the pump. An ordinary garden rose is practically useless. Furthermore it will be found that the higher the pressure employed, the more effective the spray, and it is strongly recommended that, in all except the smallest gardens, a proper spraying apparatus furnished with a pressure gauge and holding from 4 to 40 gals. of spraying wash be employed. Simpler forms are apt to prove very fatiguing in use, and in practice the necessary pressure is not continuously maintained throughout the spraying operation.—Y. M. C. L.

SOCIAL PEAR SAWFLY.—See *Insect Pests.*

SODA AND SODIUM COMPOUNDS. Though soda is not one of the four essential elements for successful plant growth, and thus cannot be said to be of nearly so great importance as potash, yet, seeing that many plants contain it and indeed require it, we must briefly consider it and its salts. Modern chemistry has shown soda to have a secondary action previously not dreamt of, namely, it can break up insoluble potash compounds such as clays, and change places with the potash, thus liberating it for the use of our crops. It is probable that the advantage resulting from the application of soda is due much more to this chemical change than to the fertilising value of the soda itself, though it must be admitted that a heavy dressing of salt on strong land renders this too sticky to work for some time.

Forms of Soda.—If the gardener looks down a chemical list he will see "Soda—see Sodium," and if he glances at the list of sodium compounds he will, as in the case of Potash and Potassium Compounds, be struck by the great number there are. However, only half a dozen or so of these are useful to him, and all save two of the nine compounds of soda we shall describe are used as fertilisers. As regards natural forms of soda, we mentioned in the article on *Potash* that Kainit contains it, in the form of common salt (*Sodium Chloride*). In Bolivia, Chile, and Peru there is a deposit known as Caliche which is sodium nitrate mixed with such impurities as sulphate of lime, sulphate of soda, iodate of soda, and ordinary salt. Probably the best known to the gardener of all forms of soda is rock or ordinary salt (*Sodium Chloride*). Seaweed and sea sand also contain soda salts.

Application of Soda. — If the chemical action referred to above is desired to be applied to the garden soil, then the soda must be applied in some cheap form in the early winter. Carbonate of soda and sulphate of soda are perhaps the best for winter application, the others (excepting the hydroxide and hydrogen sulphate, which are not, as we shall see, fertilisers) should be used in the spring and summer. With regard to soda-

loving crops we may name tap-rooted crops such as beet, carrots, parsnips; plants of the great cabbage family including kohl rabi and seakale; and stem crops such as celery and leeks, and, of course, asparagus. Crops which are not specially fond of it include peas and beans: crops which strongly dislike salt include potatoes, and of surface crops which appreciate it we may mention spinach and spinach beet. A flower which abhors it is the hollyhock; there are as a matter of fact very few flowers that enjoy much in the way of soda, though they may have weak drinks of phosphate or nitrate of soda occasionally. The effect of summer used soda compounds is to stimulate growth and especially leaf growth.

SODIUM CARBONATE.—This is the first soda compound we need mention. It is not of great value but can be used for digging into the soil in the winter at the rate of 2–3 oz. per sq. yd. Incidentally we may mention that it is an essential ingredient of Burgundy Mixture used for spraying potatoes. Its other use is one of a very different kind. Who has not heard of using washing soda or soda-ash with plenty of hot soapy water for cleaning glass of frames with? As a dressing for onions it is of considerable value; the crushed soda is used at the rate of 1–2 oz. per sq. yd. in wet weather during the growing season.

SODIUM CHLORIDE.—This in its impure form is common table salt of which the gardener's young folks have to "eat another peck before they will be grown up into men and women." Agricultural salt is the usual form this comes in, and this should nearly all dissolve in water when a sample is tested. If much remains undissolved, you are probably paying for the cheaper Gypsum (sulphate of lime). Salt is useful for asparagus beds. One or two ounces per square yard may be scattered over the bed in early April and the same dressing repeated if possible immediately before rain, three weeks or a month later, As a fertiliser for other crops salt can be hoed in at the rate of 1 oz. per sq. yd. during the growing season. Salt is one of the few effectual cures for Clubroot Disease. For this, a peck of salt and about 2 pecks of lime should be forked into each square rod of very badly infected ground a few weeks before planting. Less can be used for milder cases. Salt water can be used as a stimulant (1 oz. per gal.), but nitrate of soda is better. Salt is poisonous to pigs.

SODIUM CYANIDE. — This is cyanide of soda, the equivalent and equally poisonous salt of soda to the potash compound which was described in the article on *Potash*. Sodium Cyanide can be used in the same way and for the same purpose.

SODIUM HYDROGEN SULPHATE.—This is sometimes known by the names of Sodium Bisulphate or sodium acid sulphate. Its uses to the gardener are two in number; firstly, it being a poisonous corrosive compound it makes a wonderful weed killer. For this purpose a strong solution of it is made with hot water and this is applied to weedy garden paths, etc. in dry, hot, summer weather. A second application is rarely necessary unless rain falls immediately afterwards. Secondly, it can be used as a means of dissolving bones. The bones are first of all crushed and two parts by weight are mixed with one part by weight of this sodium sulphate. The whole is then well sprayed with water and allowed to digest for several days. After this the material is turned over with a shovel, put through a riddle, and stood in a dry

place till required for use. This sulphate is largely produced in hydrochloric acid factories where it goes by the name of salt cake. It is also produced in the manufacture of nitric acid from Chile Saltpetre or nitrate of soda, and is then known as nitre cake.

SODIUM HYDROXIDE.—This is caustic soda. It is very burning if it gets on hands or clothes, very few people being able to touch the chemical without their fingers getting burnt. Like caustic potash it can be and is freely used for making up caustic winter washes, and it should be stored in the same way as that chemical.

SODIUM NITRATE is another name for Chile Saltpetre or nitrate of soda. It is a well-known nitrogen fertiliser very quick in its action, and encourages leaf at the expense of fruit or flowers. When crops require to be hastened on, such as is needed in the case of a threatened pest attack, few chemicals are so good as nitrate of soda (excepting of course nitrate of ammonia). It can be hoed into the ground among growing crops at the rate of 1 oz. per 9 sq. ft., or applied in water at the rate of ½ oz. per gallon. The liquid must not touch the foliage of the plants. Nitrate of soda being very soluble in water and easily wasted should never be applied in the winter or no trace of it will be left by next spring. It way be well to point out that nitrate of soda is poison to animals.

A matter of interest to gardeners is the fact that nitrate of soda can be used for making nitrate of potash, which is so much more valuable (see article on *Potash*). Crude chloride of potash can generally be obtained when nitrate of potash is at famine prices,[1] and all we need is a supply of this, some nitrate of soda, a simple contrivance for filtering, and some hot water. To 1 pt. by weight of nitrate of soda add 1½ pts. by weight of boiling water. Next a similar solution of potassium chloride (1 : 3) is made and the two liquids mixed. Salt settles and is filtered off. After this all we need do is to evaporate the liquid till only half of it remains and filter off more salt. The liquid that remains is then all evaporated off and the nitrate of potash stored in tins. It can be further purified if necessary.

Nitrate of soda is at times sold in a very impure condition. Salt is the most common adulterant. This can be discovered by the same method as that described under nitrate of potash in the article on *Potash*. See also article on *Manures*.

SODIUM PHOSPHATE. — The normal phosphate of soda is the only one which concerns us in the present article. It is not nearly so good as phosphate of potash, but it can be used as a stimulant occasionally at the rate of 1 oz. per 2 gals. of water.

SODIUM SILICATE.—Aqueous solutions of this and Potassium Silicate are known as Water Glass. The liquid or semi-solid is often handed on to gardeners after eggs have been preserved in it, but as noted in our companion article on *Potash* it is of very little value.

SODIUM SULPHATE. — Probably the gardener will be struck by the similarity of this to the Glauber's Salts he takes from time to time as a medicine. And no wonder, since the commercial sulphate is an impure form of Glauber's Salt. It is not a largely used chemical or of special value, but can be used occasionally as a stimulant at the rate of 1 oz. in 2–3 gals. of water, or hoed in during the growing season at the rate of 1 oz. per sq. yd. It may be interesting to remark that in large doses it is

[1] This was the case when the present article was written.—Editor.

poisonous to plant life, and that a soil can easily be rendered unfertile by dosing it with this chemical. Some of the deserts abroad owe their barrenness almost entirely to the presence of quantities of sodium sulphate.

E. T. E.

[This last compound is produced in some quantity by heating nitrate of soda with sulphuric acid in the manufacture of nitric acid. It represents one reaction further than when acid sodium sulphate is produced in preparing this acid. It also is known as Nitre Cake, but the name should be reserved in our opinion for the acid salt.—EDITOR.]

SOIL: BURNING.—See BURNING SOIL in *SOIL STERILISATION*.

SOIL CULTIVATION.

The various modes of digging or turning the soil, namely, single and double digging, ridging, etc., have for their object: (1) the mechanical breaking up and loosening of the earth; (2) the letting in of air to sweeten and fertilise it; and (3) the incorporation of manures with its substance. The depth to which this process is carried is a most important point of cultivation, and no surface-culture or feeding can replace the possession of a root-run of say 3 ft. or 4 ft. Depth in digging is generally measured by the number of "spits" or lengths of the spade-blade.

Single digging consists in turning the soil over one spit deep. The spade is driven in nearly upright, and the earth lifted and turned upside down *in situ*. This is sufficient where the ground is in good condition and fairly clear of weeds: it is a good preparation for planting or sowing when the land has been given a winter tillage and left rough until the spring. Further, it is the best method of working in manures of a light or powdery character, such as soot, wood ashes, or lime, which are to be scattered evenly over the surface and then turned in. Stable manure, in a "short" or half-rotted state, may also be dug in thus; but "long" or strawy litter is not so manageable. Though plain digging has various uses, most garden soils require a more thorough treatment preparatory to their cropping, and for all strong-growing and long-standing crops, trenching, as distinguished from ordinary digging, is necessary. In trenching, instead of turning over one depth of the spade, we may go two, three, or even four spades deep, if the quality of the lower strata permits.

Trenching.—The principle of trenching is this: a trench is first dug across one end of the plot to be dealt with: its width must be at least as great as its depth. This is then filled up with mould thrown forward from a second trench immediately adjoining the first: the second in turn is filled from a third, and so on in succession until the whole piece has been turned over to the desired depth. If the whole body of the soil be uniformly good in quality, the lower stratum, to a depth of 2 ft. or 3 ft., may be brought up to the surface; but as a general rule, the lower layers of soil are comparatively raw, sour, and unfertile, and should not be superimposed on the top spit which has been mellowed by atmosphere and the deposit of humus or the decay of vegetable matter. Two spits of fertile soil is an average depth, and is capable of excellent

results; three is a precious possession. The stratum below this is generally called the *subsoil*; in trenching it should not be brought nearer the surface; but should be thoroughly broken up and aerated, and may have some manure worked into it; but it should be left in position at the bottom of the trench. This process, commonly called mock or *bastard-trenching*, is the most generally useful for all but the exceptionally deep and fertile soils.

How to Trench a Plot.—The ordinary method of trenching a small plot is to dig out a trench across one end of it, at right angles to its length, and wheel the excavated earth to the other end, where it is laid in a heap, ready to fill in the last trench when the piece is finished. In dealing with large pieces of ground—say, anything beyond 6 × 10 yds.—it is better to divide the surface into two equal parts lengthways, marking the division by a line or by pegs. The trench is then opened across the end of one of the halves, and the earth is merely thrown in a heap to the right or left on the other section. Trench straight down the first piece till the end is reached; then face about and dig a trench across the second, throwing the soil from this trench into the last trench of the first section. Continue trenching back along the second until it is finished; the last trench being filled up with the earth from the first trench of all, which was thrown on one side at the start. This method saves a great deal of wheelbarrow work and shifting of heavy soil to a distance. In digging the trench, keep its sides nearly vertical, and maintain the same depth and width all through the work, measuring these from time to time with a stick, unless the eye can be trusted for an accurate estimate. In bastard-trenching—one good spit turned over and the subsoil well broken up—the trench may be conveniently 2 ft. 6 ins. across. In real trenching, two spades deep or more, 3–4 ft. will be necessary.

In digging, the size of the clod of earth lifted by the spade should be governed by the purpose for which the ground is required. In "digging down" or "digging fine" in order to form a tilth for sowing or planting at an early date, small spadefuls should be taken, and lumps should be chopped up and knocked in pieces with the blade, ridges and hollows being levelled as the work proceeds. For breaking down previously-dug soil, a fork or a "Canterbury" hoe with three prongs is often more handy than a spade.

Rough Digging and Ridging.—In "digging rough" when the ground is to lie fallow for some time, the clods should be as large and rough as possible. On really heavy soils "ridging" is desirable. By this plan the ground is dug in a series of rough trenches, or furrows, the earth taken out of each trench being thrown up on the strip of soil lying next to it, so that the plot is covered with parallel ridges, sloping to a sharp edge, and intervening hollows. This exposes a larger surface to the weather, and will bring the stiffest clays, after the winter's frost, into a friable state by sowing-time.

It is true economy to get a really good spade, and the full price for the best grade should be paid. The tool should be well-balanced and "handy." For trenching and heavy land it should be full-sized and strongly made: a lighter pattern is useful for mixing composts, making seed-beds, etc. In dealing with stony subsoils or large tree roots which may be encountered in

trenching, a pickaxe or mattock may be required.

The addition of manure is most conveniently made in the process of trenching or digging. For all deep-rooting and hungry crops it is important to manure not only the upper, but the bottom layers of the soil. The manure should be wheeled on to the ground while the surface is dry, or during frosty weather, and should be laid in heaps just clear of the strip to be dug or trenched, so as to avoid treading on it during the work. A layer of dung about 2–3 ins. thick is laid on the bottom of each trench, and roughly turned into the subsoil. Shave off a couple of inches from the surface of the next width of ground, and throw it, upside down, on top of the manured trench, thus burying all weeds, etc., safely out of harm's way. A second layer of manure is now spread on the partly-filled trench, and even a third before it is entirely filled from the succeeding trench. In this way the manure is, to some extent, distributed through the body of the soil, instead of being compressed, as it too often is, into one thin stratum at the bottom of the trench. It is well, for the generality of crops, and particularly for seed-beds, to see that there is no solid manure within the uppermost 3 ins. or 4 ins. of the soil. Stones, roots, perennial weeds, and all rubbish should be thrown out as they are met with, and taken away.

It is all-important that digging and trenching should only be done when the ground is in a suitable state. If the surface is wet after rain, or frozen, or muddy from thaw or melted snow, it is worse than useless to attempt to work on it. The right condition between wet and dry can only be learned by experience; but a good deal depends upon the nature of the soil. A light or sandy loam, with good natural drainage, may be workable the day after heavy rain; while retentive clays may need a week of fine weather to make them negotiable.

Surface Cultivation is almost as important as deep stirring of the ground. The tool chiefly employed for this purpose is the Dutch hoe. This should be kept going in dry weather all through the growing season: it is invaluable for aerating the soil and preventing it caking. A tool with an 8-inch blade should be used for open ground and wide rows; one of 2 ins. or 3 ins. is necessary for work among seedlings. For making drills for small seeds by far the best implement is the "triangular hoe"—a plate of steel with three sharp angles fixed at the end of a handle.

Light soils frequently need consolidating, which is, as a rule, best done by careful treading of the surface, when it is fairly dry. After the ground is made firm, it should be lightly gone over with the flat hoe, to make a "crumb" on the top.

Raking is the operation of clearing off stones, rubbish, and clods of soil from the surface of beds prepared for seeds or planting; it may also be used to some extent for minor levelling of inequalities. It should never be used merely to give a neat finish to plots, as the tilth which it leaves is not nearly so wholesome for plants as the rougher result of the flat or Dutch hoe. SOIL FUMIGATING.

The question of soil fumigating is one upon which there are many opinions, and some confusion exists as to the exact meaning of the term. It is used loosely to imply the clearing of the soil of both pests and diseases, but if diseases such as Clubroot or Wart Disease are to be cleared, usually the material must be applied in much greater quantities Strictly speaking, soil fumigating should be limited to the clearing of the soil of pests, leaving the matter of diseases, many of which require special treatment, to him who has studied diseases.

Taking this as our limitation, we find that there are many chemicals which can be applied for the clearing of the ground pests, and before we proceed to describe their use individually, we give a brief warning which may be useful. This is that soil fumigants should be used as early in the winter as possible, to get the ground thoroughly cleared before the spring, since if they are used shortly before seeds are sown, they may prove detrimental to the young plants and stunt the growth of food crops.

Carbide Refuse.—The first soil fumigant about which we must speak is known as spent carbide or carbide refuse. Every gardener knows that it is produced from acetylene gas plant, but very few know of the great value of this residue as a soil fumigant. Dug in during the autumn or winter it will clear the ground of many of the smaller soil pests, but it should not be relied upon where the ground is full of wireworms. About 1 lb. per sq. yd., or a little less, is a suitable dressing. The rock carbide itself is too violent and dangerous for use.

Carbolic Acid.—This is, as most gardeners know, an extremely corrosive liquid used by the medical man in the case of infectious illnesses. It is, however, of great value as a soil fumigant provided that the dressing is not too strong. Being a liquid, its application is somewhat awkward, and it has to be applied to the infected ground by means of a watering-can. The quantity to apply is a matter of opinion, but for a 36-gal. barrel of water 3 pints of concentrated acid will be quite enough. This liquid is extremely poisonous, so it should all be used up, as if any is left lying about it may be mistaken for water and an accident happen. The strong acid will cause severe wounds in contact with naked flesh. In the case of ground which is very full of soil pests at least 30 gals. of this solution for each sq. rod will be required, and the ground should be immediately forked over, or, better still, trenched to the depth of 15 ins. after application.

Carbon Bisulphide.[1]—This is a soil fumigant which is comparatively little used on account of its dangerous nature. There is no doubt of it being highly effective when properly used, but very great caution must be exercised, and nothing should be planted on the ground for at least two months after an application. The best way to apply it is to peg holes all over the ground about 6–12 ins. apart, and at least 7 ins. deep. A little of the bisulphide, which is an oily liquid, is dropped into each hole, the ground being immediately raked over, and, if possible, covered with boards. This chemical, however, is highly inflammable, and areas treated with it have been known to catch fire even by means of a passing spark from the gardener's

[1] Chemists call this *Carbon Disulphide*.—Editor.

pipe. There is no doubt, however, that it entirely kills all soil pests, and if the ground is terribly ridden with these enemies of the gardener they can be completely got rid of by its use.

Flue Dust.—Fresh flue dust is of great value as a soil fumigant on account of the poisonous gases related to Cyanogen that it contains. Of late flue dust has come to the front as a fertiliser, but it is not safe to use it fresh, as the gas it evolves in the soil will kill plants as well as pests. If, however, it is applied in early November, or at the latest in December, at the rate of about 1 ton for every 300 sq. yds. of ground and forked in at once, all soil pests will speedily die, and the ground will thus be thoroughly purified in time for sowing or planting in March. Recently we were advised to mix it with sewage, and so long as the material is applied early, fresh flue dust may well be mixed with it, but if it is to be used as manure for light soils in the spring the flue dust should be old, otherwise it will be too dangerous to use.

Formaline.—This too is a liquid, but it is highly effective as a soil fumigant. Being very strong and quick to evaporate, however, the gardener must be careful when using it, and any vessel containing the strong solution should be opened out of doors to avoid any possibilities of asphyxiation. If the best formaline is obtained, about 1 qt. to every 20 gals. of water should be used, so that for a 40-gal. cask 2 qts. or ½ gal. will be required. The liquid, after being thoroughly stirred with a wooden pole, should be applied to the infected ground with a watering-can, and great care should be taken not to water more ground than can be turned over in one day. As the gas given off is very irritating to the eyes, nose, and throat, gardeners should protect themselves in some way, or, if possible, borrow an old gas-mask from a soldier who has served in Flanders.

Gaslime. — This is the next material about which we must speak, as it is exceedingly effective as a soil fumigant. It is to be regretted that gas is now purified in all up-to-date works by oxide of iron instead of with lime, for the consequence is that little gaslime is now available. Where, however, gas is still purified in the old-fashioned way, and the soil is full of pests, full advantage should be taken of the gaslime, by using it on the ground. Certainly no solid chemical could smell so foul, or more foul, and few liquids can beat gaslime in its odour, except, of course, ammonium sulphide, but the gardener does not think of this when the soil is teeming with wireworms, millepedes, leather jackets, and all other soil pests which greedily devour his crops. Opinions differ as to the amount of gaslime to apply, but personally we believe in doing the thing thoroughly if at all. One gardening writer said the other day that it was the greatest possible danger to apply more than ¼ lb. of gaslime to every sq. yd. of ground, but we believe in putting on 1 lb. to that area, and digging it in at once. It is advisable, however, that the gaslime should be applied as early as possible in November, and certainly not later than the end of December if the soil is to be in a fit state for the receipt of seeds by March. The foolish practice of sprinkling it on the land a month before digging in should not be followed.

Naphthalene.—Many proprietary soil fumigants sold at a price grossly

exceeding their cost, consist largely of naphthalene united with some suitable base, such as lime. As, however, naphthalene is much cheaper than any proprietary soil fumigant in industrial districts where coal is distilled, advantage should be taken of this, and the naphthalene used. Professor Theobald recommends from 2 cwt. to 3 cwt. of naphthalene to be applied to the acre, which works out at from 1 lb. to 2 lb. per sq. rod. Various additions to naphthalene have been suggested from time to time, such as lime, salt, soot, and permanganate of potash, and one soil fumigant which the writer has invented consists of a mixture of one-part lime, one-quarter part salt, and one-eighth part naphthalene. This formula has been published previously for the use of allotment gardeners, and as it has not been registered or put on the market anyone can make it. Its effectiveness for destroying soil pests has been proved to be great.

The main thing to observe in the use of naphthalene, as in most other soil fumigants, is to get the material on the ground and under the ground as early as possible. The gas given off by naphthalene is inflammable, but not so highly inflammable as that of carbon bisulphide. However, it does not do to let the material go off in gaseous form, for much of its effect lies in the searching nature of its gas. So that if it is necessary to store naphthalene for any period, it should be covered with powdered quicklime or stored in air-tight tins. Various mixtures of naphthalene can be used at the rate of $\frac{1}{4}$ lb. per sq. yd., and it is extremely foolish to spread them on the surface of the ground, as many authorities advise, and dig in a week or two later, for by that time nothing but dross will be left.

SALT.—Ordinary common salt has some value as a soil fumigant, though this is not great. It is chiefly useful for killing surface soil pests and slugs, but if dug into the soil at the rate of 2–4 oz. per sq. yd. it will render this distasteful for many soil pests. However, where anything stronger can be obtained, salt should not be relied upon, for it is more of a fertiliser than a soil fumigant.

SOOT.—This too is a mild soil fumigant, but it should not be relied upon. Fresh soot is more effective for the purpose than old soot, but it must not be dusted over plants or it will burn them. Fresh soot can be dug into the ground in the early winter at the rate of about 20 lb. to the sq. rod. It is, of course, difficult to apply, for if there is a slight wind much of it will be blown away. Soot mixed with lime is said to be effective as a soil fumigant on account of the ammonia gas given off, but we prefer naphthalene or something stronger.

TAR.—It very often happens that the asphalters fail to estimate exactly the proportion of fine asphalt needed to cover any one or other of the garden paths, and they leave half a hundredweight or so in a heap behind the tool shed, as it is not worth while carting it away. Rather than let this material go to waste the gardener should spread it on his land, and dig it in as early in the winter as possible. The idea that this material will kill the plants is a popular fallacy, and has no foundation in fact, as from experiments personally made by the writer it had no detrimental effect. As regards its value as a soil fumigant it is worthy of much praise, for the gas given off from the tar means death to all soil pests. It is, of course, difficult exactly to say how much to apply to any area, as this

depends upon the amount of moisture present, but in the writer's experiments he spread the material over the ground in a very thin layer, and dug it in a few weeks later.

There are many other chemicals which find small application as soil fumigants, but with these the gardener need not bother, as most of them are too expensive and too dangerous for general application.

E.

SOIL FUNGICIDES.—See *SPRAYING MIXTURES AND FUNGICIDES.*

SOIL IMPROVEMENT.

To a great extent this is a question of soil working, and to understand the subject of soil working it is necessary that we first of all devote attention to draining, digging, trenching, and especially bastard-trenching. For particulars of how to carry out these operations reference should be made to our articles on *DRAINING* and *SOIL CULTIVATION.*

But besides soil cultivation there are other modes of improvement. The chief of these we mention briefly below :—

Liming.—This is of the greatest importance, and since ground lime can be had cheaply in many districts, allotment holders, and indeed all gardeners, should go in for it extensively. Lime acts like magic as a soil improver, especially on stiff clay, and it quickly leads to a great increase in production. January and February are admittedly the best months for this mode of soil improvement, for fuller details of which reference should be made to our article on *LIME.* It must be noted here, however, that gaslime, often regarded as a soil improver, contains poisonous compounds of sulphur, and should only be applied as a means of killing pests.

Applying Chalk. — It may be mentioned that chalk is much milder in its action than lime, and it is particularly useful for improving light soils or sandy loams. Powdered chalk, not lump, should be used, and it is safe to apply at least 56 lb. to the sq. rod.

Manures.—Of course the best method of soil improvement is by the frequent application of suitable manures and fertilisers, but the *exclusive* use of artificials will end not in improvement, but in soil exhaustion. Artificial fertilisers should be used in conjunction with humus, otherwise the soil will be impoverished. Farm and stable manure are difficult to obtain, but vegetable refuse, including leaves and green manuring (see below), will afford a good basis on which to apply superphosphate of lime and other artificial manures. Light soils in particular are left poorer instead of being improved by the constant use of artificial manures without some form of organic manure, and full particulars as to how to make the material will be found in our article on *VEGETABLE MATTER.*

Green Manuring. — Another splendid way of soil improvement is found in green manuring, and it is safe to assume that this will be far more extensively adopted than it ever has been in the past. To make up for the lack of humus, especially in light sandy soils, quick-growing crops, such as Mustard, Rape, Rye, and, better still, Vetches are drilled in or sown broadcast after clearing the ground, say in late August or September and dug into the ground when green. If a soil is very poor in organic matter, and most light soils are, the gardener cannot do better than to adopt the principle of "growing his own manure." Poor soils have

to be greatly improved if they are not to be worked at a loss, and this means of improving them is as cheap as any, if not cheaper. The subject is discussed at length in its own article.

Marling. — Yet another useful method of soil improvement is known as marling, or sometimes as claying. This is simpler than it sounds, and consists of putting on clay or marl in the early winter. Light soils alone benefit most from this method of improvement, including gravelly soils, which greatly appreciate the addition of clay. Obviously no good purpose would be served by marling soils already full of clay. The material is put on in November as thinly as possible (it is awkward lumpy stuff to spread) at the rate of about 1 cwt. per sq. rod if possible. The frost is allowed full play upon it, and in February or early March the weathered material is dug in, that still in rough lumps being reserved for use on a future occasion.

There are also other modes of soil improvement, such as burning the soil, sterilising it, or fumigating it, and so on. Reference should be made to our articles on *Soil Sterilisation*, *Soil Fumigating*, and *Soil Cultivation*. Methods of improvement bacteriologically and electrically are still in the experimental stage, but there is little doubt that they have a great future before them.

Before closing we give a brief summary of the best ways of improving various soils.

Clay Soils.—These need plenty of strawy stable manure, and vegetable humus of a strawy nature, as well as abundance of lime and road sand, if they are to be improved. The working of such soils should be completed as early as possible in the autumn, and the surface should be left rough for the weather to act upon. Practically all clay soils contain sufficient potash, and the application of wood ashes only tends to make the soil more plastic.

Gravelly Soils.—In these we include chalky and limestone soils, which are invariably thin and poor. The best way to improve them is to manure them heavily with animal manure of whatever sort is available, and to treat the crops growing on them liberally as regards mulches and fertilisers.

Old Black Soils.—Those which have become sour are best improved by liming heavily, and by avoiding the use of dung or acid artificial fertilisers, such as superphosphate of lime and sulphate of ammonia, for a season or so.

Sandy Soils.—To improve these, heavy dressings of sticky humus are essential. Cow or pig dung, pond mud, decayed lawn-mowings, and decomposed vegetable matter should be freely dug in. The working of such soils may be delayed until the spring.

Sour Soils.—These require heavily liming if they are to be improved as described above.—Ht. C.

SOIL STERILISATION.

This important operation does not mean rendering the soil sterile; the aim is to remove harmful vegetable and animal life from the soil so that the choicest plants may be successfully grown.

Two different series of methods may be adopted to this end, first, fumigation of the soil by chemicals (already dealt with under *Soil Fumigating*), and, secondly, physical methods employing heat or cold, which form the subject of the present notes.

Baking. — Where gardening is carried out on a large scale, soil is usually sterilised by being baked or

roasted over pipes containing high-pressure steam. Amateurs cannot do this, so it is necessary to fall back on the old but efficient method of roasting over an open fire. To do this a sheet of iron is laid on bricks over a good red fire, and soil is spread thinly and loosely on it; the baking is finished when the soil is too hot to have the hand pressed on it, and a thick smoke (not steam) is a sign that the operation is going too far. Turf need not be broken up when treated in this way, but simply placed on the plate, grass side down. When the soil is being removed from the plate it should be thoroughly mixed, and allowed to stand at least a day before use.

Burning.—The same principle may be carried out when the yearly bonfire is set alight. Whatever part of the garden is to be treated should be dug up roughly, or, better still, ridged. Prunings, hedge clippings, dry grass, and as much more combustible matter as can be found, should be spread evenly and thickly over the ground, then set alight. If this is done in the late autumn, most of the pests will be near the surface, but they will be eradicated by a good fire. Why burn the rubbish round the corner, then, when such benefits accrue, and when the rich ashes are left to fertilise the soil?

Scalding.—When the soil to be treated is that required for the frame or for tomatoes, cucumbers, carnations, and other greenhouse subjects, another plan, namely, scalding, may be adopted in place of the above. The compost is placed loosely in a box, and boiling water poured through it until that running out of the bottom is appreciably warm. This plan can also be adopted after the pots are filled, though they should be allowed to drain for a day before planting.

An even better way is to fill the compost into pails or metal drums; these are then stood in a tank of boiling water, and left there until the soil becomes unpleasantly hot. This method does not wash away the soluble plant foods, and is infinitely preferable. With half a dozen drums and a good fire many bushels of potting compost can be prepared in a very few hours.

Scalding can only be done after a fashion in the open. A friend of the writer's waters his sweet pea trench and his carnation beds many times with boiling water before he actually needs them, and finds the method is quite efficient, though obviously it is somewhat tedious. Where outdoor soil cannot be baked or burnt as described above, it is preferable to use a soil fumigant.

In all heat sterilised soils initial growth is rather slow, because the process invariably kills a number of the useful soil bacteria as well as the harmful pests and disease spores; but the bacteria soon make headway, and after a brief period the growth of crops in such soils becomes astonishingly rapid.

Effects of Frost.—Extreme cold is almost as effective as extreme heat in killing soil pests, and full advantage of our winters should be taken everywhere. When the garden is dug in the autumn or winter, the surface should be left rough, or, indeed, ridged up as high as possible. (See article on *Soil Cultivation*.) The frost can then penetrate the lumps, and kill most of the pests hibernating there, and if the gardener can find time to re-ridge the soil once or twice so as to expose fresh surfaces, this method of soil sterilising will be more complete. Cold has little or no effect on diseases such as Club-root, Wart Disease, etc. Only heat is effective for destroying them.

H. H. A.

SOIL TESTING.—See *SOILS: THEIR ORIGIN AND NATURE.*

SOILS AND MANURES FOR VEGETABLES.—See *VEGETABLES: GENERAL CONSIDERATIONS.*

SOILS: THEIR ORIGIN AND NATURE. It should be the aim of every horticulturist to understand something of the origin and nature of the soil covering his land. In order to attain this object it is necessary that he should become acquainted with some of the elementary principles of the Science of Geology, which concerns itself with the investigation of the different kinds of rock which make up the solid portion of the earth, and the various agents, biological, chemical, and mechanical, constantly at work in breaking down these rocks, wherever they are exposed at the surface, into the small particles which constitute the soil.

The geologist classifies the rocks as unstratified and stratified. The stratified rocks have all been derived originally from the unstratified in the past history of our earth, and, as the name implies, they are now found in strata, layers, or beds—an arrangement which can be seen in almost any excavation or railway cutting. The three chief types of stratified rocks are the limestones, sandstones, and shales or clays, for we find these rocks, and the soils derived from them, occupy practically the whole of these islands which is under cultivation.

Rocks give rise to soils by a process of breaking down or weathering as it is called, which may be seen and studied in any quarry or cutting where the solid rock is exposed. Suppose the quarry to be in sandstone. Below will be seen the massive rock, which, however, is not solid throughout, but is traversed by divisional planes in three directions approximately at right angles to each other. The most noticeable of these planes run more or less horizontally, and are known to the geologist as bedding planes which represent discontinuity of the deposition of sand when the rock was being formed. Oftentimes these bedding planes are marked by a change in the material making up the rock. At right angles to the bedding planes, and therefore more or less vertical, fissures and cracks known as joints are seen to traverse the rock. These bedding planes and joints split up the rock into cuboidal masses, the size of which differ in different types of rocks. The quarrymen take advantage of these natural planes of division in their operations. The natural agents, which will eventually break up the rock, also take advantage of these planes of weakness. An examination of the rock in the quarry nearer the surface will show how the roots of the plants growing on the surface have penetrated the joints and bedding planes, and by their growth have forced the masses of rocks asunder. Smaller cracks also make their appearance, often occupied by the finer roots of plants, and so the whole rock is being slowly but surely disintegrated by this means. Water falling as rain or snow will percolate through the soil to the underlying rock, and entering the cracks and joints will freeze during the winter, and by so doing exert an enormous pressure tending to widen the openings and so fracture the rock. The masses and fragments of rock so broken off are at first angular, but nearer the surface the angles become less pronounced, due largely to the chemical action of the acids contained in the water which reaches the rock through the soil. By decrease in the size of the rock

fragments and increase in the admixture of decaying vegetable matter derived from the plants which have previously grown on the surface, the rock passes up through the layer known as the subsoil to the soil proper. Mention has been made of the chemical action of the water which percolates through the soil to the underlying rock, and this action will be better appreciated when it is known that water in which carbon dioxide is dissolved is a weak acid, and as such is able to attack successfully almost all the minerals making up the rocks. The most resistant mineral to such action is that known as quartz, which makes up the great bulk of a sandstone, and is familiar as the material making up the sand of the seashore. Rain in falling dissolves some of the carbon dioxide and other gases from the atmosphere, and then obtains a further supply from the decaying vegetable matter in the surface layer of the soil. This decaying vegetable matter also yields some organic acids which aid the chemical action of the water, percolating to greater depths. The roots of the growing plants also have a certain solvent action, since they give off organic acids which attack any rock they root amongst. Burrowing animals do great work by opening up channels from the surface to the subsoil, water and air thus gaining easy access.

Here then can be seen the actual making, in Nature's laboratory, of a soil, and since all soils may be said to have been originally derived from the gradual decay of rocks, it may be correctly inferred that the diversity of soils which occur in different districts is attributable to the fact that the subjacent rocks, which by their decay have yielded the material for the soils, also differ. This is true if the soils are what are known as " residual " or " sedentary " soils—terms which imply that they have been derived directly from the underlying rock. But there is another class known as " soils of transport " which, having been originally derived in the manner already noted in the quarry, have been transported by such agents as ice, water, or wind to greater or less distances from their original source. These soils may bear little or no relation to the underlying rock, unless such rock occupies very large areas, which is not the case with the rocks in England. Large tracts in England north of the valley of the Thames are covered by what is known as boulder-clay, drift, or till, which was brought into its present position and deposited by the ice-sheet which once covered that area. Or again the material known as " alluvium," which makes up the flat expanses or terraces which line our river courses, represents an accumulation of decayed rock which has been transported by the river in past times. In this country, wind is not an important agent of transport, but much of the soil covering Central Europe and Asia, known as " loëss," has been so accumulated, the wind blowing the loose particles from desiccated land surfaces and bringing them together in valleys and plains where vegetation aids in the work of accumulation. It is frequently the case that these transported soils are of great fertility on account of the intermingling of so many different types of rock material.

Having now briefly examined the mode of origin of soil, let us inquire into the nature of the materials which constitute it. The solid substances found in the soils consist either of mineral or of organic matter, the former derived from the decay of rocks, and the latter from

animal and vegetable substances. When rocks decay the minerals are altered and decomposed in varying degrees, some being more resistant than others to the chemical action, as noted above, and these we find in greatest abundance in the soil. Also, the mineral ingredients of the soil vary much in size. The coarse-grained particles are called "sand," and the fine "clay." These terms are not in any way exact, but are merely used for convenience. All soils of the farm and garden will in general be found to consist of varying proportions of sand, clay, limestone, and humus. The relative proportions of the sand and clay particles determine the physical structure of the soil, and upon this to a very large extent depends its suitability or otherwise for cultivation.

Soils may be classified, according to the proportion of sand and clay which they contain, as follows :—

Sandy Loam contains 10 to 40 per cent. of clay particles.
Ordinary Loam contains 40 to 70 per cent. of clay particles.
Clay Loam contains 70 to 85 per cent. of clay particles.
Strong Clay contains 85 to 95 per cent. of clay particles.

If limestone or carbonate of lime is present in a clayey soil to the extent of 5 to 20 per cent., it is termed a *marl*. Should the percentage of limestone present exceed 20 per cent. of the total weight, it becomes a *calcareous* soil. Soils which fall under the head of loam, according to the above classification, make the most suitable soils for all general purposes.

Since sand and clay are of such importance in a study of the soils, it will be advisable to deal with these more in detail.

Sand.—This is a very indefinite term, and is applied generally to any accumulation of particles too coarse to be plastic when wet, and too fine to be called gravel. The term refers simply to the size, and not to the nature of the particles. We can prefix such words as *shell*, *quartz*, or *gem* to the word sand to make it more specific. In general, it may be said that the sand of the garden is quartz sand with some admixture of other minerals, of which the chief are felspar, mica, oxide of iron, and minute quantities of apatite, garnet, rutile, zircon, etc. The felspar and mica are usually more or less altered, and by further decomposition yield iron, lime, magnesia, potash, soda, etc., some of which may be used by plants as food. A pure quartz sand would be quite useless as a soil, but as a constituent of soils it is most valuable, as it tends to make them light and open, and therefore permeable to moisture and air. The sand particles, by absorbing the heat of the sun and communicating it to the lower layers, keep the soil warm.

Clay.—This also is an indefinite term, and is applied to any material which has the property of becoming plastic when moist. There is no sharp line of division between sand and clay. The usual acceptation is that the clay particle is a hydrated silicate of alumina (a term implying the presence of alumina, silica, and water), which is formed during the decomposition of felspar. In its purest form it becomes the kaolin, from which our finest porcelain is made, and which is found as a decomposition product round the granite masses of Cornwall and Devon. Pure kaolin is white, but the clay in our garden soil is variously coloured brown or yellow by oxides of iron. Further, garden clays are always impure, and, like sand, contain many minerals, chief of which is mica. During its de-

composition, this yields iron, magnesia, potash, etc., for plant-food. The physical properties of clay are almost exactly the reverse of those of sand; it is very retentive of moisture, and remains cool, and is therefore able to resist drought.

Soil consisting entirely of clay would be very cold and damp, and in a wet climate would be continually water-logged, excluding air and warmth. As one of the constituents of soil, however, it possesses many valuable properties, among the most important of which may be mentioned its power of absorbing and retaining the useful products resulting from the decomposition of manures, such as ammonia, lime, phosphoric acid, and potash.

Limestone, chalk, carbonate of lime, and calcium carbonate are all names for the same substance, but the last two connote the substance in a purer condition than the first two, which usually have oxide of iron, silica, magnesia, and clay present as well as calcium carbonate. In one form or another carbonate of lime is present in all soils, with the exception of peaty soils and some very open sands. From these last it has been removed, in the first case by uniting chemically with the organic acids of the decaying peat, and in the second case by solution in water containing carbon dioxide. Calcium carbonate is continually being rapidly removed from soil by the action here described, and must be as constantly renewed. One can realise the solution of limestone by visiting the huge caves which have been formed in such limestone districts as the Peak of Derbyshire, Cheddar, or round Ingleborough, simply by the process of solution of the limestone by water charged with carbon dioxide entering the fissures of the rock.

In soils derived from limestones such as occupy a large proportion of central and south-eastern England, the percentage of this material present is likely to be very high, but in general it does not exceed about 1–2 per cent., and may be even less. The quicklime which is so frequently put upon land is limestone which has been burned to drive off the carbon dioxide gas; but it will quickly absorb moisture and carbon dioxide and become again of the same chemical composition as limestone. An important reason why quicklime or burnt lime is used, is that it breaks up into an extremely fine state of division, and so becomes intimately mixed with the soil, whereas it would be very costly to powder limestone so finely. As a constituent of the soil it is useful, on account of its chemical reaction with farmyard manure, releasing the valuable ingredients and also promoting the formation of nitrates in the soil. It also acts physically upon a soil rich in clay particles, rendering the soil more friable.

Humus.—The presence of humus in the soil is shown by the dark colour which it imparts to the surface soil as compared with the subsoil. It consists chiefly of decaying vegetable matter. Since it is a product of bacterial action carried on in the absence of air, we find more humus in a clayey soil than in an open sandy soil to which air has access. The presence of limestone also prevents to some extent the formation of humus, since it combines chemically with the acids which largely compose the humus, and so prevents the further action of the bacteria. Although humus is not capable of serving directly as a plant-food, it is most valuable on account of its power of rendering the all-important nitrogen available for plant-food. The amount of humus

present in cultivated soils is usually between 2 and 12 per cent. Sandy soils are the poorest and clayey soils the richest. Since humus is such a valuable constituent, the greater the amount present within the limits stated the more fertile the soil. If, however, too great a quantity be present, the soil is likely to become damp and cold on account of the power it has of absorbing and retaining moisture.

Soil Testing.—In order that improvements of soils may be carried out properly, it is necessary to know their constitution, and to accomplish this an analysis or a series of cropping experiments must be made. A complete analysis is a long and laborious work, requiring costly apparatus and practised skill, but everyone may gain a working idea of the relative amounts of sand and clay particles in the following way: A small known weight of dried soil, say about 2–4 oz., should be taken and thoroughly broken up (preferably by boiling and not by hammering or pounding) in a pint of water until all the particles are separated as much as may be. After shaking and allowing to settle for a minute or so in order that all the heavier sand particles can fall to the bottom, pour off the water, which will contain the floating clay and vegetable particles, into another vessel. The point at which the water should be poured off may be found by watching the operation in a glass vessel, and noting when the small shining flakes of mica begin to reach the bottom. The clay particles will take much longer to settle than the sand particles, and so the second vessel should be allowed to stand at least one hour, and then the water very carefully poured off, taking care not to disturb the clayey material at the bottom. Dry and weigh the sand and clay separately, and from these three weighings the proportions of sand and clay can be roughly found.

It will be interesting to examine the sand and clay so separated by means of a hand lens or, better still, a microscope. The sand will be seen to be made up of particles which vary much in size, colour, and degree of rounding which they possess. The quartz grains are usually easily distinguished by their clear, vitreous appearance. The felspar shows a dull, earthy surface due to the decomposition of the mineral. Coloured grains of iron oxide are usually present; indeed, the colour of soils is more frequently due to this mineral than any other. Fragments of sandstone and other rocks as well as some of the large flat flakes of mica can generally be seen. In particular districts other minerals will be very abundant, such as glauconite in the soils derived from the greensands of the south-east of England. The material separated as clay will be seen to consist of particles and flakes of mica, and the other minerals named above, in an extremely fine state of division, as well as much material undeterminable on account of its fineness.

To find out whether the soil contains calcium carbonate or limestone, a little should be dried and rubbed down to a powder in a glass vessel. Then pour a little dilute hydrochloric acid or spirits of salts upon it, and note if there be any effervescence. If very much calcium carbonate be present, the liquid will froth up, but if only a minute quantity is present, the effervescence may hardly be noticed by the eye, but may be detected by placing the ear over the top of the vessel, the bursting of the small bubbles giving a slight hissing

sound.[1] If there be a noticeable effervescence the soil will contain sufficient lime, otherwise a dressing of quicklime for a heavy soil, and chalk for a light soil, should be applied without delay.

The humus may be estimated roughly by taking a known weight of dry soil and heating it to redness for some time on an iron plate (the homely fire shovel will do quite well), and noting the loss of weight. A soil having the following composition is best adapted for general purposes :—

Sand . . .	50–70 per cent.
Clay	20–30 per cent.
Limestone . .	5–10 per cent.
Humus . . .	5–10 per cent.

For further notes on soils, reference should be made to our articles on *Garden Geology*, *Soil Cultivation*, and *Soil Improvement*.

A. G.

SOLANUM (Nightshade.[2] Nat. Ord. Solanaceæ).—The various species of this genus include many classes, such as stove annuals, stove evergreens, shrubs, and hardy annuals. We confine our attention to the greenhouse species and the better known perennial species in the present article, naming, in closing, a few of those which are quite unsuitable, to avoid gardeners making mistakes in selecting species.

Greenhouse Species.—These are most useful subjects for the decoration of cool houses or conservatories. They are best propagated by cuttings (except *S. Wendlandii*, which is best increased by cutting well-ripened previous year's wood into lengths with one or two eyes similar to the Vine) inserted under bell-glasses or frames in sandy soil, and in gentle heat *after flowering*. A suitable soil is a mixture of equal parts good fibry loam and peat, with a good dash of sand. Temperature needed, 45–50° F., except for *S. Wendlandii*, which likes about 65–70° F.

Solanum hybridum.—This has greenish-white flowers from June to October, followed by highly ornamental red berries. Height, 1–2 ft.

S. jasminoides.—This is a good pillar or pot plant, with white, slightly tinted flowers in August. Height, 2–6 ft.

S. Melongena.—See Egg Plant in article on *Salad Plants*.

S. Wendlandii.—This is a splendid pillar or pot plant, with large clusters of lilac-blue flowers from July to August. Height, 2–15 ft.

Hardy Perennial Species.—Some of these are very useful border plants, though, of course, highly poisonous. They may be grown in the ordinary way for hardy perennial plants, and are best propagated by division of the roots in March, at which period they may be successfully planted. We recommend the following :—

Solanum etuberosum.—This bears purplish flowers from June to July, and grows 1½ ft. in height.

S. Maglia.—This is a useful white-flowered species blooming in July, and growing 1–2 ft. in height.

S. Torreyi.—This is a purple sort blooming throughout the summer, and growing about 2 ft. in height.

Undesirable Species.—In this section we include a few of the species it is advisable not to grow in the flower garden.

Solanum Dulcamara.—This is the well-known climber Bitter-sweet, bearing purple flowers from June

[1] This action will not take place with freshly burnt lime, as heat has already accomplished that which the acid does in the above-mentioned experiment, namely, it has driven off the carbon dioxide from the limestone.

[2] This name, Nightshade, is often imagined to be synonymous with Deadly Nightshade. This is not the case, as the latter belongs to the genus *Atropa*, which see.—Editor.

to September, followed by red berries which are intensely poisonous. It grows up to 8 ft. in height.

S. nigrum.—This is a comparatively well-known annual weed which is very poisonous. It produces white flowers from June to August, followed by black berries, and grows up to 1 yd. in height. The HOUND BERRY and WONDER BERRY are forms of it (See also BLACK NIGHTSHADE in article on *WEEDS*.)

S. tuberosum.—This, the humble POTATO, although grown in flower gardens during the Great War, should be relegated to the kitchen garden. Its culture, etc., are fully described in our article on *POTATO*.

See also *CLIMBING AND TRAILING PLANTS*.

SOLDANELLA (MOON-WORT. Nat. Ord. Primulaceæ).—A small genus of hardy alpine plants suitable for the moister parts of the rock garden. They are easily propagated by division in the autumn.

What to Grow.—Only three species need be troubled about, and are briefly described below :—

Soldanella alpina. — Tufts of rounded leaves. Flowers violet coloured, fringed and drooping. Site half-shade. Soil boggy peat. Flowering Period, May to June. Height, 3 ins.

S. montana.—Larger foliage than *S. alpina*. Flowers nearly blue. Site half-shade. Soil boggy peat. Flowering Period, May to June. Height, 4 ins.

S. pusilla. — Tufts of kidney-shaped leaves. Flowers violet or white bells, deeply toothed. Site half-shade. Soil boggy peat. Flowering Period, April. Height, 3 ins.—W. I.

[The Kew authorities call the genus Soldanella the BLUE MOON-WORT.—EDITOR.]

SOLDER.—See *LEAD COMPOUNDS*.

SOLID MEASUREMENT.—See under MISCELLANEOUS MEASURES in *WEIGHTS AND MEASURES*.

SOLIDAGO (GOLDEN ROD. Nat. Ord. Compositæ).—There are a great many better plants than this, but we should get into trouble with old-fashioned gardeners were we to omit it. For the wild garden, mixed border, and shrub border in sun or light shade it is useful, and it may be used for cutting.

Culture.—The Golden Rod can be grown in any ordinary soil with great ease by anyone who cares to plant it in November or February. It may also easily be raised from seed sown at the usual time in the usual way described in the article on *PERENNIALS : GENERAL CULTURE OF*, or by division of the roots in the autumn or spring. Being somewhat of a tall plant, its correct placing should be carefully attended to, and it is essential that it be securely staked early in the season, or it will fall over and become a hopeless mass of twisted stems.

What to Grow.—Any of the following may be successfully grown outside :—

Solidago canadense.—This is a favourite yellow flowering sort coming into bloom in the late summer (August), and continuing for five or six weeks. It grows about 2 yds. high and sometimes more.

S. Drummondii.—A yellow flowering sort coming in from July onwards. Height about 1 yd.

S. lanceolata.—A useful yellow autumn flowering sort opening in September, but at its best in October. Height about 2 yds.

S. serotina.—A late yellow flowering sort, at its best in October, which grows about 2 yds. high.

S. Shortii.—A very useful sort, with a lengthy flowering period commencing in August, and lasting

for about three months. Height nearly 2 yds.

S. Virgaurea.—This is not as good as some of the above. It is a yellow, dwarf-growing sort about 1 yd. in height, and flowers fairly freely in August and September. The variety *cambrica* is about 1 ft. high.

SOLOMON'S SEAL (*Polygonatum.* Nat. Ord. Liliaceæ).—No garden should be considered complete without its groups of the common SOLOMON'S SEAL (*Polygonatum officinale* or *P. vulgare*). It is one of those plants which, wherever it is seen, brings back old associations of those delightful gardens where childhood was spent long ago.

For beginners the various forms of Solomon's Seal described below will prove attractive and highly accommodating subjects. They will practically grow themselves, and do well whatever treatment is bestowed upon them, and thrive luxuriantly however incorrect or haphazard this treatment may be. They do not much mind what their site is; this may be in the open sun or in the shade; nor are they particular as to soil, provided it is moderately rich and not too wet. As regards locality they seem to scorn this entirely, for they grow with quite as great profusion in town gardens as away in the heart of the country. Propagation can be effected by summer-sown seeds or spring division of the roots—the latter for preference—and planting may be successfully carried out any time between November and March.

It is a pity to stick too slavishly to the old variety of common SOLOMON'S SEAL (*P. officinale* or *P. vulgare*), for although it produces pretty drooping white flowers from June onwards, there are better species. These include *P. latifolium* and its variety *commutatum*, as well as such sorts as *P. multiflorum*, better known, perhaps, by the popular name of DAVID'S HARP, *P. polyanthemum*, *P. roseum*, and *P. sibiricum*. With the exception of *P. roseum*, which bears pink flowers in May, all are white-flowered and bloom from May to July. Their height averages 1½–4 ft. The berries of all of them are distinctly poisonous.

SOLOMON'S SEAL: FALSE.— See *FALSE SOLOMON'S SEAL.*

SOMERA.—Now included in the genus *SCILLA.*

SONCHUS (SOW-THISTLE. Nat. Ord. Compositæ).—Here is another genus for unwary amateurs to avoid. *S. oleraceus*, the most general species, the COMMON SOW-THISTLE or HARE'S LETTUCE, is a troublesome weed in many districts. A means of control will be found for it with a short description under the former name in our article on *WEEDS.*

SOOT.—See *SOIL FUMIGATING.*

SOOTY BLOTCH, SOOTY MOULDS.— See *DISEASES OF PLANTS.*

SOPHORA.—For the best species see *SHRUBS* and *TREES.*

SOPHROCATTLEYA, SOPHROLÆLIA, SOPHROLÆLIOCATTLEYA, and SOPHRONITIS. — See *ORCHIDS.*

SORCERESS.—See HARMFUL FUNGI in *FUNGI: EDIBLE AND HARMFUL.*

SORGHUM (MILLET GRASS. Nat. Ord. Gramineæ).—This is a genus of half-hardy grasses hardly worthy of the greenhouse culture required in this country. *S. vulgare*, known respectively by the names of DARI, DURRA, and GUINEA CORN, is the best species, and grows about 4 ft. in height. The genus is distinct from *MILIUM* (which see), also known as MILLET GRASS.

SORREL (*Rumex Acetosa* and *R. scutatus*. Nat. Ord. Polygonaceæ).—The broad leaves of the cultivated form of this plant make a decided acquisition to mixed salad, and are much appreciated by our French friends but too little known at home. Possibly with the wider appreciation of vegetables will come a fuller recognition of the value of salads; then we may expect to see a small patch devoted to this plant in every kitchen garden of importance.

Culture.—Although Sorrel may be found growing very luxuriantly in a wild state upon soils of almost all descriptions, it will well repay those who set out to get the best results from a patch in the home garden to give this something beyond ordinary cultivation. A well dug and heavily manured soil favours the production of large fleshy leaves, scarcely recognisable by those who grow the plant without care in any out-of-the-way corner.

The seed, which may be obtained from any of our best known seedsmen, may be sown any time from the end of March until June. The distance between the drills should not be less than 12 ins. These drills need not be very deep, just sufficient to cover the tiny seed being ample. Thin sowing should be practised in order that the plants may have as little disturbance at the root as possible.

About 10–12 ins. should be allowed between the plants, although half this distance will suffice during the early stages of growth; the surplus, if pulled young, provide very acceptable salad material, or are useful for flavouring purposes.

In early spring give the bed a good mulch of manure or frequent soakings with liquid manure, such treatment being followed by leaves of extra large size. To maintain a good supply of these large leaves, new beds should be formed every two years.—F. R. C.

SOUR SOILS : IMPROVING.—See *SOIL IMPROVEMENT*.

SOUTHERNWOOD.—The genus ARTEMISIA and *A. Abrotanum*. See *ARTEMISIA*, *MEDICINAL HERBS*, and *SHRUBS*.

SOWBREAD.—A name applied to the genus *CYCLAMEN*, which see.

SOWBUGS.—See under WOODLICE in *INSECT PESTS*.

SOWING.—See *SEED SOWING* and *TREES : RAISING FROM SEED*.

SOWING SWEET PEAS.—See *SWEET PEAS*.

SOWTHISTLE, or SOW-THISTLE.—See *SONCHUS*. See also under COMMON SOWTHISTLE in *WEEDS*.

SPADES.—See *GARDEN TOOLS*.

SPANISH BROOM.—The genus SPARTIUM. See *SHRUBS*.

SPANISH CHESTNUT.—The genus CASTANEA, which see in *TREES*. See also *Castanea sativa* in *NUT CULTURE*.

SPANISH FIR (*Abies Pinsapo*).—See *TREES*.

SPANISH GORSE (*Genista hispanica*). See *SHRUBS*.

SPANISH KALE (*Crambe hispanica*). See *CRAMBE*.

SPANISH NUT.—See under COBNUT, FILBERT, AND HAZEL in *NUT CULTURE*.

SPANISH OAK (*Quercus cuneata*).—See *TREES*.

SPANISH SAVIN (*Juniperus Sabina tamariscifolia*).—See *TREES*.

SPANISH SQUILL (*Scilla hispanica*).—See *SCILLA*.

SPARAXIS (Nat. Ord. Iridaceæ). This is a very bright and gay-flowered genus from South Africa. Unfortunately it is only half-hardy in most places in the British Isles, hence the different varieties should be grown in pots. Only in very favoured places may it be grown out of doors, and then it needs protection in the winter. The flowers most frequently seen are

those of various-coloured hybrids raised from *Sparaxis grandiflora*, *S. tricolor*, and *S. versicolor*. They bloom in April, May, and October.

Culture.—Bulbs should be potted in September or October, and then placed in a darkened cold frame, being given light when growth begins. The plants must be protected from frost. Five or six bulbs look well in a 5-inch pot. Very little water must be given until the pots are full of roots and top growth is commencing. *Sparaxis pulcherrima* (Syn. *Dierama pulcherrima*) is totally different from all the other varieties and species. It is not very hardy except in dry, warm positions in the south and south-west of England, although in one case it has been proved to be hardy as far north as Kirkcudbrightshire. The number of beautiful hybrids now offered in dealers' lists is considerable. These flower in August and September.

Species and Varieties :—*Sparaxis Fire King*.—This bears fiery scarlet flowers, with yellow centre, in May. Height, 1 ft.

S. grandiflora.—This bears purple flowers in late April, but there is a white and a parti-coloured variety as well. Height, 1–2 ft.

S. pulcherrima (Syn. *Dierama pulcherrima*[1]).—A very tall slender-looking variety with wiry stems from which hang small pendulous rosy-purple flowers. Although proved to be hardy as far north as Kirkcudbrightshire it does best in a warm situation out of doors, and is useful for cutting. It blooms in October and grows 4–6 ft. in height.

S. Scarlet Gem.—This is one of the best of the hybrid forms, with beautiful brilliant scarlet flowers opening in May. Height, 6–9 ins.

S. tricolor.—The flowers of this are usually orange, or some shade of yellow, and open in May. Height, 12–18 ins.

There are generally a good many varieties listed in the autumn bulb catalogues. These should be consulted as the nomenclature seems to be uncertain.—J. J. & E. T. E.

[1] We retain the old name here as it is far better known than the new one. —EDITOR.

NEW VARIETY.

Sparaxis King George V.—This bears large crimson-maroon flowers, which are yellow at the base. It is of vigorous habit, and is suitable for warm borders, rock garden, or pot culture.

SPARMANNIA (AFRICAN HEMP. Nat. Ord. Tiliaceæ).—This is a very free-flowering greenhouse evergreen shrub, which is propagated by cuttings of young half-ripened shoots in April, inserted in a frame or hand-light with slight bottom heat. A good turfy loam, peat, and sand is a suitable compost. Temperature required, 40–50° F.

Greenhouse Species.—*Sparmannia africana*.—White. Flowers in May. Height, 1½–2½ ft.

S. a. flore pleno.—Double white. Flowers in May. Height, 1½–2½ ft.

SPARTINA (PRAIRIE GRASS. Nat. Ord. Gramineæ).—This is a genus of hardy perennial grasses of little value for the garden, though at times grown in the wild garden. *S. polystachya* (Syns. *S. cynosuroides* and *S. Schreberi*) is the REED GRASS, while *S. stricta* is the CORD GRASS. Both thrive in any soil, the first attaining a height of nearly 2 yds., while the second only reaches half that height.

SPARTIUM.—For the best species see *SHRUBS*.

SPATHOGLOTTIS.—See *ORCHIDS*.

SPATHULARIA.—Now included in the genus *SAXIFRAGA*.

SPATLUM.—See *LEWISIA*.

SPEAR GRASS.—See *ACIPHYLLA*.

SPEARMINT, or SPEAR MINT.—See *MENTHA* and *POTHERBS*.

SPEARWORT (*Ranunculus Lingua*).—See note at end of article on *RANUNCULUS*.

SPECIAL MANURES.—See *MANURES*.

SPECIES AND HYBRIDS OF CROCUSES.— See under SPECIES AND VARIETIES in *CROCUS*.

SPECKLED ALDER (*Alnus incana*).—See *TREES*.

SPECULARIA.—See *VENUS'S LOOKING-GLASS*.

SPEEDWELL.—See *VERONICA*. See also the genus VERONICA in *SHRUBS*.

SPENT HOPS.

These are often available in large quantities from breweries, and may be made use of as manure for the garden. In their fresh state they are not of much manurial value, but if stacked in a heap for about six months and frequently soaked with urine or liquid manure, they will prove when dug in to be of immense value, especially on light soils. They should be used at the rate of about 4 cwt. per sq. rod.

SPERGELLA.—Now included in the genus *SAGINA*.

SPHAEROSPORA.—Now included in the genus *GLADIOLUS*.

SPHAGNUM MOSS.—This is referred to in our articles on *MOSS* and *ORCHIDS: POTTING AND WATERING OF*.

SPIDERWORT.—A name applied to *TRADESCANTIA*, which see.

SPIGNEL.—See *MEUM*.

SPIKE RUSH.—See *ELEOCHARIS*.

SPIKED CORYLOPSIS (*Corylopsis spicata*).—See *CLIMBING AND TRAILING PLANTS*.

SPIKED RAMPION (*Phyteuma spicatum*).—See *HORNED RAMPION*.

SPIKENARD (*Nardostachys Jatamansi*. Nat. Ord. Valerianaceæ).—This may be grown in the rock garden or rock border in light soil without much difficulty. It bears pink flowers from July to August, and grows 18–24 ins. high. It must be carefully distinguished from PLOUGHMAN'S SPIKENARD (*Inula Conyza*), a wild plant or weed of no garden value.

SPIKENARD: FALSE (*Smilacina racemosa*).—See *FALSE SOLOMON'S SEAL*.

SPIKENARD: PLOUGHMAN'S (*Inula Conyza*).—A wild plant of no garden value.

SPILONOTA.—See under ROSE GRUBS in *INSECT PESTS*.

SPINACH (*Spinacia oleracea*. Nat. Ord. Chenopodiaceæ). — Among profitable crops requiring only a short time to attain useful size, Spinach is entitled to a foremost place.

Culture.—A good deep loam enriched with a liberal amount of manure ensures a continuous supply of fresh leaves over quite a long period; but where the bed of soil is shallow, or of a light sandy nature, the sowings made for summer gathering often suffer considerably from drought, and for this reason, where such soil exists and spinach is highly valued, sowing on the little and often principle is recommended in preference to the two or three larger sowings usually found to be sufficient where the plants enjoy a deep and rich soil.

Two varieties are in general cultivation, one having round, the other prickly seed, the produce from either sowing showing little if any difference when cooked.

The Prickly variety is claimed to be the most hardy, and for this reason is usually recommended for autumn sowing; but in light soils we have found the Round to be

equally dependable for winter and summer use.

A small sowing may be made in a warm border early in March, selecting a spot where the crop will be sheltered from cold winds, these retarding growth equally as much as frost. Sow in drills about 12–15 ins. apart, and not less than 2 ins. deep. On good soil each plant should have a clear space of 1 ft. in the row, but where the soil is poor and little manure added 8 ins. will be ample.

The earliest sowings often run to seed quite early in the season, particularly if a dry period follows germination. This risk will be considerably minimised if the hoe is used frequently between the rows.

Picking may commence as soon as the leaves are the size of a crown-piece, care being taken to do it without disturbing the roots, always confining attention to one row at a time. If this is done there will be no waste of leaves, but a constant supply always coming on.—F. R. C.

SPINACH BEET.—See *PERPETUAL SPINACH.*

SPINACH: NEW ZEALAND (*Tetragonia expansa.* Nat. Ord. Aizoaceæ).—This is quite distinct from the two other varieties. It requires to be sown one seed in a small pot in a greenhouse during April, and kept well supplied with water until the end of May, when a good sunny position should be chosen, and the plants put out at not less than 30 ins. between the rows and 2 ft. between the plants. If well supplied with water, plants at this distance will cover all the ground between them in a very short time, and continue to give crops of large fleshy leaves until destroyed by frost. Readers having a hot dry soil where the ordinary spinach rarely gives satisfaction, may safely plant this and have no fear regarding the result.—F. R. C.

[This vegetable does not prove digestible to some people.—EDITOR.]

SPINACH: PERPETUAL.—See *PERPETUAL SPINACH.*

SPINACIA.—See *SPINACH.*

SPINDLE-TREE.—The genus EUONYMUS and *E. europaeus.* See *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

SPIRAEA (Nat. Ord. Rosaceæ).

This genus is a large one, but it is beyond our scope to describe anything like all the species which are known. Many species are shrubby, and some of these are included in our list of Shrubs (see article on *SHRUBS*). Those we describe below are hardy tuberous perennials or hardy herbaceous perennials, suitable for herbaceous or mixed borders. All are closely allied to the genus *ASTILBE* (which see), and when any re-classification is done the two genera will probably be united.

Culture of these plants is a simple matter. They are fond of cool damp spots in light but rich soil, and are excellent subjects for shady borders or under light shade of trees. If grown in full sun plenty of water must be afforded them throughout the summer. A mulch of very old manure or leaf-mould in the early winter is greatly to their liking, and free cutting of the flowers will increase the length of the blooming period. As regards propagation this is quite a simple matter, and is best effected by division of the roots in February or March, which months are also the best periods for planting. We recommend the following:—

Spiraea Aruncus (GOAT'S BEARD).—This is one of the well-known sorts bearing white flowers in June and July, and growing 3–4 ft. high.

S. astilboides.—This is a white July blooming sort about 1½ ft. high.

S. decumbens (Syn. *S. procumbens*).—This is a good species for the rock garden, bearing white flowers from June to August, and growing about 12 ins. high.

S. digitata.—This bears attractive red flowers in July, and may grow up to 1 yd. in height.

S. Filipendula (DROPWORT).—This white tuberous-rooted perennial bears its bloom in September, and grows about 2 ft. high.

S. japonica.—Syn. *Astilbe japonica*, which see.

S. lobata.—This bears red flowers from July onwards, and grows about 1½–2 ft. in height.

S. palmata.—This is a synonym of *S. digitata* according to some authorities, but is recognised as a distinct species at Kew. It bears dark red flowers from July to August, on plants about 1½ ft. high. Its variety *alba* is white.

S. procumbens.—Syn. *S. decumbens* above.

S. Ulmaria.—This, the common MEADOW SWEET, is not worthy of border culture, but is highly useful in the wild garden, where its white flowers are produced freely in July and August, on plants 2–3 ft. high.

SPIRE REED (*Phragmites communis*). See *PHRAGMITES.*

SPIRITS OF SALTS.—A popular name of HYDROCHLORIC ACID, which see in *ACIDS: THEIR USES IN HORTICULTURE.*

SPOTTED ORCHIS (*Orchis maculata*). See *HARDY ORCHIDS.*

SPRAY YOUR POTATOES. — The reasons for urging this will be found in the article on *POTATO BLIGHT.*

SPRAYING FRUIT TREES. — See *FRUIT TREES: SPRAYING.*

SPRAYING MIXTURES AND FUNGICIDES.—Of chemical substances which are poisonous to fungi and act as "fungicides," the two most important are copper and sulphur, and most of the fungicides in common use depend for their killing action upon one or the other.

Fungicides are used as liquid spraying mixtures, dry powders, steeping solutions, and washes. In a general way spraying mixtures have proved more efficacious for the majority of diseases in England, though powders are preferable in a few cases. Steeps are used for disinfecting bulbs, potato tubers, seeds, etc., and the same solutions, made a little stronger, may be employed for sterilising bags, boxes, floors, walls, etc. Of patent mixtures some are good and some bad, but it is obvious that in the present work none can be singled out for praise or censure. The chemical mixtures and solutions recommended below have proved their value as thoroughly good fungicides. With regard to Burgundy Mixture, if pure chemicals are used, such an excellent mixture can be prepared with comparatively little trouble, that the fresh home-made article is to be recommended. Bordeaux Mixture is slightly more difficult to make; but here again the home-made article gives first rate results, which cannot always be said of ready-made proprietary preparations.

Bordeaux Mixture.—For Bordeaux Mixture lime is used instead of the usual soda, and it will be convenient to take the same sized vessels for mixing as for Burgundy Mixture below. Freshly burnt quicklime of the best possible quality in lump form should be obtained, and the copper sulphate should be of fully 98 per cent. purity. The amounts required for potato spraying are 4 lb. copper sulphate and 2 lb. lime (for fruit, see next paragraph). The copper sulphate should be dissolved in 5 gallons of water in the large tub, and 30 gallons of water added. In the

smaller vessel 2 lb. of lime should be slowly slaked with a little water, gradually adding water until the whole becomes a thick cream, which should then be diluted with water to make 5 gallons. This must be thoroughly stirred, and strained through a fine wire sieve if necessary. When required for use the two solutions should be mixed by slowly adding the lime-water to the 35 gallons of copper sulphate, the whole mixture being vigorously stirred during the process. If the mixture has been rightly prepared it should have a flocculent precipitate that remains in suspension, and the whole 40 gallons should be uniform, no clear fluid separating out. It must be used as soon as possible, and will not keep good more than twelve hours.

FOR FRUIT-TREE SPRAYING.—The preceding mixture is primarily for potato spraying. For fruit trees slightly different proportions are now generally used. Copper sulphate 4 lb., best burnt lime 4 lb., and water 50 gallons. It is used for Apple Scab, Pear Scab, and Vine Mildew, and further details will be found under these headings in our articles on *APPLE DISEASES* and *DISEASES OF PLANTS*. Burgundy Mixture is not considered suitable for fruit trees.

Burgundy Mixture.—This is used almost exclusively for potato spraying. For mixing Burgundy Mixture a 40-gallon paraffin barrel is a convenient size, and another smaller vessel, holding at least 5 gallons, will be required. On no account must an iron or zinc vessel be used for holding the copper sulphate used in this or in Bordeaux Mixture. Forty gallons will spray about 50 rods. The mixture now recommended is that known as 1 per cent., for which purpose 4 lb. of pure copper sulphate (which should again be obtained with a guarantee of 98 per cent. purity) and 5 lb. of pure washing soda will be required. If a smaller quantity of mixture be desired, it is easy to make a calculation based on the above figures. The solution should be prepared early in the day, as it deteriorates rapidly and must be used at once, and certainly not more than twelve hours after mixing. The method of mixing is as follows :—

First dissolve the 4 lb. of copper sulphate in 5 gallons of water in the large tub; if the copper sulphate is in crystal form it should be crushed first. When dissolved, add 30 gallons more water and stir. Next dissolve the 5 lb. of washing soda in 5 gallons of water in the smaller vessel; the more finely broken up the soda is the quicker it will dissolve. When it is completely dissolved the two solutions may be mixed. The soda solution should be slowly poured into the 35 gallons of copper sulphate, stirring the whole thoroughly meanwhile. The resulting mixture should be a brilliant blue, and with a fine precipitate which should remain in suspension for some time. As the sulphate of copper is poisonous, some care should be exercised, and the tubs should be well rinsed out after use.

A good knapsack sprayer may be used for spraying in quite small gardens; for greater areas there are many larger and efficient machines. The important point is to cover the foliage with the mixture both on the upper and the under surfaces. A fine mist is the ideal state in which the spray should be applied; if too much is given the mixture rolls off and the leaf surface is not properly covered. See also article on *POTATO BLIGHT*.

Lime Sulphur.—This is an excellent spray for mildews (notably American Gooseberry Mildew), and is also useful for Apple Scab and

other diseases. It has the advantage of being easily prepared, since very good brands of concentrated lime sulphur can now be purchased in large or small drums, and all that is necessary is to add the appropriate amount of water. A guarantee of 1·3 specific gravity should, however, be obtained when ordering. As sulphur reacts with copper, care must be taken that machines with copper parts are not used for lime sulphur spraying. For ordinary summer use the strength required is 1 part in 30 (*i.e.* 1 gallon of the concentrated solution to 29 gallons of water, or 3 pints to 10 gallons). The concentrated lime sulphur should be poured slowly into the water, well stirred, and used the same day. In the case of a few varieties of apples, notably *Cox's Orange Pippin*, and gooseberries (see under GOOSEBERRY MILDEW (AMERICAN) in article on *DISEASES OF PLANTS*), scorching occurs at the above strength; hence the half summer-strength solution should be used (*i.e.* ½ gallon of concentrated lime sulphur to 29 gallons of water, or 1½ pints to 10 gallons).

Potassium Sulphide (or *Liver of Sulphur*). — This substance was formerly used extensively either as a simple solution or with the addition of other substances. Owing to war conditions it has, however, become scarce, and growers have resorted more to lime sulphur. Potassium sulphide is specially useful for indoor work or in the case of ornamental plants, where a white covering of Bordeaux Mixture would be objectionable, and it is advised also in the case of indoor fruit. The usual strength recommended is 3–5 oz. of potassium sulphide to 10 gallons of water, the exact proportions depending on the nature of the plant and on the hardness of the foliage. As a rule, however, the simple solution of potassium sulphide in water does not posesss sufficient wetting power, and for this reason the addition of a small quantity of soft soap (1½–2 lb. to the 10 gallons, depending on the hardness of the water) is advisable. Such a mixture is undoubtedly effective for many mildews, but in the case of American Gooseberry Mildew, the summer stage of which is particularly "powdery," the further addition of paraffin (1½ pints to the 10 gallons of spraying solution) has proved necessary to destroy it effectively. It is necessary, however, to be very cautious when using paraffin sprays.

Powders for Dusting.—Dry powders are successful in combating certain diseases, especially mildews. Flour of sulphur, or better still some of the very finely precipitated forms of sulphur, including green and black, are the most useful. These powders should be applied by means of a sulphurator or special bellows, or any home-made apparatus that will distribute the powder in a fine and even manner. Powders are particularly useful for Onion Mildew, Peach Mildew, Rose Mildew, Strawberry Mildew, and Tomato "Rust," and should be applied early in the morning, when the plants are wet with dew. They are more effective in warm dry weather than when wet and dull.

Soil Fungicides.—Though several substances, such as bleaching powder, carbolic acid, and copper sulphate, are powerful fungicides, a good method of thoroughly disinfecting the soil with chemicals is badly needed. One of the greatest difficulties is, that it is practically impossible to distribute the substance thoroughly and evenly through any bulk of soil without giving some part too much, and thus poisoning it as a whole. So far the most satisfactory method is sterilisation by steam, for which purpose several forms of apparatus

are now on the market; but this is obviously only suitable for work on a small scale or glasshouse use. In a general way fungous diseases at the root are more prevalent in soils lacking lime; liming therefore, though by no means sufficient to kill fungus spores, should not be neglected.

Steeps.—Steeping solutions used for sterilising seed tubers, etc., are generally prepared from copper sulphate or formaline. The former, though extensively used by the farmer, is not often required by the horticulturist, but a 2 per cent. wash of copper sulphate is useful for disinfecting bags, boxes, floors, etc., suspected of being infected with fungus spores. Formaline, however, is more effective, though more dangerous to handle. The greatest care must be exercised and only weak solutions employed. For steeping seed potatoes contaminated with spores of ordinary scab or corky scab, ½ pint of formaline in 15 gallons of water is sufficient strength, and the tubers should be steeped for three hours in the solution. The same strength is useful for disinfecting floors, etc.—A. D. C.

SPRING GARDEN, THE.

The spring in the garden is really the time of re-birth of plant life, and although botanists may prove to us that the re-start is made in the autumn, the fact is not sufficiently evident to convince gardeners of its truth. Certainly the spring is one of the most beautiful times in the garden, though not so beautiful as summer; but the freshness of everything, the new zest for life of every tree and plant, and the colour of the first flowers make spring alike a beautiful and happy time. As the gardener goes round his borders in the early spring he sees everything shooting into new growth, with the increasing sunshine and the lengthening days. Soft succulent shoots push their way through the bare soil, and what was a day or two before nothing but black earth, is now covered with lovely green verdure. The same remark applies to his deciduous climbers. One day there will be nothing but bare stalks, and the next day they are covered with a wealth of green leaves. The spring is also the time for splashes of colour. Borders judiciously planted with bulbs in the autumn may be one day green, and the next day golden; and one day they may be grey, while on the next they are covered with crimson flowers. In the rock garden, too, the evergreen plants may, when one looks at them, be a silvery-green, on which the winter rain and frost have played, and a little later be covered with all the colours of the rainbow.

Certainly the spring is one of the gardener's happiest periods. He cannot help being stimulated to new exertions, and new experiments, if he watches his flowers shooting up as he works amongst them. There is something invigorating also about the beautiful scents of the spring flowers, the soft winds and sunny days, and even the April showers.

Work in Spring.—We must not, however, take up all our space with describing the wonders of spring, for this Dictionary is to be a practical

work first of all, so we pass on to mention a few of the many jobs that must be done at this season, and the first job we must carry out before any others, is to hoe thoroughly, and loosen the soil among our quick-growing herbaceous plants. Weeds, of course, spring up quite as quickly as other plants, and unless our borders are to be glorious with the colour of Dandelions, matted with the growth of Crowfoot weed, and carpeted with a covering of Daisies, it will be necessary for us to bring our hoe out and to work it very hard. A good thing to do is to follow the hoeing with a thorough raking, and then we can remove from the borders surplus stones which have worked up during the last winter. Another job of great importance is the planting of bare spaces in our borders to make good the fatalities of the previous winter. Jack Frost will take his due, and he deserves it for the good he does, but when he robs us of the choicest specimen of *Anchusa italica*, our very best Helenium, and the *Polemonium Richardsonii* of which we were so proud, we perhaps feel unkindly disposed towards this useful and benevolent gentleman. So when the spring comes, and before it is many days old, our borders should be carefully gone over, the bare spaces being marked, and suitable subjects planted to fill the gaps which have been made. It would take up too much space to describe the many subjects which can be used, but readers should study the articles on the various plants which will be found in this Dictionary.

Yet another job in the spring is the sowing of Hardy Annuals. There has been somewhat of a prejudice against the free use of Hardy Annuals, but such prejudice is mistaken, as the Hardy Annuals include some of the most lovely of all the plants the gardener grows. The pure simplicity of the Shirley Poppy, with its lovely colours, the glorious spikes of Godetia and Clarkia, the dazzling orange of the Pot Marigold (*Calendula officinalis*), are but a few instances of the beauty of these plants. Early sowing invariably gives good results, and the end of March and the beginning of April are periods which should not be wasted for getting the seeds into the ground. April showers are inseparable from the culture of Hardy Annuals, and if sowing is postponed until early May as so many advise, the plants miss these natural benefits and so suffer greatly in consequence.

There is no doubt that spring is also the time for replenishing the rock garden, and here we must admit that we are unorthodox. Many rock gardeners advise the sowing of all manner of Hardy Annuals in the rock garden during April, but why the rock garden should be taken up with them when most of them do better in the open borders, is a question which fortun ately it is not our task to answer. It seems to us wasted space and wasted effort to sow Hardy Annuals in the rock garden, but there is no reason at all why rock plants of the usual kinds should not be planted, provided that the work is done early in April, and they are looked well after as regards water. Almost all of the Saxifrages, Sedums, and Sempervivums may be successfully planted during this month, and a wealth of other subjects too numerous to mention.

Provided that the work is done in the early spring, there is no reason at all why wall gardens should not be planted, and of these we cannot speak too highly from the point of view of their beauty. We see no

reason why there should be bare, ugly walls, supporting earth in gardens, when there is such a number of plants which will cover these walls. It seems to us whenever we pass such walls that glorious opportunities for colour effects have been wasted, and all garden lovers should be on the look out for new chances of increasing the beauty of their gardens.

Indoor Gardening. — Spring is certainly a busy time in the indoor garden, what with potting of plants, raising suitable subjects for bedding, and so on. There is also the repotting of many subjects to be done, and this operation cannot well be carried out except at a time when the plants are just re-starting into growth. Much care is needed in looking after newly re-potted subjects, since over-watering may soon spell disaster. For this point we will refer the reader to our articles on *Greenhouse: Management of*, and *Watering*.

The gardener should also in the early spring buy in such quantities of fertilisers as he may be likely to require. He should likewise look through his appliances, such as his Potato Spraying Machine, his Mowing Machine, and seal up all the holes in the bottom of his watering-cans. These appliances will all be needed in the early summer, if not before, and to have them ready will save much time later.—E. T. E.

STACHYS (Woundwort. Nat. Ord. Labiatæ).—This genus contains a large number of annual and biennial, hardy and half-hardy evergreen species, all of which are of little interest and are excluded from the present edition of this work. A few of the best of the hardy perennial species for the herbaceous border are described below; these

thrive in ordinary common garden soil, are propagated by seeds sown in the spring or summer, or by division of the roots in the autumn and spring, and may be successfully planted from October to March :—

Stachys affinis (Syn. *S. Sieboldi*).—See article on CHINESE ARTICHOKE.

S. alpina.—This may be planted in the rock garden and bears purplish-red flowers from June onwards. It only grows 1 ft. high.

S. Betonica.—This is the common WOOD BETONY, bearing purple flowers from June to September, and growing about 2 ft. high. It is referred to in our article on *MEDICINAL HERBS.*

S. coccinea.—This is an attractive scarlet July blooming sort needing a warm corner. It grows about 1 yd. high.

S. grandiflora.—This is a large purple-flowered sort blooming in May and June, and growing 1½ ft. high.

S. recta.—This bears yellow flowers in July, and grows about 2 ft. high.

S. Sieboldi (Syns. *S. affinis* and *S. tuberifera*).—See article on CHINESE ARTICHOKE.

S. tuberifera.—Syn. *S. Sieboldi* above.

STACHYS.—This is a synonym for CHINESE ARTICHOKE, which see.

STACHYURUS.—For the best species see SHRUBS.

STAFF TREE (*Celastrus articulatus*). See CLIMBING AND TRAILING PLANTS.

STAGGER-BUSH (*Pieris mariana*).—See SHRUBS.

STAGHORN SUMACH (*Rhus typhina*). See TREES.

STAKES AND STAKING.

It is probable that no one who sets out to tend a garden gives a thought to the part stakes and staking will play in its future successful conduct. The primary thought of all gardening enthusiasts is the soil; but soon there comes a time when, plants having made their appearance, it is seen some support must be given if they are to develop to their best and withstand the weather. The subject of staking is most naturally associated with flowering plants, and it is with this end in view these notes are given, though, incidentally, staking is also necessary in both the fruit and vegetable garden.

Staking : Its Use.—The secret of proper staking is to preserve the natural symmetry of the plants. This is an art requiring considerable practice. Much staking done has the very opposite effect to that of preserving the natural beauty of the plant. Generally it is much too tightly done, giving the subject a "bunched" appearance. Such work is very ugly—the inborn natural grace of the plant being completely destroyed.

Some families of plants can be dwarfed by being pinched in early growth, thus almost obviating the need for staking, and in any case rendering a shorter form of support quite efficient. Examples answering to this treatment are border Chrysanthemums and Michaelmas Asters. Many other hardy flowers can be pinched, and will suggest themselves to the observant enthusiast.

It is better to stake thoroughly than to do the work by halves. Flimsy staking is all too frequent. Plants might just as well be left to fall about on the ground from the first as to loll about between two wobbly stakes, or tied round the waist to one stake, giving an appearance greatly resembling a child's gollywog.

When and How to Stake.—Some say staking should not be done until really necessary. This sounds feasible—it would be eminently

practical, if we could forecast the weather; but a sudden gale may come on, and plants hitherto in the finest condition may be laid flat in all directions through neglecting to stake them. It is better to secure all plants that are expected to want support in an early stage of growth. Such will prevent disaster and save many disappointments. Not all types of plants will need dealing with at one time. Some will need attention sooner than others. Those which suffer most if long delayed are annuals, climbing plants, and such choice genera as Delphiniums and Lilies.

The reasons for this will be obvious: Annuals become straggly in appearance when left unstaked too long, and never wholly regain that first healthy erectness of form; climbers, when staking or training is neglected, become an intertwined mass, and are so easily snapped or broken at the base that no further emphasis should be wanted to show the folly of delaying early support. On the other hand, fortunately, many hardy flowers—perhaps the greater bulk—do not suffer so disastrously if for any reason it is not possible to stake them when one would desire to.

How to Stake.—Closely bound up with when to stake a plant is how it should be done. Briefly, this should be so done that when plants reach perfection the stakes appear an essential part of the plants, and look as unobtrusive as artificial assistance can do. Also, stakes should be so placed in position that their tops lean slightly outwards; this allows more space for the increased growth of stem and foliage natural to all plants nearing full growth. The distance, too, of the stake from the root or crown of a plant should not be lost sight of, the chief point being to avoid driving the support into roots or crowns, especially those of delicate constitution and precious worth.

Kinds of Stakes to Use.—Roughly, stakes can be divided into two groups: branched, and trimmed or straight stakes. (Reference to the wire spiral supports used by some Carnation growers is here purposely omitted.) Both kinds have their value and place of use, but the trimmed stakes are often made to do duty when the untrimmed or spruce stakes ought to have been used. Indeed, one might add, the latter type of stake is practically unknown in very many so-called good class gardens of to-day. Such gardens are the losers; for it is the use of branched stakes only which permit in many plants their free and normal appearance. To be convinced of the enormously increased beauty where branched stakes are used, readers will only need to sow two different beds of each of such annuals as Clarkia and Nigella. One bed of each should be staked with ordinary straight sticks, and the other bed of each with branched or twiggy sticks. Within a few weeks the superior results of the latter will be easily seen.

Among straight stakes high place must be accorded to canes of all sizes; they are handy and durable. Deal stakes too of all sizes are serviceable and much in demand. They should be painted to preserve the wood, a dark green colour being the least obtrusive. But any kind of wood will suit if it be straight and sound, and such material can often be obtained locally.

Branched or untrimmed stakes—familiar examples being the culinary pea and Sweet Pea sticks—are, as we have said, unquestionably the best for preserving the natural habit of

almost every plant; and these can be had or made into any length, while most kinds of brushwood or undergrowth will answer so long as it is not too old. The advantage of this type of support is soon apparent in the enhanced beauty of development encouraged—especially with bushy habited plants such as Delphinium, Gypsophila, Helenium, and Sidalcea. Furthermore, tying is reduced to a minimum, only an occasional tie being necessary.

Annuals, old Carnation roots, and Pinks of all sorts look well done with birch-broom twigs. Single-spiked plants such as the Hollyhock are neater done with a plain straight stake; so, too, are Canterbury Bells as a rule. Dahlias, also, are truly imposing when done with plain stakes—say strong canes, one to each main growth. Four stakes around any ordinary bushy plant, like a Paeony, for instance, will give a result satisfactory to most people. A good rule is, while not over-staking, always to use enough sticks to keep the shape of the plant. Do not strangle a plant to a single stake when several ought to have been used.—C. T.

STAKING SWEET PEAS.—See *SWEET PEAS.*

STANDARD CHERRIES. — See *CHERRIES.*

STANDARD TREES: PRUNING OF.—See *PRUNING FRUIT TREES.*

STANDISH'S HONEYSUCKLE (*Lonicera Standishii*).—See *CLIMBING AND TRAILING PLANTS.*

STANHOPEA.—See *ORCHIDS.*

STAPHYLEA.—For the best species see *SHRUBS.*

STAR-FLOWERED LILY OF THE VALLEY (*Smilacina stellata*).—See *FALSE SOLOMON'S SEAL.*

STAR HYACINTH (*Scilla amoena*).—See *SCILLA.*

STAR OF BETHLEHEM *Ornithogalum.* Nat. Ord. Liliaceæ).—Although the genus Ornithogalum is of considerable extent, not many species are met with in general cultivation. The majority of the species are hardy, but some from South Africa are only half-hardy.

Culture.—The hardy sorts are not particular about soil, though they prefer one on the light side. *Ornithogalum umbellatum* will grow in partial shade, and may be planted in grass. The half-hardy varieties must be grown under glass in a cool greenhouse. They like rich, light soil and should be potted up in September or October, and wintered in a cold frost-proof frame. They may be introduced into mild heat in March.

Species:—*Ornithogalum arabicum.*—A fine plant growing about 2 ft. high and blooming in early summer, or under glass in late spring. It has beautiful pure white flowers with a shining black centre, and a delightful scent. Three large bulbs look well in a 7-inch pot. Unfortunately it is a shy bloomer, and it is best to buy bulbs every year, as they need a warm and sunny summer to get properly ripened. It is only half-hardy in the British Isles.

O. nutans.—This has silvery-white flowers, and blooms in May. Its height is 18 ins. Irregular clumps are effective in borders on account of the distinct colour of the flowers, which are loosely arranged in spikes.

O. pyramidale.—This fine plant produces pure white starry flowers in June. Its height is 1½–2 ft.

O. pyrenaicum.—This, popularly known as BATH ASPARAGUS, is not as lovely as some. It bears greenish flowers from May to June, and grows about 2 ft. high.

O. thyrsoides.—This is a fairly tall yellow-flowered species from South Africa, which blooms in June and

grows about 15 ins. high. It is not hardy, and must be grown in a cool greenhouse.

O. umbellatum.—This, the COMMON STAR OF BETHLEHEM of English gardens, grows anywhere and increases by self-sown seed very quickly. The flowers are pure white and close early in the afternoon. They are borne in May, on plants 6–9 ins. high.—J. J. & E. T. E.

STAR TREFOIL (*Trifolium stellatum*). See *TRIFOLIUM.*

STAR TULIPS.—See *MARIPOSA LILIES, or STAR TULIPS.*

STARCH HYACINTH (*Muscari racemosum*).—See *GRAPE HYACINTHS.*

STARRY DAISY BUSH (*Olearia stellulata*).—See *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

STARWORT.—See *ASTER.*

STATICE.—See *SEA LAVENDER.*

STAUNTONIA.—For best species see *CLIMBING AND TRAILING PLANTS.*

STEEPLE-BUSH (*Spiraea tomentosa*). See *SHRUBS.*

STEEPS.—See *SPRAYING MIXTURES AND FUNGICIDES.*

STEGANIA.—Now included in the genus LOMARIA, for which see *FERNS AND FERN GARDENING.*

STEIRONEMA (Nat. Ord. Primulaceæ).—Three species of this genus, *S. ciliatum, S. heterophyllum,* and *S. longifolium,* were once species of *LYSIMACHIA,* as mentioned in that article, and require similar culture, though they are not very suitable for the rock garden. They are hardy herbaceous perennials bearing yellow blooms from July to August, and growing 2–3 ft. in height.

STEM AND LEAF CROPS.—See under CROP REQUIREMENTS in *MANURES.*

STENACTIS.—Now included in the genus *ERIGERON.*

STENOLOMA.—Now included in the genus DAVALLIA, for which see *FERNS AND FERN GARDENING.*

STEPHANANDRA.—For the best species see *SHRUBS.*

STEPHANITIS.—See RHODODENDRON BUG in *INSECT PESTS.*

STERILISER.—This is used in fruit and vegetable bottling. See *FRUIT BOTTLING AND PRESERVING* and *VEGETABLE BOTTLING.*

STERILISING FRUIT.—See *FRUIT BOTTLING AND PRESERVING.*

STERILISING SOIL. — See *SOIL STERILISATION.*

STERNBERG'S PINK (*Dianthus Sternbergii*).—See *DIANTHUS.*

STERNBERGIA (Nat. Ord. Amaryllidaceæ).—This is a genus of half-hardy bulbs only suitable for outdoor culture in warm localities and very sunny sites. Pot culture in the cool greenhouse is the best way of growing them, and then there is no difficulty whatever. Light sandy loam is the best of soil. Outdoor planting should be done in April, and potting about July.

What to Grow.—We recommend the following, all of which bear yellow flowers from the autumn right into the winter and grow about 6 ins. high: *Sternbergia colchiciflora, S. fischeriana, S. lutea,* the WINTER DAFFODIL, and its varieties *angustifolia* and *Ikariae, S. macrantha,* and *S. sicula. S. lutea angustifolia,* which is the best bloomer, and *S. macrantha* are practically hardy.

STEWING PEARS. — See list of PEARS FOR BAKING AND STEWING in *PEAR.*

"STIFF" FLOWERS.—See *FLOWERS UNSUITABLE FOR CUTTING.*

STIGMA.—See under LIFE HISTORY OF FLOWERING PLANTS in *PLANT PHYSIOLOGY.*

STINGING NETTLE (*Urtica dioica*).—See *URTICA* and *WEEDS.*

STINK LILIES.—Another name for *CROWN IMPERIAL,* which see.

STINKING HELLEBORE (*Helleborus foetidus*).—See *HELLEBORUS.*

STINKING HOREHOUND. — See *BALLOTA.*

STIPA (Feather Grass. Nat. Ord. Gramineæ).—This is a large genus of hardy perennial grasses. The most useful species is *S. pennata*, the Common Feather Grass, referred to in our article on *Ornamental Grasses*. *S. spartea*, popularly known as Porcupine Grass, may become a troublesome weed, and should be carefully spudded out in its early stages.

STOCKS (*Matthiola*. Nat. Ord. Cruciferæ):—**Annual Species.**—Only one of these is worthy of special mention here, on account of its exquisite fragrance during the evening. This, *Matthiola tristis*, the Night Scented Stock,[1] bears dull white flowers throughout the summer, which are quite unattractive in the daytime. These open out in the evening and are borne on plants about 1¼ ft. in height.

Sowings of this species should be made at intervals in the spring and early summer in much the same way as *Mignonette* (see separate article). The site should be carefully chosen so that the perfume of the flowers may be enjoyed when passing along the paths. Thinning out is necessary but must be carefully done. The plants may also be raised and treated as half-hardy annuals.—C. H. C.

Kinds of Stocks.—The following are notes on a few of the best forms of Stocks, varieties being given where possible:—

Bedding Stocks.—For summer flowering the Ten-Weeks Stocks, referred to below, are very favourite for bedding purposes, and next to them come the East Lothian Stocks, also dealt with below. Brompton Stocks and Queen Stocks (see below) are used for spring and early summer bedding but only to a very limited extent.

Brompton Stocks.—These should be sown in May or June for subsequent pricking off or planting out as soon as large enough. They may otherwise be treated in exactly the same manner as the popular East Lothian Stocks referred to below. They are available in pink, purple, scarlet, and white, separately or mixed. The following are the best varieties:—

Old English Scarlet Brompton.—This bears scarlet flowers in May and June, on plants about 2 ft. high.

Sunrise.—This bears flowers varying from coral-red to bright rose. It blooms from May to July, and grows 8–15 ins. high.

Sutton's Carmine Queen.—This bears brilliant carmine flowers in May and June, on plants 18 ins high.

Sutton's Express.—This bears pale rose flowers from May to June, on plants 18 ins. high.

East Lothian Stocks.—These should be sown thinly in boxes in a cold frame in July or August, and pricked off into other boxes as soon as large enough to handle. Later on they should be potted singly into 3-inch pots and wintered in a cold frame or unheated greenhouse. Outdoor planting is best delayed until late March or early April, late April at times proving early enough in very cold Northern districts. Those who live at the coast from Frinton to Peterhead, or indeed farther North, may safely leave established plants outside right through the winter; inland they may survive at the foot of walls in mild winters, but it is better to lift and keep them in frames from November to mid-March to keep the foliage dry. The colour range

[1] *Hesperis tristis*, which forms the subject of our article on *Night Scented Stock*, is a distinct plant and bears purplish, brownish-red, or cream flowers.—Editor.

of these Stocks extends through crimson, lavender, purple, and rose, to scarlet, and there is also a pure white form. The two best varieties are :—

Crimson Wallflower-leaved.—This bears crimson flowers from May to September, and grows 12–15 ins. high.

White Wallflower-leaved. — This bears pure white flowers, but otherwise resembles the one just described.

NIGHT SCENTED STOCK.—See the notes already given on ANNUAL SPECIES.

QUEEN STOCKS.—These may be sown from May to July, and after being duly pricked off should be protected in a cold frame or greenhouse through the winter prior to planting out in April. They are quite easy to grow and very attractive. The colour range extends from crimson and pink to purple and scarlet. There is also a white form. The best varieties are :—

Spring Bedder.—This bears apple-blossom pink flowers in May and June, on plants 12–15 ins. high.

Sutton's Spring Bedding.—This can be had in light blue, scarlet, or white. It flowers in May and June, and grows 12 ins. high.

TEN-WEEK STOCKS.—As already mentioned, these are the most popular for summer bedding. They are easily raised from seeds grown in the usual way for half-hardy annuals in March, and subsequently pricked off and planted out in May. The colour range is very extensive ; in some of the varieties below there are twelve or eighteen different shades. The best varieties are :—

Giant Perfection.—This is available in twelve distinct colour shades, such as blue, carmine-pink, crimson, delicate pink, pale mauve, purple, rose, terra-cotta, yellow, white, etc. It blooms from June to August, and grows 15–18 ins. high.

Improved Dwarf Large-flowered.—This is available in eighteen colours or colour shades, including all those given under the variety just described. It blooms from June to August, and grows 12 ins. high.

Perfection Ten-week.—There are six or more colour variations of this, such as blue, carmine, rich pink, rose, scarlet, yellow, and white. It blooms from June to the end of September, and averages 18 ins. in height.

Superb Bedding.—This is available in nearly a dozen colours or colour forms, such as blush, peach-blossom, rose, scarlet, etc. It blooms from June to August, and grows about 10 ins. high.

WINTER-FLOWERING STOCKS. — These should be sown in May or June, to flower from Christmas onwards ; they may also be sown in June or July, to bloom in the spring and early summer. Frame treatment may be given in the summer, and the plants transferred to the heated greenhouse in early October. The colour range is very extensive as in most other forms of Stocks. We recommend the following :—

All the Year Round.—This bears white flowers, and is a perpetual flowering sort. Height, 1 ft.

Beauty of Nice.—This can be had in crimson, flesh-pink, mauve, old rose, primrose, yellow, or white forms. It blooms in the winter and spring, and grows about 2 ft. high.

Christmas Pink.—This bears pale pink flowers in the winter and spring, on plants 1½ ft. high.

Queen of Mauves.—This bears pale mauve flowers from December onwards, and grows about 1 ft. high.

Riviera Market.—This may be had in white or rose forms. It blooms from Christmas right through the winter, and averages 1½ ft. high.

Yellow Prince.—This bears pale yellow flowers from Christmas onwards through the winter, and grows about 1½ ft. in height.

Rare Species of Stocks.—A few of the most interesting are briefly described below:—

Matthiola bicornis. — This half-hardy and shrubby species bears purplish-red flowers in the spring on branching stems, and grows about 12 ins. high.

M. fenestralis.—This, also half-hardy and shrubby, bears scarlet or purplish flowers on upright, unbranched stems during July and August. Height, 1 ft.

M. odoratissima.—This, which requires greenhouse protection, bears dull creamy flowers which turn to purplish-brown when old. They are produced on somewhat woody branching stems, during June and July, on plants 1–2 ft. high.

M. sinuata.—The flowers of this biennial or perennial species vary from clear to deep rose, and are produced on upright stems, from May to September on plants 12 ins. high. Its variety *glabra albiflora* is white.

M. tricuspidata.—The flowers of this hardy annual or biennial are rose coloured more or less intensified, sometimes white, and are produced from February to July, on plants 12–15 ins. high.

M. varia.—The flowers of this hardy perennial species are reddish, violet, or green, mixed with reddish-brown, and produced on nearly unbranched stems from May to August. Height, 3–12 ins.—J. F.

STOCKS FOR GRAFTING.—See *FRUIT CULTURE, HARDY: GENERAL CONSIDERATIONS.*

STOKESIA (Nat. Ord. Compositæ).

Only one species, an herbaceous perennial, is at all generally grown. This, *S. cyanea,* bears blue flowers in August and September, on plants 2 ft. high. Its varieties *praecox* (blue) and *praecox alba* (white) bloom earlier and are better. It is doubtfully hardy, so should be protected in cold districts in the winter. It succeeds in ordinary light soil, and is propagated by division of the roots in March.

STOKING-UP.

This is an important gardening operation. Light stokings are given usually at intervals of three or four hours throughout the day, but the final stoking, or "banking-up" as it is called, is usually done about 10 or 10.30 p.m. Furnaces differ widely in their nature, but they are usually so constructed that when nearly full they will burn for twelve hours without attention. The use of damp fuel, or the admixture of finely sifted ashes, ground lime, or limestone with the fuel is a great economy and makes the fire last a long time. Further suggestions in this direction will be found in our article on *FUEL ECONOMY.*

In the morning the furnace should be well raked to send the ashes through the grate, and at least once a week (about midday if the weather is very cold) the fire should be allowed to go out for a short time to allow for the furnace, flues and lower furnace where the ash is, being well cleaned out. The chimney should be swept at least twice a year to prevent firing of the soot.

STOVE PLANTS.

These require great heat and a constant tropical atmosphere. Houses have to be specially built for them, and large quantities of water have to be thrown about daily to keep the air for ever saturated with moisture.

Our readers will thus see that the culture of stove plants is by no means simple, easy, or inexpensive. Indeed culture of these numerous beautiful subjects is getting less on account of the high cost of maintaining the houses, and the constant care that has to be bestowed on the plants before any reasonable success is obtained.

As our work is a popular work, we have, after careful consideration, decided to exclude the ordinary run of stove plants from its pages, devoting the space they would occupy and much more, to hardy herbaceous plants which are ten times as beautiful and twenty times as useful. The chief greenhouse plants and a few stove orchids are mentioned, but these are of comparatively easy culture even for beginners.—E.

STRANGLE TARE (*Vicia lathyroides*). See *VICIA.*

STRANVAESIA.—For the best species see *SHRUBS.*

STRATIFIED ROCKS.—See under KINDS OF ROCKS in *GARDEN GEOLOGY.*

STRAWBERRIES (*Fragaria.* Nat. Ord. Rosaceæ).—In preparing for these, first give the ground a coat of 6 ins. of well-rotted stable dung; then trench this in 2 ft. deep, working the dung in as the work proceeds. Let the land settle for at least a week, and then tread firmly, raking the surface to get a crumb of fine soil.

Plant out your Strawberries in rows 2 ft. asunder, with the plants 1 ft. apart in the rows. It pays to buy plants in 3-inch pots, as these are well rooted, and, of course, they should not be set deeper than they are in the pots. Where runners are used, plant carefully with a trowel, spreading the fibrous roots well out, and making the soil firm round the crowns. In both cases hoe the ground over when planting is completed, and if possible give a light dressing of long stable dung as a mulch; this will give the plants a good start. The deep trenching enables the plants to resist drought in dry seasons, but watering is sometimes needed. The usual strawing down in early June should be given after a good hoeing.

The beds can be made from August to Christmas. It is a good plan to make fresh beds yearly and to destroy the oldest, as beds over two years of age do not give large fruits. Where strawberries are required for preserving, however, beds may remain for five years. The best preserving berry is *Garibaldi,* sometimes called *Stirling Castle*; its real name being *Vicomtesse de Thury.* In bottling, this variety remains whole.

Reliable Strawberries. — The old variety *British Queen* is omitted, as it does not crop sufficiently well.

Dr Hogg of the same race is preferable. Its fruit is wedge-shaped and of exquisite flavour. Another grand strawberry, *Countess*, is wedge-shaped, and has dark red fruits of extra fine quality, but is not a great bearer. These two may be called epicure fruits. We describe a few of the best varieties below :—

Fillbasket.—Fruit of medium size and of rich fine flavour. Enormous bearer. Mid-season variety.

Givons' Late Prolific.—A grand variety for the final crop. Fruit large, deep red, well protected by foliage,—an important point in a dry season. Flavour very rich. Good bearer.

Hibberd's George the Fifth (not to be confounded with the other Georges).—Fruit similar to *Royal Sovereign*, but much later and of splendid flavour. Berries large, and plant very productive. From the famous Southampton district.

Louis Gauthier.—A splendid sort, with pale pink and white fruits. The first or "King" fruits are very large and cockscomb-shaped. They are round on second gathering, and are produced in enormous quantities. The flesh is soft and pleasant, and the fruits should be gathered direct into the dish. Every gardener should grow this.

Royal Sovereign.—Where only one sort can be grown, this is undoubtedly the best. It comes early, the fruits are large, and the plants continue to bear for a long time. The flavour is fairly rich and the crop enormous.

Sir Joseph Paxton.—Fruits deep red and glossy. A good bearer and quite hardy. First rate when fully ripe. This is a great market variety.

Autumn Bearing Strawberries.—These fruit in the usual season, and again in September and October. Quite a number are now offered; but growers will do well to plant *St. Fiacre*, the fruits of which are very large and fine in flavour. *St. Antoine de Padoue* is another good sort, with smaller but very freely produced fruit. These late berries are useful in shooting time.

Alpine Strawberries. — Of these, which fruit in the autumn, the best are *Rouge Amelioreè* and the White Alpine, with *Bergere* red. They form neat edgings to borders, and can be planted 9 ins. apart each way.—G. B.

New Variety.

Strawberry The Duke.—This is much earlier than *Royal Sovereign*, also brighter in colour, and sweeter.

STRAWBERRY BUSH (*Euonymus americanus*).—See CLIMBING AND TRAILING PLANTS and SHRUBS.

STRAWBERRY CLOVER (*Trifolium fragiferum*).—See TRIFOLIUM.

STRAWBERRY LEAF SPOT and **STRAWBERRY MILDEW.** — See DISEASES OF PLANTS.

STRAWBERRY NETTING.—See under TANNED NETTING in GARDEN NETTING.

STRAWBERRY SNAIL.—See under SLUGS AND SNAILS in INSECT PESTS.

STRAWBERRY TREE.—The genus ARBUTUS and *A. Unedo.* See SHRUBS.

STRAWY MANURE. — See HORSE MANURE.

STRAY CATS AND DOGS. — See GARDEN ENEMIES.

STREAMLET SAXIFRAGE (*Saxifraga aizoides*).—See SAXIFRAGA.

STREPTOCARPUS (CAPE PRIMROSE. Nat. Ord. Gesneraceæ).—This, remarkable for its continual succession of bloom, has been brought to a high state of perfection by careful hybridisation. The hybrids may be had in flower nearly all the year round. They are propagated by seeds in gentle heat in spring, and also by divisions, and

should be set in good turfy loam, leaf-mould, and sand. Temperature required, 40–50° F.

Greenhouse Species and Varieties:—*Streptocarpus caulescens.* — Pale blue. Flowers in June. Height, 1 ft.

S. Dunnii.—Pale to bright rosy-red. Flowers in May. Height, 1 ft.

S. Galpini. — Mauve-blue. Flowers in May. Height, 1 ft.

S. New Hybrids. — Various colours. Flowers from May to November. Height, 1 ft.

S. Rexii. — Blue. Flowers in June. Height, 1 ft.

S. Wendlandii. — Blue. Flowers in May. Height, 1½ ft.

NEW VARIETIES.

Streptocarpus Rose Queen.—This has very large, bright rose flowers with a white throat.

S. Southgate White.—This carries two to four flowers on a stem. They are pure white, with a lemon-yellow band to the throat.

STREPTOSOLEN JAMESONII (Nat. Ord. Solanaceæ).—This is a free-flowering evergreen climber or pot plant, and may also be used for mixed borders outside in the summer. It is propagated by cuttings in the spring in mild heat, and should be potted into light, rich loam, peat, and sand. Temperature required, 40–50° F. It bears clusters of bright orange flowers from June to September, and the height is from 2–4 ft.

STRINGLESS BEANS (Tall). — See *BEANS.*

STRIPE ON TOMATOES.—See under TOMATO STRIPE in *TOMATO DISEASES.*

STRONG-SMELLING CLEMATIS (*Clematis orientalis*).—See *CLIMBING AND TRAILING PLANTS.*

STRUTHIOPTERIS.—Now included in the genus ONOCLEA, for which see *FERNS AND FERN GARDENING.*

STUARTIA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

STUD FLOWER (*Helonias.* Nat. Ord. Liliaceæ). — Although not much grown the Stud Flower is well worth including in the herbaceous border, where it will flower freely if a damp, lightly shaded site is provided for it, with a little peat in the soil. The only recognised species now is *Helonias bullata* (Syn. *H. latifolia*), a pretty purple-flowered plant blooming in April and growing about 12 ins. high. Four other species are now united with other genera, and two of these (*H. glaberrima* and *H. laeta*) are described under *ZYGADENUS,* which see.

STYRAX.—For the best species see *SHRUBS.*

SUB-TROPICAL BEDDING. — See *BEDS: SHAPE AND CHARACTER OF.*

SUBSOIL.—See under TRENCHING in *SOIL CULTIVATION.*

SUCCESSIONAL CROPPING. — See under DOUBLE CROPPING OR SUCCESSIONAL CROPPING in *ROTATION OF CROPS AND DOUBLE CROPPING.*

SUCCISA. — Now included in the genera CEPHALARIA and SCABIOSA. See *SCABIOUS.*

SUGAR BEET.

This is one of the Beetroot family, and came into great prominence during the sugar shortage of 1917–1918. It is a very easy crop to cultivate, much easier indeed than ordinary long beetroot. The question of extracting the sugar from the roots is quite another matter, however, and, candidly, we do not recommend amateurs to attempt it. Various lengthy prescriptions have been published instructing one to boil the beet in its skin till soft, then to peel, and finally to cook it well in a boilerette for twelve to twenty-four hours, after which the syrup is stored in air-tight bottles.

But the sugar extracted by this method is not satisfactory, and the syrup does not keep. Used, however, as a second vegetable, sugar beet is most delicious. The present writer grew some on a war plot during 1918, and had it stewed in a similar manner to ordinary beetroot. He was much struck with the delicious flavour, especially when served up with a suitable gravy. The idea that sugar beet is too sickly for this purpose has little foundation in fact, and this useful vegetable is sometimes overlooked by reason of the accounts which have been published of its sickly insipid character.

Culture.—As already pointed out, sugar beet will grow without difficulty. The plant is possessed of a very strong tap-root, and although well-worked soil, trenched to the depth of 1 yd., is the best medium in which to grow it, it will do very well in a soil only dug in the ordinary manner, and its root will find its way through the subsoil to the moisture below. The seed, which is large, should be sown very thinly, one cluster being put at least 9 ins. from the next, and if the clusters are very big they may be broken into two or three pieces. Drills should be taken out about 14 ins. apart and 1 in. deep, the seed being covered after sowing with ordinary soil. When we have made the drills fairly firm we must leave Nature to do the rest.

The time to sow varies with different districts. If the seed is sown too soon and the district be hot and the soil light, the plants will run to seed; then the roots are very similar to iron and quite as difficult to cut! The writer remembers well attending a lecture in a provincial city on the question of sugar beet. The lecturer was unconventional enough to bring some of the beet with him, and he handed round some shredded root on sheets of writing-paper. The audience entered into the spirit of the thing and took a good pinch of the shredded beet, munching this throughout the lecture. They were not struck with the edible nature of the raw beet, but were convinced of its sugar-bearing nature. The lecturer also brought one with him which had run to seed, and offered a large reward to anyone who could cut a small piece out of it. Several of the audience endeavoured to do so, without result, as the beet, which had run to seed, was too tough to be cut with a knife even of best Sheffield steel. So to return to our point, where the soil is light and the district hot it is a mistake to sow this crop too soon, unless early lifting can take place, for the large roots will be useless if the plants go to seed. About the middle of March is a safe time to begin sowing in districts where the soil is not a hot one, but any time throughout April, until the second week in May, will do for the sowing of the crop.

As soon as the seedlings appear the rows should be thoroughly well hoed. Early thinning is essential should one cluster of seed have produced five plants, as is quite likely. The strongest should, of course, be left and the others removed. They can be transplanted into new ground provided that the long tap-root is kept straight.

The after culture of sugar beet is very simple. No water, no manure, no feeding, and but little cultural treatment save frequent hoeing is required. The only pest that proves troublesome is the Beet Fly, which will be found in our article on *Insect Pests*, and the plant, being a stronger growing one, is but little troubled with any

of the diseases which play such havoc among other crops. The roots should be lifted in November before severe frost comes, and stored in a similar way to Carrots.

Variety.—The sort which proved most useful during the sugar shortage above referred to was *Ryder's Saccharina.* The roots of this have a high precentage of sugar in them.

E. T. E.

SUGAR CORN.—See *MAIZE, or INDIAN SUGAR CORN.*

SUGAR MAPLE (*Acer saccharinum*).—See *TREES.*

SUGAR OF LEAD.—See *LEAD COMPOUNDS.*

SUGAR PEA (*Pisum Sp.* Nat. Ord. Leguminosæ).—The sugar, or edible-podded pea is not largely grown in our gardens. Yet the unique characteristics of the crop are such that should ensure it fuller notice from amateurs and lovers of vegetables generally, who like their gardens to contain a great variety of distinct yet profitable crops. It is not only in the pods, but also in the colour of the flowers that this type of pea differs from the ordinary culinary pea of our gardens; and as the plants grow to a very considerable height, the ornamental value of a well-grown row is such that should commend them to small owners or others who would think a row of the ordinary peas out of place so near the lawn or flower garden.

Culture.—If given good cultivation the Sugar Pea is a very heavy cropper, but it is important the pods be gathered early, as if they are gathered too late they are worthless for food, while their retention on the haulm prevents the free-setting and development of other pods.

Seed may be sown any time from the middle of March until the end of May, and thin sowing should be followed, an over-crowded row quickly becoming covered with mildew, or failing this, the pods seldom attain full size.

Sticks should be provided early in growth, and during periods of drought water should be applied freely both to the roots and overhead. The pods are cooked whole, nothing but the top and tail of each being removed.

Varieties.—The number of varieties is not numerous, but of late years Messrs Barr & Sons have devoted considerable attention to the improvement of these little-known occupants of our gardens, and have greatly improved the older sorts.—F. R. C.

SUMMER GARDEN, THE.

If we study the four seasons of the gardening year, autumn, winter, spring, and summer, we cannot fail to remark that the summer garden is far the most beautiful of any season's garden. Winter has a barren beauty of its own. Spring has the glorious beauty of a new awakening, when everything is so fresh, in its first unmarred condition of purity and loveliness, when the whole face of nature seems as beautiful as the innocent faces of happy children. Autumn has its lovely colours, its aftermaths, its perfection and yet pathos; for it speaks of the cold winter to come. All the seasons have a beauty of their own, but that of the summer garden excels the others many times over. It is, as I have often said, the superlative season as regards beauty in the garden; the loveliness of the other seasons may seem great, but it is not to be compared with that of the summer garden.

What a joy it is to roam about in a well-worked summer garden! A poet has wrongly said that the most supreme joy anyone can have is to sit under trees and watch the flowers bloom—a pretty idea some will say. But I fear that is not my own feeling nor the feeling of many another who is truly fond of flowers. There is a desire to do more than sit in the shade and watch them grow; there is the desire to be amongst them, to feel their presence, and to see them smiling at us as we go amongst them. If I were a flower I should severely scorn the people who get some one else to do all the work of planning, planting, and tending the needs of flowers. These people, I should think, were not worth wasting my smiles upon, and I should close up my petals and draw up my leaves as they passed.

I wonder why people who do not really love flowers trouble to pay for the production of lovely summer gardens? This is a question which it is not very easy to answer. Certainly the class of person who lolls about in an easy-chair, or lies lazily in a hammock looking at the flowers, and yet not lifting a finger on their behalf, does not, cannot, love them. He may *think* he does. He would be fearfully angry if any one accused him of lack of love for flowers, yet there it is. Perhaps the answer to the question is found in the statement that these people have their gardens planned, planted, and tended by other people on account of a false pride. They think that it is "the thing" to have a lovely garden; it is certainly "the thing" to have "the loveliest garden in the county," and these people feel an inch taller if not two inches when that statement is made by a

Duchess or some other infinitely great personage!

This sort of thing is detestable. People who have this form of pride are always people to be avoided. To see one of these folks lolling about, when close by are masses of lovely flowers speaking or begging for care and personal attention, is a sight worth witnessing once, but not again. It is too painful to experience a second time.

The summer garden, then, should be all beauty and no pathos. Remove the languid, lolling, careless owner of it, and give it your own personal attention as well as any attention it may have to have from a gardener; then you will obtain what is far more precious than any form of riches—a perfect garden.

There will be a glorious lot of colour in this summer garden. It will probably be mostly greenery in the month of May, but in June its glories should commence being boundless. Green will gradually get less and less; it will never wholly disappear, but in July and early August, when the garden will reach its zenith as regards loveliness, there will not be a great deal of green on the surface. Instead there will be mass upon mass of all the colours of the rainbow, and many combined shades of colour as well, all arranged so that they do not clash from whatever spot the garden is viewed. The plants in this perfect summer garden will all of them be the picture of health; they will show that personal love and care have been showered upon them by some one who loves each of them individually. A touch here and a touch there from the loving hand of someone who does it because he loves doing so, and is not paid to touch and often to spoil, will make a mighty difference. Often what is impossible to obtain by the hand of the paid gardener, is accomplished by the man who does it for love.

There will be no dots of indefinite undecided colours in this perfect summer garden. Such are not worthy of a place. There will be splashes of colour, which any real flower lover so often longs to see in the gardens of his friends. There may be fewer varieties this way, but there will be more beauty, which is what we want.

There will be long, long borders, with winsome winding walks or little paths, down which we can wander in the cool of the evening, or for that matter at any time. As we stand at one end of any of these borders we shall be able to see flowers before us, and flowers far far away even in the distance. And this will prove a fitting introduction to joys which are yet to come.

There will be perfect pergolas in this perfect summer garden. Masses of pink, crimson, and white roses of delicious scent will hang down on all sides, and such a picture will probably make us think of the beautiful garden which awaits us in the next world.

In a low part of this lovely summer garden there will be a cool glade and a delightful pool or pond of crystal water. Around this will grow large quantities of lovely, showy water-plants. There will be no temples, garden huts, bridges, or other equally ugly garden paraphernalia to mar the picture of quietness and beauty. There may, it is true, be a neat little garden summer-house hidden away in a nook, or if this cannot be managed, the garden summer-house may be covered with entrancing rambler roses to turn its ugliness into loveliness.

In one part of this lovely garden there will be a spot set apart for simple scents. To this portion we

repair when we want our nose to be entranced after our eyes have been blinded by the beautiful colours we have passed. Such a corner should contain all the older pot-herbs, most of which are quite attractive plants as well as easy to grow; and then throughout the summer we shall never lack that happy feeling always experienced by an entrancing odour. Scents are encouraging things. They may take us back years, to some time when we were little children, and we tried to do some great, brave thing—and succeeded. A scent seems to stimulate both mind and body. We are apt to think as we fulfil our every-day tasks at our machine or at our desk, that effort does not really matter, especially if the consequences of failure in any undertaking may not be great. But a delicious scent stimulates us; it makes us decide that we *will* succeed, we *will* do our very best, whatever happens, and after that things come much easier.

Adjacent to the cool, refreshing pond there will be a rambling rockery, where plants can romp and run riot to perfection without ruining or suffocating anything else. Here we shall learn again of the glory of form, and of the magic of colour; we shall see sheets of superb colour—yards of yellow, bands of blue, splashes of purple, carpets of crimson, oceans of white, ridges of rose, and captivating corners of every other lovely colour. If we have not learnt what colour means in our flower borders, we shall learn this here, and there will not be many (except, of course, hardened sinners) who will not give a dear little gasp of ecstasy as they see that perfect rock garden. Bacon has said that "God Almighty first planted a garden," and the Bible tells us that the first garden to be planted was the Garden of Eden. We can make our own garden like the Garden of Eden by massing colours, and though we can never attain anything so truly perfect as God's garden must have been, yet the effort to make it similar will do us much good.

In our perfect summer garden ugliness can have no place. All ugly accessories must either go for good or be completely concealed. Ornateness also is not what we want. Thus we must leave special gardening of such sorts as Chinese Gardening, Italian Gardening, etc., severely alone. I do not think a garden can be perfect in Britain unless it is an all-British garden; British I mean to the backbone as regards its construction, arrangement, and management. We shall probably include plants in it which are not all British, but that does not matter, so long as we keep foreign freak-plants out of it, which plants are often ugliness incarnate, in spite of their novel appearance. Paved paths, fantastic bridges, isolated poles, minaretted summer-houses, Japanese huts, terra-cotta tiles, and other similar innovations should be rigidly kept out of the summer garden if it is to be perfect. The same may may be said of every example of topiary work, and of formal bedding. These may be all right in suitable surroundings, but for pity's sake keep them out of your summer garden, since they, with their frequent hideous ugliness and equally detestable foreign appearance, will completely spoil its effect.

Let things be done "decently and in order," as the Prayer Book says, in the summer garden. Keep things at their best for the longest possible period by avoiding neglect at any time. But let things go their own way and only give support as they require it. Think of the natural way the plants grow in

woodlands and hedgerows, and try to retain in your summer garden as much of this beauty as you possibly can.

I must now conclude this rather rambling sketch. You and I, reader, must return to earth and to commonplace things after our chat about, and our view of the summer garden. Word limits are an awful nuisance when one gets talking about summer gardens with all their beauty and their joys, and although we have only touched upon a fringe of this great subject we must, however reluctant we may be, conclude our chat at this point.—E.

SUMMER SAVORY.—See *SATUREIA,* also under SAVORY in *POTHERBS.*

SUMMER SNOWFLAKE (*Leucojum aestivum*).—See *SNOWFLAKE.*

SUMMER SOWING. — See *ALLOTMENTS: MANAGEMENT OF.*

SUN ROSE.—See article on *HELIANTHEMUM,* and see HELIANTHEMUM in *SHRUBS.*

SUN SPURGE (*Euphorbia helioscopia*). See *EUPHORBIA* and *WEEDS.*

SUNDEW (*Drosera.* Nat. Ord. Droseraceæ).—This is a family of dwarf-growing plants suitable for bog, water, or wild gardens. *D. intermedia* is white; *D. longifolia* (Syn. *D. anglica*) is red and white; while *D. rotundifolia,* popularly known as the YOUTHWORT, is white. All bloom from June to July, and average 3–4 ins. in height.

SUNDIALS.—See *GARDEN FURNITURE.*

SUNFLOWER (*Helianthus.* Nat. Ord. Compositæ).—The ANNUAL SUNFLOWERS are at once showy and useful plants in the garden, and the *Giant Russian* and *American* forms, which grow from 5–10 ft. high, have a distinct economic value, inasmuch as the ripe seeds, produced in big, flat heads, are valuable as poultry food, and a useful oil is expressed from them.

Culture.—All the annuals may be raised from seeds sown in March or April out-of-doors, or earlier in pans or pots in a frame or greenhouse. Transplanting is desirable so that the plants may have ample space and develop according to their type. The bushy *Stella* forms need as much room as a Dahlia, and similar support. They bloom freely, and are useful for cutting, or for planting in large beds or among shrubs. We recommend the following:—

Helianthus annuus.—This is the common GIANT SUNFLOWER, producing yellow flowers in the summer and autumn. It grows 5–12 ft. in height, and is useful as a screen to fences. There are several varieties: *Golden Nigger* has a dark centre and deep yellow rays; *Primrose Perfection,* primrose-yellow; and *Sulphur Gem,* pale yellow. There are also double-flowered forms in several shades of colour. The *New Red Sunflower* is a distinct type and has chestnut-red colouring, with yellow tips; there are several variations, and *Langley Gem* (old rose over primrose) is one of the best.

H. argyrophyllus is a yellow-flowered, summer-blooming Texan plant, somewhat like *H. annuus,* but not so useful in gardens. Height, 6 ft.

H. debilis.—This also is a native of Texas. It is a yellow, much branched, summer flowering sort. Height, 4 ft. *H. cucumerifolius* is probably a form of this, and from it the bushy Sunflowers so eminently decorative in the garden have been evolved. These flowers are of moderate size; some have flat

florets, and in others the rays are more or less quilled, after the fashion of a single Cactus Dahlia. Of this type some of the best varieties are *Apollo*, yellow and maroon; *Mars*, yellow and purple-red; *Orion*, golden-yellow; *Primrose*, pale yellow; *Princess Ida*, cream-white, with yellow zone; and *Stella*, deep yellow. There are now some bronze-red forms of this group, and a dwarf strain rarely exceeding 1 ft. in height.

Perennial Border Species.—The hardy perennial Sunflowers are very popular plants for herbaceous borders, and would be more so if they did not spread quite as rapidly as they do. Certainly the flowers are glorious, and their beauty adds much to our often golden autumns.

CULTURE.—The perennial sorts are quite as easy to grow as the annuals just given, and are much easier than many other hardy border perennials. The soil should be ordinary well-worked garden loam, enriched with some old manure, and the situation should be sunny. Plant any time from November to March, and where no stem portion is visible on the roots supplied, bury the pieces about 6 ins. in soil. Careful staking is desirable, unless the site is sheltered. The plants grow very rapidly, and frequent ties are advisable in windy districts. They need but little water however hot the season may be, and to mulch them is an unnecessary extravagance.

Propagation is a simple and easy matter. Division of the rootstocks is the best method to adopt, and every bit of underground stem will grow. The work can be done in the late autumn or spring. They may also be raised from seed sown in March or in the summer, the young plants being duly pricked off and planted out in the usual way.

USES.—Perennial Sunflowers are useful both in herbaceous borders and shrubbery borders, as well as in the wild garden. The flowers of most species are splendid for cutting, lasting well in water. The dry stems provide useful fire-lighting material in the autumn and winter.

What to Grow.—If the Sunflower lover will visit a botanical garden in the late summer or autumn he will find a host of sorts to choose from. We recommend the following:—

Helianthus angustifolius.—A bright yellow kind flowering in September and October. Height, about 2½ ft.

H. decapetalus or *divaricatus.*—A yellow or orange-yellow September blooming sort, 5 ft. high.

H. giganteus (also known as *H. altissimus*). — A yellow autumn flowering species about 10 ft. high.

H. laetiflorus. — An attractive yellow August blooming species some 8 ft. high.

H. mollis.—A yellow or orange-yellow species blooming in September till the frost cuts it down. Height about 4 ft.

H. multiflorus.—This is a favourite species of which there are many varieties both single and double. The flowering period is maintained from July to November, and the height averages 5–8 ft. We recommend the following varieties of it: *Bouquet d'Or*, double golden-yellow; *major*, yellow; *maximus*, single golden-yellow; *Queen Victoria*, a splendid double yellow; *Soleil d'Or*, a favourite double yellow; and *The Pearl*, chrome-yellow.

H. orgyalis.—An autumn blooming yellow species about 9–10 ft. high.

H. rigidus.[1]—This is probably the most favourite species of all. Its flowers are various shades of yellow, and it blooms from August until the frost cuts it down, ranging in

[1] The PRAIRIE SUNFLOWER.—EDITOR.

height from 3–6 ft. There are many varieties. We recommend the following: *Aestivus* (or *japonicus* of the nurseryman), yellow; *Daniel Dewar*, yellow, dark centre; *elegans*, yellow; *grandiflorus*, large yellow; *Miss Mellish* (a favourite orange-yellow variety); *Miss Willmott*, yellow; *praecox*, golden-yellow; and *Rev. C. Wolley Dod*, yellow.

H. sparsifolius. — A first-rate yellow variety flowering in the late summer and autumn. Height about 6–8 ft.

SUPPLY AND DEMAND.

Perhaps I may be allowed to touch briefly upon the great question of supply and demand in the garden, for many gardeners err about it.

In May and June our crops come on well, and peas will be ready for gathering well before Midsummer Day. Naturally the crop at first is small, but as the summer months go on it gets greater and greater, till the gardener finds he has more than he can deal with at the time. So the crops spoil. This waste can be avoided with a little thought and common sense. Many people leave their young peas on the plants, for instance, till the pods are well filled and until the young peas taste and feel old. It is not good policy to do this, especially considering what a true luxury a dish of young peas is; and it is not wasteful to use them when comparatively young as some imagine, for it avoids the later crop coming all at once and being spoiled as it so often is. Peas should always be eaten when quite young, for then the plants take fresh strength, and indeed are not so exhausted as if the crop had been left on until the pods are filled with hard peas. Moreover, a removal of all suitable pods gives the others a far better chance of being tender when cooked, and, of course, prolongs the crop. If, however, the young peas are left on till they are tough and old it will be found that only quite a few gatherings can be made before the peas are quite uneatable, and if the rows have no more care than a mulch of mowings or manure and an occasional hoeing, the plants will soon have to be pulled up and thrown away. It is genuinely impossible to eat the crop off three or four rows if it is all ready together without letting some of the crop go to ruin as too old. Successional sowings of peas—and my remarks above also apply to beans of all kinds—do not counteract the evil of a glut at one time, for with early sowings it often happens that two rows sown a fortnight after each other come into bearing at the same time. But with later crops the successional sowings act rather well: one finishes a certain row and then goes on to the next one. If carefully managed these later sowings should produce no excess of supply of peas.

The same thing applies to lettuces, radishes, and smaller crops. To take the second first we may say that unless the crop be started when quite young and before it is what gardeners term "ready," a great waste will result in sowing a large bed or long row if there are not a great number of people to consume the crop. To sow "little and often" is by far the best way to avoid this waste, and at the same time to obtain a nice crop of tender radishes. About the lettuce we may say that much should never be sown

unless there be a great demand. Many sow a large bed and leave the seedlings in it till they are all ready to eat, and inevitable waste results. Besides this, if one does not actually waste the lettuces, those that are left are tough and not acceptable.

Then there is the common practice of planting out seedling lettuces that they may grow into large plants. Sometimes the average gardener will put out a hundred or a couple of hundred plants at a time. Now this is all very well if one wishes to supply a mansion full of people, but otherwise the gardener should never put so many out together. If he does, it is likely that ever so many of the plants will be ready at the same time. What he is not able to use are likely to "bolt" and then they are no good. If, however, he lands himself—by miscalculating the consumers—with a large batch of lettuces ready to eat, let him see the cook about having a dish sent in as spinach. His supply will then be used ere it spoils.

There are many other instances of how necessary it is for the gardener first to study the demand, and to regulate the supply accordingly, but I have no space left to refer to them here.—E.

SURFACE CROPS.—See *KINDS OF CROPS.*

SURFACE CULTIVATION.—See *SOIL CULTIVATION.*

SWAMP HONEYSUCKLE (*Azalea viscosa*).—See *AZALEA: HARDY SPECIES,* and *RHODODENDRON. Rhododendron viscosum* is another name. See *RHODODENDRON.*

SWAMP WHITE OAK (*Quercus bicolor*). See *TREES.*

SWEDES (*Brassica Sp.* Nat. Ord. Cruciferæ).—Although the merits of these as a winter vegetable have long been appreciated by the poorer classes, especially those living in country districts, it was not until the prolonged frosts of 1916 destroyed nearly all the usual winter crops, that the value of the swede as an article for human consumption was brought to the notice of the upper and middle classes.

During that time as much as fourpence was freely paid for a moderate sized specimen, and many who during those weeks tasted swedes for the first time, were so favourably impressed with the table quality, that in many households to-day they are equally as popular as the white or yellow turnip.

Most of our leading seedsmen offer superior strains for gardens, and these should always be grown in preference to the larger and coarser roots grown exclusively for cattle.

Culture.—Seeds may be sown any time from early in May until the beginning of July, the latter sowing being advisable where none but medium sized roots are required, earlier sowings having become too large and the flesh of a woody nature before real wintry weather need be expected. As the roots continue to develop throughout a mild winter, little fear need be entertained of a late sowing being anything but profitable to the grower.

Always select a well manured site for the bed, raking the surface down very fine previous to sowing the seed.

Sow in drills 15 ins. apart, allowing not less than a foot between each plant. Gaps in the run may be filled by transplanting the surplus taken from overcrowded portions of the run.

After thinning out, treat exactly as advised in the article on *TURNIPS*.

Varieties.—Champion Purple Top, Laing's Garden Swede and Lord Derby are good sorts.—F. R. C.

SWEDISH WATER LILY (*Nymphaea alba rubra*).—See *WATER LILIES*.

SWEET ALMOND (*Prunus Amygdalus dulcis*).—See *NUT CULTURE* and *TREES*.

SWEET ALYSSON (*Alyssum maritimum*), **SWEET ALYSSUM** (*Alyssum maritimum*).—See *ALYSSUM*.

SWEET BASIL (*Ocimum Basilicum*).—See *OCIMUM*, and under BASIL in *POTHERBS*.

SWEET BAY.—The genus LAURUS. See *SHRUBS*.

SWEET BUCKEYE (*Æsculus flava*).[1] See *TREES*.

SWEET CHESTNUT. — The genus CASTANEA, which see in *TREES*. See also under CHESTNUT in *NUT CULTURE*.

SWEET CICELY (*Myrrhis odorata*. Nat. Ord. Umbelliferæ).—This comparatively well-known plant has a pleasant smell of myrrh, and is sometimes known as the BRITISH MYRRH PLANT. Its white flowers, produced in May on plants nearly 1 yd. high, make it useful for mixed and herbaceous borders. Botanically it is a hardy, herbaceous perennial, and thus succeeds under the ordinary treatment usually given to these subjects, though it seems to prefer a somewhat moist, shady spot rather than a dry one in full sun. Propagation can be effected by division of the roots, by cuttings, and by seeds at the usual times, and the best period for planting is March.

SWEET CORN.—See *MAIZE, or INDIAN SUGAR CORN* and *ZEA*.

SWEET FLAG.—See *ACORUS* and *WATER GARDEN: PLANTS FOR THE*.

SWEET GUM (*Liquidambar styraciflua*). See *TREES*.

SWEET LAVENDER (*Lavandula dentata*).—See *LAVANDULA*.

SWEET MARJORAM (*Origanum Majorana*).—See *ORIGANUM*.

SWEET PEAS (*Lathyrus odoratus*. Nat. Ord. Leguminosæ): **History.**—The first mention of this flower in England is a reference to seed sent from Sicily to Dr Uvedale at Enfield in 1699 by Cupani, an Italian monk, and a drawing of a plant grown from Cupani's seed by Caspar Commelin occurs in the *Horti-Medici Amstelodamensis* (1697–1701). This wild variety with purple flowers was first offered for sale in England about 1730. By 1793 purple, white, Painted Lady, "black," and scarlet varieties were catalogued, followed by striped and "yellow" before 1840. A picotee with blue colouring appeared in 1860, said to be a cross with Lord Anson's Pea (*L. magellanicus*), and the firms of Carter, Laxton, and Sutton introduced a few more before Henry Eckford took up the flower and laid the foundations of its present popularity.

Several of his raising are still favourites, *e.g.* Dorothy Eckford, Lady Grisel Hamilton, King Edward VII., etc. Countess Spencer, the first waved Sweet Pea, was raised and exhibited in 1901 by Mr Silas Cole, and Messrs R. Sydenham bought and distributed the stock. In the same year Mr W. J. Unwin raised Gladys Unwin, of somewhat different form, and from these two pinks, especially the former, have come all the modern varieties and improvements.

Cupid or dwarf Sweet Peas originated with Messrs C. C. Morse & Co., at Santa Clara, California; and Bush Sweet Peas, which are of medium height and less robust than

[1] The name SWEET BUCKEYE is sometimes applied to *Æsculus octandra*, but the name is not sufficiently fixed to warrant its general use.—EDITOR.

the tall type, are also an American introduction. Neither type has found much favour here, probably because our climate is not sunny and dry enough for them.

Winter-flowering Sweet Peas have of late years become popular for market and conservatory use. Said to be derived from the White Blanche Ferry, they have been greatly improved by the Rev. Arkwright, Messrs Engelmann of Saffron Walden, and Zvolanek of New Jersey, U.S.A. The wave form is now established in this type, and a new race of which the fine bicolor Yarrawa is the parent has been raised by Messrs Yates in Australia.

Soil and Situation.—There are two primary essentials to the successful cultivation of Sweet Peas, namely, plenty of light and air above ground, and plenty of depth of good rich soil for the roots below. If these conditions alone exist, a charming display of decorative blossom may be obtained, but, of course, higher culture is needed to ensure really good flowers and a long flowering season. Sweet Peas should be planted in an open, airy, and sunny situation away from other tall subjects. The soil must be well drained and of considerable depth. On shallow gravel or chalk soils and on cold heavy clays, success can only be obtained with hard work; a deep rich loam suits them best, but with careful and thorough tillage exhibition blossoms may be produced almost anywhere.

Preparing the Site.—The soil should be trenched to a depth of at least two spits, even three and four is not too much, and the ground at the bottom of the trench should be broken up and decayed manure added to it. The trench should be not less than 4 ft. wide for a row, and 4 ft. square for a clump. In light soils a layer of fresh manure placed at the bottom of the trench helps to retain moisture, but this practice is not wise unless trenching is done some months before sowing, as Sweet Peas often develop disease, when their roots come in contact with raw manure. In heavy soils the bottom of the trench should be filled in with old, well-rotted manure, burnt earth, road scrapings (free from petrol or tar), and anything likely to help drainage. When the soil lacks lime, it should be added as work proceeds, as should also well-decayed farmyard manure with potash and phosphatic fertilisers. The soil should be replaced as thrown out, adding soot and wood ashes to the top spit, which should be left rough, whereas the other spits should be made firm by treading. For spring planting and sowing, trenches should be got ready in autumn; for outdoor autumn sowing as early in summer as possible, at least six weeks beforehand.

Manures. — Farmyard manure should be used when trenching at the rate of approximately two barrow loads per rod, cow and pig manure on light soils, stable manure on heavy ones. Other organic manures are guano, fowl, and pigeon dung, sewage, and soot, any of which can advantageously be used in liquid form as a stimulant in summer, being applied well diluted once or twice a week after rain or a good watering. Artificials are compounds of phosphorus, potash, and nitrogen. Of the first, basic slag, 3 oz. per sq. yd., should be dug in when trenching heavy land; on medium and light soils substitute bonemeal, 4 oz. per sq. yd., and superphosphate, 2 oz. per sq. yd. This last gives good results as a top-dressing in spring. Potash manures include wood ashes, which should be liberally applied when available. Kainit and sulphate of

potash, when obtainable, should be dug in when trenching, using 4 oz. per sq. yd. Flue dust from furnaces, which can be obtained from manure merchants, is said to be good. The writer has not had an opportunity of trying it yet.

Seeds and Sowing.—Obtain sound well-ripened seed, as true as possible, all varieties throwing a certain percentage of untrue flowers. Though germination gets slower, Sweet Peas retain their vitality for several years, and after a wet and cold summer year-old seed often gives better results than that freshly harvested. White and cream sorts have whitish seed-coats (the so-called " black seeded " whites and creams are not true albinos), lavenders and mauves are spotted and often wrinkled. Carmine, crimson, and picotee varieties have very thick coats, and it is often advisable to file or cut through the skin of these to ensure level germination. The cut should never be made where the pea was attached to the pod, as the embryo plant lies there and might be damaged, if not killed.

Sowing.—For exhibition purposes seed should be sown in pots or boxes either in autumn or spring; the former time is becoming every year more popular. One may use 3-inch pots for single seeds, 5-inch for four or five seeds, and boxes for more. Sow from mid-September to mid-November, or in the latter half of January and February, ½ in. deep and 1 in. from seed to seed, in a compost of three parts of fibrous loam, one part leaf-mould or thoroughly decayed manure, and enough sharp sand to keep the soil open. Whites, creams, and all shades of mauve require more sand and less water than other varieties. After sowing, water thoroughly and place in a cold frame on cinder ash or similar material. Keep the frame closed and give no more water till the seedlings appear, then ventilate freely, watering during winter only when the compost shrinks from the sides of the pots. To prevent the roots from freezing in sharp frost plunge the pots in cinder ash. Pot seed, sown in large pots and boxes singly into 3-inch pots about a month after sowing, and, if necessary, repot again in January. Sweet Peas are very hardy as regards temperature; we have known them come safely through a record of 2° F. without protection in calm dry weather when sown outside, but they are very liable to succumb to damp, so that care must be taken not to overwater frame plants and to give them good ventilation, taking the lights off altogether on calm and sunny days.

Outdoor sowings may be safely made on light well-drained soils in the southern half of England in September and October, and will give stronger plants and more flowers than spring sowings, which should be made from mid-February to April, according to the relative warmth of the climate and soil in one's district. Seed should be sown in two rows 18 ins. apart, with 2 ins. from seed to seed, or in rings of 2 ft. diameter for clumps. Sow 2 ins. deep in autumn, rather less in spring, and thin as soon as they are well started to about 6–18 ins. apart, according to the previous treatment of the soil.

Planting Out.—Harden off plants raised in frames during March, and as early in April as possible, when the weather is fine and the soil works well, plant out the young seedlings a foot to 18 ins. apart in double rows or clumps. It is important to plant firmly, and be sure to make the hole deep enough to allow the roots to grow down. We would not

advise cutting the roots, as some growers do, unless they are excessively long, in which case it is almost unavoidable. It is a good plan to stake finally when planting; in any case small twiggy sticks should be inserted as first supports for the tendrils. If the ground is very dry, water thoroughly the day before planting.

Staking.—For exhibition plants confined to two or three stems, disbudded and tied, long rods of bamboos or hazel are best. Stout stakes connected by wires should be driven firmly in at intervals along the row, and the rods should be firmly attached perpendicularly to the wires, the shoots as they grow being tied to the rods with raffia. For decorative plantations the tallest and twiggiest bean sticks, preferably elm or hazel, should be inserted very firmly upright on either side of the double row, with shorter twiggy sticks between them to make up for the absence of "spray" at the bottom of the tall sticks. Well-grown Sweet Peas will easily top 12 ft. or more in a season. In windy situations further support with stout stakes and connecting wires should be given. The best artificial supports are wire netting and Simplicitas netting.

Culture under Glass.—Sweet Peas sown early in the autumn may be flowered in a cool house instead of being planted outside. For this purpose they should be potted on as soon as the roots fill the pots. Kept in a cool frame till January, they should then be brought into the house and kept as near the light as possible. Five or six shoots per pot is ample, and these should be confined to one stem and tied to bamboos as they grow. Ventilate the house freely; do not try to force; water regularly, keep a good look out for green fly, which should be checked at once, and give weak liquid manure when in flower. For indoor work the modern waved early flowering varieties are better than the summer flowering type.

Exhibiting.—The following brief *vade mecum* will be found useful. Seed of the best waved varieties should be obtained from one of the many reliable specialists. The National Sweet Pea Society's Classification and Too Much Alike Lists will be helpful in making a selection. Careful and thorough attention to the details of preparing the ground, manuring and planting as already given, is essential, as success depends on a good beginning. Orange, salmon, and scarlet tints should be lightly shaded from bright sunshine, as they are likely to burn, but only lightly: too heavy shading destroys the brilliancy of the flower. Choosing a dry day, cut sprays with four or more flowers well placed on the stem, having the lower two blossoms fully open, the others less forward; do this as early in the day as possible and place loosely in hard water in a cool dark room. When packing squeeze the stems to drain off surplus water, wrap them in oiled paper, then wrap the whole bunch in tissue-paper and label it Pack the bunches firmly in well-ventilated boxes, without crushing, and on arrival at their destination put them in hard water at once with plenty of room. Arrange the sprays lightly and symmetrically in the vases, keeping the least satisfactory as much in the background as possible, and making sure that all are true to name and type. Arrange the vases in as effective a colour scheme as you can, keeping the taller and heavier vases to the back row.

Diseases.—Streak is the worst and commonest of all, and investigation has not yet fully elucidated its

cause. It is generally attributed to bacterial infection by the microbe *Thielavia basicola* and no certain cure is known. Plants attacked show the first signs in yellowing foliage, the leaves then turn brown and fall, the stem withers, the whole plant collapses and dies, blackish-brown streaks are found on the stem, the roots have few nodules, and these unhealthy or dead. It is most likely to occur in the case of plants too liberally treated with nitrogenous manures and after over-watering, but cold, excessive drought or rainfall and sudden sharp changes of temperature will bring it on. An adequate supply of lime, phosphates, and potash in the soil tends to make the plants disease-resistant.

Seedling Pea Blight is a black mould which attacks the plant through the root. Fungicides are useless; the plant must be pulled up and the soil treated with quick-lime. As preventives apply potash salts and lime. Another incurable disease is Clover Mould (*Peronospora Trifoliorum*), which attacks the leaves on which yellow streaks appear and spread. The foliage then turns brown and falls. Diseased plants should be burnt and the ground dressed with 4 ozs. kainit, 1 lb. basic slag; and before sowing with 3 ozs. superphosphate, ½ oz. sulphate of ammonia, and ½ oz. sulphate of iron per sq. yd.

Mildew on the foliage and stems and Pea Mould on the pods should be treated with a dressing of flowers of sulphur. For Pea Spot (*Ascochyta pisi*), which causes small yellow spots on the leaves that increase in size and run together till the leaves wither and fall, spray with Bordeaux Mixture.

Of pests, green fly is the only one to be feared, and a bad attack ruins the plants. Generally they are little liable to it, but if grown in too crowded or shady a position will suffer badly. Spray with any reliable insecticide several times at short intervals.

Varieties.—The following will be found a reliable selection of modern varieties:—

Bicolor.—Dora, Mrs Cuthbertson.
Blue.—Margaret Fife, Princess Mary.
Blue (dark).—Lord Nelson Spencer.
Blush.—Lady Evelyn Eyre, Mrs Hardcastle Sykes.
Blush, Lilac.—Agricola.
Carmine.—John Ingman.
Cerise Shades.—Edith Taylor, Illuminator, Marion, Sincerity.
Cream.—Dobbie's or Unwin's Cream.
Cream Pink (pale).—Duchess of Portland, Mrs H. Dickson.
Cream Pink (dark).—Margaret Atlee.
Crimson.—Maud Holmes, Mrs C. P. Tomlin.
Fancy.—Charles Foster, Prince George.
Flushed (rose on white).—Marchioness of Tweeddale.
Flushed (rose on cream).—Mrs J. Balmer.
Ivory.—Paradise Ivory.
Lavender.—R. F. Felton, Unwin's Lavender.
Lavender (pale).—Farnham Lavender, W. P. Wright.
Lilac.—Dorothy.
Marbled.—Birdbrook, Helen Pierce Spencer.
Maroon (dark).—King Manoel, Nubian.
Maroon (red).—Lord Fisher.
Mauve.—King Mauve, Mrs J. C. House.
Orange.—Golden Glory, Robert Sydenham.
Orange Cerise.—Fiery Cross.
Orange Pink.—King Alfred.
Orange Scarlet.—President, Thomas Stevenson.
Picotee (cream ground).—Jean Ireland, Mrs C. W. Breadmore.
Picotee (white ground).—Elsie Herbert.
Pink (deep).—Countess Spencer, Hercules.
Pink (pale).—Elfrida Pearson, Mavis.
Purple.—Royal Purple.
Rose.—Old Rose, Rosabelle.
Salmon.—Barbara, Melba.
Scarlet.—Red Star, Scarlet Emperor.
Striped.—Loyalty (blue), Phyllis (orange), Senator Spencer (maroon).
White.—Edna May, Etta Dyke, Nora Unwin, Stanley Crisp.
White (black-seeded).—Constance Hinton.—T. H. D.

NEW VARIETIES.

The following is a list of some of the best :—

Adelaide.—Purple, heliotrope, and blue flowers.
Alex. Malcolm.—Orange-scarlet flowers.
Annie Ireland.—White, picotee-edged flowers.
Brilliant.—Cherry-red flowers.
Brocade.—Orange and rose flowers.
Charity.—Rich crimson flowers.
Crimson Queen.—Rich crimson flowers.
Dobbie's Maroon.—Rich dark maroon flowers.
Doris.—Carmine-cerise flowers.
Edith Cavell.—Cream-pink flowers.
Elegance.—Silvery-pink flowers.
Faith.—Lavender flowers.
General Townsend.—Rosy-mauve flowers.
Gladys.—Mauve flowers.
Hawlmark Maroon.—Rich maroon flowers.
Hawlmark Pink.—Pink and rose flowers.
Hope.—Soft rose flowers.
Ian Hamilton.—Scarlet-cerise flowers.
Ivorine.—Ivory-white flowers.
Ivory King.—Ivory flowers flushed with cream.
Jack Cornwall, V.C.—Deep violet-blue flowers.
John Porter.—Bright orange flowers with rose wings.
Lady Hunter.—Salmon-buff or apricot flowers.
Liberty.—Orange flowers.
Lord Kitchener.—Intense scarlet flowers.
Market Pink.—Cream-ground pink flowers.
Mascott's Scarlet.—Glowing scarlet flowers.
Mascott's White.—Pure white flowers.
Mrs G. W. Bishop.—Cerise flowers.
Mrs Hitchcock.—Salmon-pink or cream flowers.
Mrs Tom Jones.—Delphinium blue flowers.
Orange King.—Orange flowers.
Palestine.—Cream-pink on lemon ground flowers.
Peace.—Soft pink flowers.
Royalty.—Purple flowers.
Tea Rose.—Pale creamy-buff flowers.
Valentine.—Soft pink on white ground flowers.
Victory.—Rosy-lavender flowers.
Warrior.—Chocolate-maroon flowers.

W. J. C.

SWEET PEPPERBUSH (*Clethra alnifolia*).—See SHRUBS.

SWEET SCABIOUS (*Scabiosa atropurpurea.* Nat. Ord. Dipsaceæ).—This plant is variably described as a hardy annual or perennial. It is much grown as an annual by sowing the seeds in heat, during March, and planting out the seedlings in May, when they flower freely from July till the advent of frost. If sown outside in April some flowers will be produced late in the season; but if sown in June or July the seedlings bloom the following summer like a biennial. The plants grow 2–3 ft. high (except the last in the list below), branch freely, and produce sweet-scented flowers on long stems, admirably adapted for cutting to place in water. A few varieties are named, but most are indicated by the colour. The double varieties are best; the single ones, available in many colours and averaging 2 ft. high, are seldom grown now.

Scabiosa atropurpurea.—Deep crimson. Height, 2–3 ft.

S. a. Azure Fairy.—Pale blue. Height, 2–3 ft.

S. a. Black Prince.—Dark purple or maroon. Height, 2–3 ft.

S. a. Pompadour.—Claret-purple, edged white. Height, 2–3 ft.

S. a. Scarlet King.—Fiery scarlet. Height, 2 ft.

S. a. Snowball.—Pure white. Height, 2–3 ft.

S. a. Tom Thumb or *Dwarf.*—Many colours. Height, 1–1¼ ft.

S. a. Yellow Prince.—Pale to bright yellow. Height, 2½ ft.

All the above will bloom freely from July to October.—J. F.

SWEET SEDGE, or MYRTLE GRASS (*Acorus Calamus*).—See *ACORUS* and *MEDICINAL HERBS.*

SWEET SULTAN (*Centaurea Moschata.* Nat. Ord. Compositæ).—This has been greatly improved

during recent years, and the newer giant-flowered strain has practically pushed the old type out of the garden. The *Imperialis Section* is probably also a large-flowered strain evolved on similar lines. It has been stated that these have been obtained by crossing *Centaurea Moschata* with *C. Margaritae*, but the latter is now referred to *C. Moschata alba*. *C. suaveolens* has also been suggested as a parent of the newer forms, but this too is a synonym of *C. Moschata*, so the inference is that these beautiful garden plants have been evolved by selection and varietal crossing from *C. Moschata*.

There is great colour range in Sweet Sultans. This extends from pure white to yellow and purple. The long-stemmed flowers, many of which are 3 ins. across, are charming for floral decorations, as they last a long time when cut. They may be raised in the usual way for hardy annuals by sowing out of doors in the autumn or spring. Good named sorts are: *Bridesmaid* (lemon-yellow); *Honeymoon* (bright yellow); *The Bride* (pure white); and *The Bridegroom* (rose-pink, with white centre).

SWEET VERBENA (*Aloysia citriodora*[1]).—See *ALOYSIA*.

SWEET VIOLET (*Viola odorata*).—See *VIOLA SPECIES*, *VIOLETS*, and *WATER GARDEN: PLANTS FOR THE*.

SWEET WILLIAM (*Dianthus barbatus*).—See *DIANTHUS*, and below.

SWEET WILLIAM (*Dianthus barbatus*. Nat. Ord. Caryophyllaceæ).—Though strictly perennial, the Sweet William gives the best results when sown in a cold frame, or outdoors in May or June, transplanted into a nursery bed and put into the flowering position in autumn. Choice varieties may be propagated by layering, cuttings, or division of the roots. When over, the old plants may be removed to a nursery bed, and their places in the beds taken by China Asters or early-flowering Chrysanthemums. The best varieties include:—

Dianthus barbatus Auricula-eyed.—White, zoned with dark colours, white eye, flowering June to July. Height, 1½ ft.

D. b. Harlequin.—Several colours on the same truss. A sort blooming from June to July. Height, 1½ ft.

D. b. magnificus.—A useful double crimson sort, flowering in June and July. Height, 1 ft.

D. b. Sutton's Pheasant's Eye.—Rich crimson, with white eye, flowering June to July. Height, 1½ ft.

D. b. Sutton's Pink Beauty.—Salmon-pink, flowering June to July. Height, 1½ ft.

D. b. Sutton's Scarlet.—Bright scarlet, flowering June to July. Height, 1½ ft.—J. F.

NEW VARIETY.

Scarlet Beauty.—This bears dense heads of bright scarlet flowers having a lighter coloured eye.

SWEET WOODRUFF.—See under WOODRUFF in *MEDICINAL HERBS*.

SWINE'S SUCCORY (*Hyoseris foetida*). See *HYOSERIS*.

SWISS KNAPWEED (*Centaurea Rhaponticum*).—See *CENTAUREA*.

SYCAMORE (*Acer Pseudo-platanus*).—See *TREES*.

SYCAMORE LEAF BLOTCH.—See *DISEASES OF PLANTS*.

SYMPHORICARPUS.—For the best species see *SHRUBS*.

SYMPHYTUM (COMFREY. Nat. Ord. Boraginaceæ).—This is a genus of somewhat coarse-growing tuberous and herbaceous plants, more useful in the wild garden than for the borders, though some favour their use for the last-named purpose,

[1] At Kew *Aloysia citriodora* is referred to *Lippia citriodora*.—EDITOR.

perhaps on account of their extensive flowering period, which lasts for three or four months. Where space is precious, however, there are, we must confess, many better things, and in that case little attention need be paid to the genus.

Culture.—Not the smallest difficulty will be found in growing these plants if a light soil and a somewhat severely shaded situation be found for them. Paxton says they will do well under trees; we have not tried this situation, but intend to. Propagation is also easy, the best mode of increase being to divide the roots in the autumn or spring, at which times they may be most successfully planted.

What to Grow.—The following are particulars of those which are of very easy culture:—

Symphytum asperrimum.—This is the well-known FORAGE COMFREY, bearing red and blue flowers in July, and growing about 6 ft. high. It is not a plant of much value in the garden.

S. caucasicum.—This is a pretty pale blue sort flowering in June, and growing 3–5 ft. high.

S. officinale (COMMON COMFREY).—This, with its tuberous roots, and white or red flowers in June, on plants 4 ft. high, is not of much value for the garden. It is, however, a valuable medicinal plant. (See COMFREY in our article on *MEDICINAL HERBS.*)

S. orientale.—This is a useful white sort blooming in May and June. It grows about 1 yd. high.

S. tuberosum.—As its name implies, this is a tuberous-rooted sort. It bears quite attractive yellowish flowers in June and July, on plants 3–5 ft. in height.

SYNDESMON.—Now included in the genus *THALICTRUM.*

SYNTHYRIS (Nat. Ord. Scrophulariaceæ).—A genus of low-growing plants, only two of which are worthy of cultivation. These species will thrive in sandy loam, in half-shady positions in the rock garden, and are propagated by division of the roots in the autumn.

Synthyris pinnatifida.—A rich purple-flowered sort, blooming in the summer. Height, 9 ins.

S. reniformis.—A sort with rich violet flowers, blooming in April and May. Height, 4 ins.

SYPHON GOURD.—See *ORNAMENTAL GOURDS.*

SYRENIA (Nat. Ord. Cruciferæ). Only one species of this genus, namely, *Syrenia sessiliflora* (Syn. *S. Lamarckii*), is at all generally grown. This is a hardy, yellow summer blooming biennial useful for the herbaceous or mixed border, as it grows about 1½ ft. high. It will succeed in common garden soil under the treatment usually given to hardy biennials, and is best propagated by sowing seeds in the usual way.

SYRIAN JUNIPER (*Juniperus drupacea*).—See *TREES.*

SYRIAN RUE (*Peganum Harmala.* Nat. Ord. Rutaceæ).—This is distinct from the RUE mentioned in our articles on *POTHERBS* and *RUTA.* It is a hardy herbaceous perennial of the easiest culture, bearing white flowers from June to July on plants 12 ins. high, but, unless the collection is a large one, may be dispensed with.

SYRIAN TOBACCO (*Nicotiana rustica*).—See *TOBACCO PLANT.*

SYRINGA.—For the best species see *SHRUBS.*

SYRINGES.—See *GARDEN APPLIANCES.*

SYRUP FOR FRUIT PRESERVING.—See under BOTTLING IN SYRUP in *FRUIT BOTTLING AND PRESERVING.*

TABLES.—See *GARDEN FURNITURE.*

TACSONIA (PASSION FLOWER. Nat. Ord. Passifloraceæ).—This is a free-flowering greenhouse climber, and most suitable for covering the roof of the greenhouse or conservatory. It is propagated by cuttings of half-ripened shoots in the summer, inserted in sandy soil under a frame or hand-light. Pot for success in good fibrous loam, peat, leaf-mould, and sand. Temperature required, 40–45° F.

Greenhouse Species and Varieties.—*Tacsonia exoniensis.* — Sepals and petals brick-red, rose-pink within, violet throat. Flowers from July to August. Height, 3–15 ft.

T. ignea.—Scarlet. Flowers from July to August. Height, 3–15 ft.

T. insignis.—Crimson. Flowers from July to August. Height, 3–10 ft.

T. mixta.—Pink. Flowers from July to August. Height, 3–15 ft.

T. mollissima. — Rose. Flowers from July to August. Height, 3–15 ft.

T. Van-Volxemii. — Crimson. Flowers from July to August. Height, 3–15 ft.

TAGETES.—See *MARIGOLD.*

TALL JUNIPER (*Juniperus excelsa*) and **TALL SILVER FIR** (*Abies grandis*). See *TREES.*

TAMARACK (*Larix pendula*).—See *TREES.*

TAMARISK.—The genus TAMARIX.

TAMARIX.—For the best species see *SHRUBS.*

TAN.

This, also known as TANNERS' REFUSE, consisting as it does almost entirely of bark, is of very little value to the gardener. It only rots down very slowly, and while free from objectionable properties, it should never be used if other material is available. Where, however, the supply is large, a quantity of the tan may be thoroughly saturated with slops as strong as possible, and after being mixed with a small proportion of other vegetable matter, it may be stacked in a heap for six months. If some further strong slops can be poured over the heap every week, by the end of that period some manure of fair quality should be produced for use at the rate of 3 cwt. per sq. rod.

TAN BARK OAK (*Quercus densiflora*).—See *TREES.*

TANACETUM (Nat.Ord.Compositæ). This is an unimportant genus of hardy herbaceous perennials. The best known species is the COMMON TANSY (*T. vulgare*), the culture of which is briefly covered under *MEDICINAL HERBS.* Some of the dwarfer species may be used for the rougher portions of the rock garden, but these are not of sufficient importance to warrant us describing them here.

TANGIER PEA (*Lathyrus tingitanus*).—See *LATHYRUS.*

TANKS: CAPACITY OF.—See CAPACITY OF TANKS OR BOXES under VOLUMES in *ARITHMETIC AND GARDENING.*

TANKS or CISTERNS.

These are made in various sizes and patterns. They are useful for holding water and liquid manure, and more so than tubs or barrels on account of holding a far larger quantity. Galvanised iron tanks and leaden cisterns are the best, as they are rust-proof. A tank should be put in each separate portion of the garden and water laid on. There should be a fair

sized cistern or tank in each greenhouse, in order that the water may become the temperature of the house before use.

TANNED NETTING.—See *GARDEN NETTING.*

TANNERS' REFUSE.—See *TAN.*

TANSY.—See *MEDICINAL HERBS.*

TANSY-LEAVED THORN (*Crataegus tanacetifolia*).—See *TREES.*

TAP-ROOTED CROPS.—See *KINDS OF CROPS.*

TAR.—See *SOIL FUMIGATING.*

TARAXACUM (Nat. Ord. Compositæ).—This is a small genus of weedy tap-rooted herbaceous perennials, the best known of which is the COMMON DANDELION (*T. officinale*, of which a synonym is *T. ceratophorum*). Its uses are described in our articles on *MEDICINAL HERBS* and *SALAD PLANTS*, while its grosser aspect is considered in our article on *WEEDS*. The other two species grown at Kew are not of sufficient importance to be mentioned here.

TARE.—See *VICIA.*

TARRAGON.—See *ARTEMISIA* and *POTHERBS.*

TARRED NETTING.—See TANNED NETTING in *GARDEN NETTING.*

TASSEL FLOWER (*Emilia.* Syn. *Cacalia.* Nat. Ord. Compositæ).—This quaint little plant is found hiding occasionally in catalogues under the name of *Cacalia coccinea*, but its correct title is *Emilia flammea* (Syns. *E. coccinea, sagittata*, and *sonchifolia*). In either case the specific name suggests the brilliant orange-scarlet colour of the small blossoms, which are clustered in such a way as at once to suggest the aptness of the name of Tassel Flower. Although an Indian plant, it is quite hardy, and will stand the winter if sown in early September, but an April sowing will prove successful provided the seedlings are transplanted while quite small, root disturbance being resented at a later period. Although not one of the most effective of annuals in the garden, the Tassel Flower is well worth cultivating on account of its novel appearance, and its usefulness for floral decoration when cut.

TASSEL HYACINTH (*Muscari comosum*).—See *GRAPE HYACINTHS.*

TAXODIUM.—For the best species see *TREES.*

TAXUS.—For the best species see *TREES.*

TEA-LEAVED WILLOW (*Salix phylicifolia*).—See *TREES.*

TEA ROSES.—See HYBRID TEAS under ROSES FOR EXHIBITION in *ROSES FOR ALL PURPOSES.*

TEASEL.—See *DIPSACUS.*

TEASEL GOURD.—See *ORNAMENTAL GOURDS.*

TEASEL-HEADED CLOVER (*Trifolium maritimum*).—See *TRIFOLIUM.*

TECOMA (Syn. *Bignonia.* Nat. Ord. Bignoniaceæ).—This includes several beautiful free-flowering climbers, most suitable for rambling over the rafters of a greenhouse. They are propagated by cuttings of ripened shoots taken in autumn in sandy soil under frame or bell-glass with slight bottom heat, and should be set in good loam, peat, and sand. Temperature needed, 40–50° F.

Greenhouse Species :—*Tecoma capensis.*—Orange-scarlet. Flowers in August. Height, 2–10 ft.

T. Cherere.—Orange. Flowers in July. Height, 2–10 ft.

T. grandiflora.—Orange. Flowers in July. Height, 2–10 ft.

T. jasminoides.—White streaked red. Flowers in August. Height, 3–15 ft.

T. radicans.—Orange. Flowers in July. Height, 2–10 ft.

T. speciosa.—Pink shaded purple. Flowers in August. Height, 2–10 ft.

TEESDALIA.—See *PEPPER CRESS.*

TEFF (*Poa abyssinica*).—See *POA.*

TEINTURIER GRAPE (*Vitis vinifera purpurea*).—See *CLIMBING AND TRAILING PLANTS.*

TELEGRAPH PLANT (*Desmodium canadense*).—See *DESMODIUM.*

TELEKIA.—Now included in the genus *BUPHTHALMUM.*

TELEUTOSPORE PHASE.—See *RUST FUNGI.*

TELLIMA (Nat. Ord. Saxifragaceæ).—Only two species of this pretty genus are generally grown. These, *T. grandiflora* and *T. parviflora,* are hardy herbaceous perennials, the former bearing greenish flowers just tinged with pink, and the latter white flowers in April and May, on plants 12 ins. high. They are useful alike for the perennial and rock border, or in the rock garden itself. Their cultural requirements are the same as those of *MITELLA,* on which we devote a separate article.

TEMPERATURE REQUIRED FOR GERMINATION.—See *GERMINATION OF SEEDS.*

TEMPERATURES FOR STERILISING FRUIT.—See *FRUIT BOTTLING AND PRESERVING.*

TEMPORARY HARDNESS.—See *WATER: TO SOFTEN.*

TENCHWEED (*Potamogeton natans*). See *POTAMOGETON.*

TENDRILLED TRUMPET FLOWER (*Bignonia capreolata*).—See *CLIMBING AND TRAILING PLANTS.*

TENTS.—See *GARDEN FURNITURE.*

TENURE: Security of, for Small Gardeners.—What does Security of Tenure mean to the small gardener? It means more interest, and greater scope for the production of food. In the first place, when a man gets an allotment, as a rule, he does not trouble about the terms he gets it on, but when the time comes for him to think about putting up some kind of a structure, in which to keep his tools, seeds, and other gardening commodities, he has a talk with his pal or next garden neighbour, makes known his plans for building a greenhouse or substantial hut, and then his friend advises him to do nothing of the kind, pointing out the clause in the terms of agreement, which states that six months' notice on either side shall terminate the contract. Now, as a rule, the greenhouse and hut scheme is abandoned, and a nondescript sort of place is erected, as a rule made out of a couple of egg or bacon boxes just large enough to hold the tools. Everything else in connection with the allotment, such as hedges, paths, gate, and water-tubs, is dealt with on the same lines, in fact, a "don't care" style is adopted. Under such conditions as these, good cultivation is practically impossible; interest and ardour are damped; and the gardener is dissatisfied when, as he surveys his allotment, he finds it is not as he intended it to be: his object has been defeated by his not having *Security of Tenure.* And when the bad weather sets in, and as a rule it does in late autumn, he neglects to come to his allotment, as he knows he has no place of shelter in the event of rain or snow. Consequently the vacant ground does not get trenched, or dug, as it ought to be, nor do the growing crops get the attention which is necessary at this time of the year to assist them in battling through the winter. All the time lost during the autumn and winter months is fatal the following year, as the work of trenching has to be done in the spring, as soon as the soil is in a fit condition, which means delay in planting and seed sowing, as the soil is not, as a rule, in a fit condition to plant or sow immediately after trenching. This accumulation of work generally leads to mistakes which are not observed at the time, and subsequent failure of the crops, which means loss of food, and this at any time certainly ought to be avoided.

Now, on the other hand, had this man

been granted "Security of Tenure" in the first place, the greenhouse or substantial hut would have been erected. Interest would have been aroused, and his wife, who will play no small part in assisting him, would set to work at once, and make the interior of the hut nice and comfortable. She would also offer suggestions as to the making of paths, planting the hedges, position of the gate, etc. This is a good start, and augurs well for the future. With nothing to fear as regards eviction, he is not afraid to spend a few extra shillings in making his allotment look smart, neat, and a pleasure to behold; his wife again will take great delight, accompanied by the kiddies, in bringing her husband's tea to the allotment on Saturday afternoon, when he can take it in comfort in the hut, instead of having to walk home, which perhaps is some distance, thereby saving time, and this is very precious to the amateur. Then again he can come straight from work to the allotment, change his boots and clothes in the hut, and commence work at once instead of having to go home first. All these little time-savers may appear of no importance to the onlooker, but they mean a great deal to the amateur who has Security of Tenure. A man under these conditions is comfortable, and his enthusiasm knows no bounds; everything comes quite easy and natural; his crops grow apace, and are a decided success; and when the winter comes he does not mind the weather, as he knows he has a good shelter in the event of a shower. He can always find a job to do in the hut during bad weather, and as soon as conditions are favourable again, he can get on with his trenching or digging. By the time winter sets in he has got all his vacant land dug, and, subject to the frosts and drying winds, it will be in fine condition for planting and sowing when the time comes. It is obvious that the cultivation of the allotment under these conditions will ensure heavy crops, which means more food.

Thus we have seen both sides of this question; on the one side the man hampered at every point through lack of Security of Tenure, and on the other the man helped and encouraged, and producing large quantities of food when given security. Is not this worth trying for? Yes. If so, then it is for every allotment holder to do his level best to get that Security which it is in the country's good that he should have.—J. P.

TERRESTRIAL ORCHIDS.—See under POTTING in *ORCHIDS: POTTING AND WATERING OF.*

TEST FOR AMMONIA COMPOUNDS. See *AMMONIA AND AMMONIUM COMPOUNDS.*

TESTACELLÆ.—See CARNIVOROUS SLUGS in *INSECT PESTS.*

TESTING SEEDS.—See *SEED TESTING.*

TETRAGONIA (Nat. Ord. Aizoaceæ).—This is a genus of annuals requiring to be raised in heat, and hardened off prior to planting outside in rich loam. *T. crystallina* is known as the ICE PLANT, but must not be confused with *Mesembryanthemum crystallinum*, also known by that name, and as the COMMON ICE PLANT (see article on *MESEMBRYANTHEMUM*). *T. expansa* is the vegetable known as NEW ZEALAND SPINACH, the culture of which is dealt with under *SPINACH.*

TETRAGONOLOBUS.—Now included in the genus *LOTUS.*

TETRANYCHUS.—See RED SPIDERS in *INSECT PESTS.*

TETRAPOMA.—Now included in the genus *NASTURTIUM.*

TEUCRIUM (GERMANDER. Nat. Ord. Labiatæ).—A large number of species of this genus have been described, including hardy herbaceous perennials, hardy evergreens, half-hardy or greenhouse herbaceous and tender greenhouse evergreens. In the present notes we confine ourselves to a few of the best hardy evergreen and hardy herbaceous perennials which may be treated as border or rock plants. These are of easy culture, and thrive in ordinary, light garden soil in a sunny site, though in cold districts they often do not survive our winters unless transferred to a frame. They can be propagated in the usual way by summer-sown seeds or spring division of the roots, and spring planting is recommended.

What to Grow.—Some of the following were greatly valued for medicinal purposes in the olden days, and indeed are used still, chiefly as emmenagogues, and for obstructions, etc., in the kidneys :—

Teucrium Arduini.—This bears yellow flowers in July, and averages 1½ ft. in height.

T. aureum.—Syn. *T. Polium*, which see.

T. Botrys (JERUSALEM OAK).—This bears red or reddish-purple flowers in August. It is a biennial or short-lived perennial about 12 ins. high.

T. Chamaedrys. — This is the COMMON GERMANDER, hardly worth growing where space is precious. It bears purplish flowers in July or August, and grows about 9–12 ins. high.

T. flavum.—This bears yellow flowers in August, and averages about 1 yd. in height.

T. Marum (CAT THYME).—This bears light, lilac-purple flowers in July and August, and grows 1½–2 ft. in height.

T. multiflorum.—This is one of the best sorts, bearing as it does pale red flowers in August. It grows about 12 ins. high.

T. Polium (Syn. *T. aureum*).—This is popularly known as POLY GERMANDER, but is perhaps more suitable for the wild garden, where space in the border is precious. It bears pale purple flowers from August onwards, and averages 12 ins. in height.

T. pyrenaicum.—This is more useful in the rock garden than in the perennial border, though a little tender in most districts. It bears creamy-white flowers from June to July, and grows about 6 ins. high.

T. Scorodonia.—This is the well-known WOODSAGE, which see under that name in our article on *POT-HERBS*. It is more suitable for the herb border or kitchen garden than for the perennial parterres.

See also *SHRUBS*.

THALICTRUM (MEADOW RUE. Nat. Ord. Ranunculaceæ).—These are both attractive foliage plants and noble flowering subjects for the hardy herbaceous or perennial border. They are exceedingly useful also for margins of shrub borders, for the wild garden in sun or light shade, and one, notably *T. alpinum*, is useful in the rock garden. The tall sorts are splendid for the back rows of borders, and the fern-like foliage of most of them makes the plants useful for additions to bouquets where Asparagus Fern or other foliage is not available. They succeed in ordinary light, rich, cool, sandy garden soil, doing best when this is enriched with vegetable matter instead of dung, and are not hard to propagate by division of the roots in the autumn or spring, at which last period planting may most successfully be carried out. A very large number of species have been described, and of them we recommend the following :—

Thalictrum adiantifolium.—Syn. *T. minus adiantifolium*, which see.

T. alpinum.—This is a useful dwarf sort for the rock garden bearing white or whitish-yellow flowers in June, and growing only 6 ins. high.

T. anemonoides (RUE ANEMONE).—This bears pretty white flowers in April and May, on plants 12 ins. high.

T. angustifolium.—This useful sort bears pale lemon-yellow flowers from June onwards, and grows 1 yd. high.

T. aquilegifolium.—This and its variety *atropurpureum* bear pale and dark purple flowers respectively in June and July, and have foliage much like that of the Aquilegia. Both average 1 yd. in height. The white variety *album* is very pleasing.

T. atropurpureum.—This nurseryman's sort is not a species but the variety *atropurpureum* of the above.

T. Delavayi.—This is a useful free-blooming light purple sort flowering from June to September, and averaging 3–7 ft. high.

T. dipterocarpum.—This useful sort bears rosy-purple flowers in July and August, on plants 3–6 ft. high.

T. flavum.—This, the COMMON MEADOW RUE, or MEADOW RUE, with its orange flowers in June, is not much grown, but may be planted in the wild garden, where it will grow about 4 ft. high.

T. glaucum (Syn. *T. speciosum*).—This is a useful sort bearing yellow flowers in June, and growing 5 ft. high.

T. majus.—This bears unattractive yellowish-green flowers in June, and is only useful in the wild garden. It grows 3–6 ft. high.

T. minus.—Nearly a dozen varieties of this yellow June flowering species are grown at Kew, all of them varying from 1–4 ft. in height. *T. minus adiantifolium* (Syn. *T. adiantifolium*) bears greenish-yellow flowers; *T. m. elatum* is a pale yellow sort; *T. m. purpurascens* is pale purple; and *T. m. saxatile* (Syn. *T. saxatile*) bears red and white blooms.

T. pratense.—Syn. *T. flavum* above.

T. purpurascens.—This bears pale purple flowers in June, and grows about 1 yd. high.

T. saxatile.—Syn. *T. minus saxatile* above.

T. sparsiflorum.—This nursery sort is probably a dwarf strain of *T. glaucum.* It bears yellow flowers in June, and grows about 3 ft. high.

T. speciosum.—Syn. *T. glaucum* above.

T. tuberosum.—This is a white tuberous-rooted sort flowering in June, and growing 1½ ft. in height.

THE OLD MAN'S CACTUS (*Pilocereus senilis*).—See *CACTI.*

THERISIA.—Now included in the genus FRITILLARIA. See *FRITILLARY.*

THERMAL CONSTANT.—See *GERMINATION OF SEEDS.*

THERMOMETERS.—See *FRUIT BOTTLING AND PRESERVING* and *GARDEN APPLIANCES.* See also *ARITHMETIC AND GARDENING.*

THERMOPSIS (Nat. Ord. Leguminosæ).—This is a small genus of hardy herbaceous perennials not very generally grown but deserving of more attention than has up to now been bestowed upon them. They succeed in light, rich, sandy soil and are best propagated by seeds sown in the usual way in the summer. In cold districts they do not winter successfully outside, and thus planting out of new stock should be delayed till mid-March. We recommend the following:—

Thermopsis barbata.—This bears purple flowers from June to July, and averages 1½ ft. in height.

T. caroliniana.—This is a useful sort bearing yellow flowers in June and July. It grows 1½ ft. in height.

T. lanceolata (Syn. *T. lupinoides*).—This is a useful yellow June blooming sort, growing 1–1½ ft. in height.

THIMBLE-BERRY (*Rubus occidentalis*).—See *SHRUBS.*

THIN SOWING.—See under GENERAL MANAGEMENT in *VEGETABLES: GENERAL CONSIDERATIONS.*

THINNING FRUIT.—See *FRUIT CULTURE, HARDY: GENERAL CONSIDERATIONS.*

THINNING OF CROPS.—See under GENERAL MANAGEMENT in *VEGETABLES: GENERAL CONSIDERATIONS.*

THISTLE.—See *CARDUUS* and *CNICUS.* See also COMMON SOW-THISTLE and CREEPING THISTLE in *WEEDS.*

THLASPI (BASTARD CRESS. Nat. Ord. Cruciferæ).—This is a large genus of hardy annual and peren-

nial cress-like plants hardly worth growing. The best known species is *Thlaspi arvense*, popularly called PENNY CRESS.

THORN.—A name applied to the genus CRATAEGUS. See *TREES*.

THORN APPLE.—See *DATURA* and *MEDICINAL HERBS*.

THREE-LEAVED NIGHTSHADE.—See *TRILLIUM*.

THREE-YEAR ROTATION.—See *ROTATION OF CROPS AND DOUBLE CROPPING*.

THRIFT.—See *ARMERIA*.

THRIFT PINK (*Dianthus Armeria*).—See *DIANTHUS*.

THRINCIA.—Now included in the genus LEONTODON.

THRIP or BLACK FLY.—See *INSECT PESTS*.

THRIPIDÆ.—See THRIP OR BLACK FLY in *INSECT PESTS*.

THROAT-WORT.—See *TRACHELIUM*.

THUNBERGIA.—For best species see *CLIMBING AND TRAILING PLANTS*.

THUNIA.—See *ORCHIDS*.

THUYA.—For the best species of this see *TREES*.

THYME.—See *POTHERBS* and *THYMUS*.

THYME-DODDER.—See *DISEASES OF ROCK PLANTS*.

THYME-LEAVED HAREBELL (*Wahlenbergia serpyllifolia*).—See *WAHLENBERGIA*.

THYMUS (THYME. Nat. Ord. Labiatæ).—This is a well-known genus of fragrant plants, which are easily grown on rocky banks or ledges, and are propagated by division of the roots in autumn or spring. The best species are :—

Thymus azoricus.—This is a diminutive shrub with evergreen leaves. Flowers purple. Site, half-shade. Soil gritty. Flowering Period, June to July. Height, 2 ins.

T. carnosus.—This is an erect-growing shrubby species with greyish leaves. Flowers white. Site sunny. Soil gritty loam. Flowering Period, August and September. Height, 9 ins.

T. Serpyllum (WILD THYME).—This is the well-known creeping plant with scented foliage. Flowers rose-purple. Site sunny. Soil gritty. Flowering Period, June to August. Height, 2 ins. There are numerous garden varieties of this.

For culture of Garden Thyme, see THYME in our article on *POTHERBS*.

THYROSTACHYS.—See *BAMBOOS*.

TIARELLA.—See *FOAM FLOWER*.

TICK TREFOIL.—See *DESMODIUM*.

TICKSEED.—See *COREOPSIS*.

TIDY TIPS (*Layia*. Nat. Ord. Compositæ).—It is difficult to understand how these plants came by this name. The hardy annuals, which are the most frequently grown, are of lowly growth, easy cultivation, and seem to be waiting for the skill of some patient cultivator to bring them into greater prominence and beauty. Garden soil of average quality suffices them, but to secure a long season of bloom two sowings should be made out of doors, one in April and one in September. We describe the three best species below :—

Layia Calliglossa (Syn. *Oxyura chrysanthemoides*).—This very free-blooming sort bears yellow flower-heads which are white-margined and golden-centred. It blooms all the summer, and grows 1 ft. high.

L. elegans.—This is of spreading habit. It produces yellow flower-heads throughout the summer, and grows 8 ins. high.

L. glandulosa (Syn. *L. neomexicana*).—This useful sort bears white flowers throughout the summer, and grows about 1 ft. high.

TIDYING UP.—See *AUTUMN GARDEN, THE*.

TIGER IRIS (*Tigridia*. Nat. Ord. Iridaceæ).—This is a pretty bulb, hardy only in the warmest districts, and thus is best taken up each autumn and wintered indoors. It may be

grown in pots in the cool greenhouse or in well-sheltered sunny borders of light rich soil, and may be propagated either by seeds or bulbils.

What to Grow.—We recommend the following which bloom from May to July, and average 12 ins. high; for full descriptions and extensive colour range bulb specialists should be consulted: *Tigridia Pavonia*,[1] the PEACOCK TIGER IRIS, *T. Pringlei*, and *T. violacea*.

TIGER LILY (*Lilium tigrinum*).—See *LILIES*.

TIGER MOTH.—See *INSECT PESTS*.

TIGRIDIA.—See *TIGER IRIS*.

TILIA.—For the best species see *TREES*.

TIME REQUIRED FOR GERMINATION.—See *GERMINATION OF SEEDS*.

TIME REQUIRED FOR VEGETABLE STERILISATION.—See *VEGETABLE BOTTLING*.

TIMOTHY (*Phleum pratense*).—See *PHLEUM*.

TIPULIDÆ.—See LEATHER JACKETS in *INSECT PESTS*.

TISSUES.—Notes on various kinds of PLANT TISSUES will be found in our article on *PLANT PHYSIOLOGY*.

TOAD.

This is the gardener's best friend, feeding on slugs and insects. It should be encouraged and protected instead of being banished from the garden as is so often the case.

TOAD FLAX (*Linaria*. Nat. Ord. Scrophulariaceæ).—These popular garden plants have double-lipped flowers which at once suggest the Antirrhinum or Snapdragon, to which they are related. Usually they are about 1 ft. high and free-flowering. The plants are useful for bedding or as marginal groups to larger subjects. Raisers have greatly improved some species, notably, *Linaria maroccana*, and produced several colour varieties. If flowers are needed over a long period, sowings should be made in autumn and in spring.

Annual Species.—*Linaria bipartita* (Syns. *L. caerulea, incarnata, speciosa*). — A purple, summer-flowering sort. Height, 1 ft.

L. maroccana.—An old garden plant with violet-purple flowers, and about 9 ins. high. Good garden forms are:—*Excelsior* (a strain with varying colours); *Golden Gem* (yellow); *Queen of Roses* (rose-carmine); *Snow Queen* (white); and *White Pearl* (white).

L. reticulata. — A purple and yellow sort, blooming freely in the summer. Height, 18 ins.

L. spartea (Syn. *L. juncea*).—A yellow sort, blooming in summer. Height, 12 ins.

L. tristis (Syn. *L. marginata*).—A brown and yellow summer-blooming sort. Height, 12 ins.

Perennial Border Species.—These are hardy herbaceous perennials, thriving in ordinary light sandy garden soil, and propagated by seeds, cuttings, and division at the usual times. Excluding those which are half-hardy, we recommend the following, most of which spread somewhat rapidly:—

Linaria dalmatica.—This useful sort bears yellow flowers from June to August, and grows 2 ft. high.

L. galioides.—This is a pretty blue July blooming sort about 18 ins. high.

L. purpurea.—This bears purple flowers from August onwards, and averages 12 ins. high.

L. repens.—This is a spreading species bearing purple flowers from July onwards, and grows about 1–2 ft. high.

L. vulgaris.—This is the common Toad Flax of the fields and woods, bearing yellow flowers in August, and growing 12–18 ins. high. Its

[1] There are a host of garden forms of this species.—EDITOR.

variety *Peloria* is also yellow, but its height rarely exceeds 12 ins.

Rock Garden Species.—Three are suitable for the rock garden. The perennial is propagated by division in the autumn or spring. The annuals may be raised from seeds sown in heat in March.

Linaria alpina.—A free-flowering tufted plant. Flowers rich purple and orange coloured. Site sunny. Soil gritty loam. An annual, flowering from June to September. Height, 3 ins.

L. origanifolia.—A trailing species with hairy leaves. Flowers violet with yellow throat. An annual, flowering in June. Height, 3 ins.

L. pallida.—A creeping perennial plant. Leaves zoned with white. Flowers purple. Site, half-shade. Soil moist. Flowering Period, May to September. Height, 6 ins.

NEW VARIETY.

Linaria dalmatica speciosa.—This bears bright yellow flowers, on long branching spikes.

TOAD LILY (*Tricyrtis.* Nat. Ord. Liliaceæ).—Only three species of this are generally grown. These, *T. hirta* (Syn. *T. japonica*), *T. macropoda,* and *T. pilosa* (Syn. *T. elegans*), bear white, yellow, and greenish flowers, usually marked with purple or red in September and October, on plants 1–2 ft. high. They are hardy only in the warmer parts of the British Isles, and are best grown as half-hardy bulbs in the cool greenhouse in colder districts, any light peaty soil being suitable. As there are many more beautiful subjects, where space is precious it should not be taken up with them.

TOAD RUSH (*Juncus bufonius*).—See JUNCUS.

TOADSTOOL.—A popular name for several species of poisonous fungi.

TOBACCO PLANT (*Nicotiana.* Nat. Ord. Solanaceæ).—Although it is not supposed to be permissible to grow more than a dozen tobacco plants in each garden in any one season, this rule is never enforced, since the authorities realise, if enthusiastic amateur gardeners who love their pipes do not, that tobacco growing in this country is not a profitable or successful undertaking at all. Recently one amateur wrote the writer saying he was proposing to turn the whole of his allotment into a tobacco field and grow his own, since he could not get what he wanted at the shops. Needless to say he was urged not to do so, since if tobacco is to be grown successfully a very much hotter climate than ours is required. However, if not grown for smoking, the plants should certainly be grown for garden or greenhouse decoration, and they may be treated in either of two ways: raised as half-hardy annuals and planted out, or grown as indoor plants in cool greenhouses.

Of sorts to grow *N. affinis* is the one most often listed. This, however, is the incorrect name of *N. alata,* the well-known white-flowered plant emitting a pleasing scent in the evenings during August and September. Hybrids are available in several colours, and the height averages 1½–3 ft.

Less useful sorts so far as English gardens are concerned include *N. rustica,* which is the SYRIAN TOBACCO, and *N. Tabacum* (Syn. *N. macrophylla*), the VIRGINIAN TOBACCO. From the leaves of these two plants the tobacco of our cigarettes, cigars, and pipes is made.

TOBACCO WASH.—See *INSECT PESTS: GENERAL METHODS OF DESTRUCTION.*

TODEA.—For the best species see *Ferns and Fern Gardening.*

TOFIELDIA.—See *False Asphodel.*

TOMATO (*Lycopersicum esculentum.* Nat. Ord. Solanaceæ). — The cultivation of the Tomato has extended enormously, and with suitable houses there is no difficulty in keeping up a regular supply all the year round. The difference in quality of fruits which are allowed to ripen on the plants is apparent to the most inexperienced. The first sowing should be made in January in a light compost, standing the pots in a nice light position near the glass. As soon as the seedlings are well through the soil, pot off singly into small pots, using equal parts of loam and leaf-mould, with a fair sprinkling of sharp silver sand. Pot off the plants again as soon as the roots are nicely through the soil, placing them later into well-drained 8- or 10-inch pots. Pot-culture is the best for early supplies, and also for supplying fruits from December to April. Use a stronger compost for the final potting, of three parts loam, leaf-mould, and a little sand and lime rubble. Above all, pot firmly.

Maintain a fairly dry and buoyant atmosphere, and fertilise the earliest flowers with a camel hair brush, also those grown on plants for winter supplies. Keep the night temperature in winter as near 55° F. as possible, and about 65° F. by day. Stimulants should not be supplied in any form until after the fruits are set, and nothing beats diluted liquid manure, or a light dressing of superphosphate. Ripe fruits may be expected at the beginning of May from seeds sown in January; sowings made after that date may be planted out in almost any kind of house, or potted on with good results.

Sow seeds the end of June and July for winter and early spring supplies, and encourage the plants to make a strong, sturdy growth by free ventilation until the first trusses of fruit are set.

Varieties.—There are so many good varieties, and new varieties are constantly being raised, that selection is difficult.

Carter's Sunrise for January sowing, and *Sutton's Winter Beauty* for July sowing, are hard to beat. Other good varieties are: Moneymaker, Kondine Red, Best of All, Bide's Recruit, Ailsa Craig, and Paragon. *Golden Queen* and *Sutton's Peach Blow* are handsome fruits, and well worth growing.

F. J.

TOMATO DISEASES.

There are a number of diseases which attack the Tomato, and these being of some importance we treat them in an article to themselves rather than include them in the article on *Diseases of Plants.* The avoidance of an overdamp house, and of overfeeding, and the maintenance of healthy growth by hygienic conditions are the best ways of preventing disease attacks, though at times with every care plants go under.—Editor.

Tomato Bacteriosis (*Bacillus solanacearum*).—Owing to its having been confused with "Stripe," a good deal of uncertainty exists as to the extent of this disease in Britain. In the shoots the symptoms are somewhat similar to Stripe, namely dark markings, but this is succeeded by a wilting which does not occur in Stripe. A soft rot is said to be produced in the fruit. It should be remembered, however, that bacterial decay of tomato fruits is very common, as bacteria are very easily introduced through wounds, insect punctures, etc. In these cases the decay usually takes place at the

apex of the fruit where the withered flower is apt to hang on. In the true bacteriosis the bacteria are present in the shoots, and are believed to pass through the stalk into the young fruits.

REMEDIES.—Little at present can be recommended. Affected shoots should be cut off and burned, and seed saved only from healthy plants.

Tomato Canker (*Mycosphaerella citrullina*).—A very serious disease, but local and on the whole rare. It is distinguished by the presence of white, often sunken patches on the stem of the plants, either at ground level or higher up. Wilting follows, and the plants usually die. Minute black spots (the fruits of the fungus and containing innumerable spores) are produced on the white patches, and hence the disease is readily spread by such agencies as insects, splashing of water, and handling. Cucumbers are also affected.

REMEDIES.—Affected parts should be carefully uprooted and destroyed by fire as soon as ever the disease is noted. Sturdy growth, induced by good cultivation and plenty of air, helps the plants in resisting attacks. Affected soil should not be used for Tomato or Cucumber growing unless thoroughly sterilised by steam or chemicals.

Tomato Leaf Rust (*Cladosporum fulvum*).—Most destructive to tomatoes under glass. Pale yellow patches appear on the upper surface of the leaf, and the under-surface becomes covered with a dull-brown, velvety mass of spores. These readily infect neighbouring plants, and the disease spreads with great rapidity.

REMEDIES.—Good ventilation and a dryish atmosphere are essential. Remove badly attacked leaves and apply a fine sulphur powder with a sulphurator. Burgundy Mixture may also be used. In very bad cases one or two side shoots should be encouraged so as to produce fresh foliage to assist in development of fruit.

Tomato Leaf Spot (*Septoria Lycopersici*).—A serious disease in America but rare and local in this country. It is characterised by the presence on the leaves of small, round dark spots which later become grey. From these spots spores are produced in profusion, which spread the disease. In Britain it has only been observed under glass, where it may cause much damage.

REMEDIES.—Little experimental work has been done in this country. Where the disease is liable to occur Burgundy Mixture or Bordeaux Mixture should be used as a preventive. When present the affected plants should be destroyed, and the remainder sprayed with a good fungicide to prevent as far as possible further infection.

Tomato, Potato Blight on.—See article on *POTATO BLIGHT*.

Tomato Sleeping Disease (*Verticillium albo-atrum* and *Fusarium Lycopersici*).—This, which is by far the most serious of all tomato troubles, often occurs in epidemic form and kills off in the big tomato-growing districts thousands of plants under glass. The fungi causing the disease enter the plants from the soil, probably through wounds on the roots or at the collar, and invading the woody tissues develop abundantly, blocking up the water-conducting vessels, and thus causing a "wilt" and sudden collapse. Plants affected in this way are past recovery as the tissues are thoroughly permeated with mycelium. Though Fusarium and Verticillium are the fungi most commonly found it is not impossible that other fungi may enter the plants through minute wounds and behave in the same way.

REMEDIES.—As the fungi causing Sleeping Disease occur in the soil, it is of the utmost importance that soil or manure containing the spores should not be used for tomato growing. All diseased plants should be removed by the roots and burned. Contaminated soil may be sterilised by heat or by the use of chemicals, but where new soil can be obtained it is best to employ it.

Tomato Stripe.—One of the most destructive of Tomato diseases. The cause is still obscure, hence it is impossible to prescribe remedies or even suggest preventive measures. The disease is characterised by dark streaks or discolorations on the stem which are visible externally; the leaves are also affected and the fruits blotched. No parasitic organism has yet been discovered as causing "Stripe," but the evidence, which so far points to its being contracted from the soil, is suggestive of a parasite. It is believed that Stripe is not communicated by the seed.—A. D. C.

TOMATO HOUSES.—See CUCUMBER AND TOMATO HOUSES in *GREENHOUSES AND FRAMES.*

TOMATO: OUTDOOR (*Lycopersicum esculentum.* Nat. Ord. Solanaceæ).—Whether this be regarded as a fruit or a vegetable, it is very certain nothing is more popular among all classes, hence the reason that even the cottager having no "glass" invariably finds room for a few plants, and though his effort may not always meet with the success expected, this is more often due to the lack of understanding important details than to the variety or even our most abused climate.

Culture.—For many years past we have grown these with great success against banks, fences, walls, or in the open garden, and certainly regard them as being one of the most profitable crops.

A start should be made with strong plants (raised as advised in a previous article) about the last week in May, selecting a sunny position where a fairly heavy dressing of manure has previously been dug in. Tread the soil extra firm before planting, and again after new roots and top growth have been made. Keep each plant to a single stem, removing all side shoots as they appear. Do not be too generous with the watering-pot, and on no account apply stimulants of any kind until each plant has set a fair amount of fruit.

In a dull season, nip out the top of the plant at the second leaf beyond the third truss of fruit and gather all fruits as soon as they approach the ripening stage. If this is not done many will crack. Avoid cutting away the leaves until the end of August, after which date, instead of taking off a whole leaf, take only half, allowing the remainder to stay until the middle of September.

Varieties.—The following are good: Early Morn, Evesham Wonder, First Crop, Ideal, Kondine Red, Moneymaker, and Victory.—F. R. C.

NEW VARIETIES.

Dobbie's Model. — This bears round, uniformly rich red fruit, in large trusses, and the flesh is very firm. It is an early sort, suitable for both indoor and outdoor culture.

Grove's Reliance.—This bears round, medium-sized bright scarlet fruit of high quality. In habit it is vigorous, short-jointed, and prolific. It is suitable both for indoor and outdoor culture.

Kitchener. — This bears flattish, round, and slightly corrugated, high, scarlet-red fruit of medium size, in large trusses.

Market King.—This bears round, medium and uniform sized fruit

of good shape, with firm flesh. It is a heavy cropping early variety, suitable alike for indoor and outdoor culture.

Orange Sunrise. — This is an orange-coloured variety of the well-known *Sunrise*, with all its good qualities.

Scarlet Beauty.—This bears large, smooth, round fruit, with firm, deep scarlet flesh and a little core, in heavy trusses. It is best grown under glass.

The Don.—This bears scarlet fruit of good quality. It is very precocious and prolific, but is best grown indoors.—W. J. C.

TOMATOES: POTATO BLIGHT ON.—See *POTATO BLIGHT.*

TOMMASINIA.—Now included in the genus *PEUCEDANUM.*

TOMTATO.

This is obtained by grafting tomatoes on potatoes. It bears tomatoes on its branches and potatoes at its roots, and is sometimes offered as a novelty in horticultural papers by nursery firms to unwary amateurs. Its practical value at present is *nil*, since tomatoes and potatoes of far better quality can be obtained by growing separate plants, and, candidly, we cannot commend this freak to readers at present.

TONGUE GRAFTING.—See under GRAFTING in *PROPAGATION OF PLANTS.*

TONK'S MANURE.

This is a most useful fertiliser for roses, regarded by some growers as indispensable to success. The formula has been published in many works, and our Dictionary would be incomplete without it, as although every experienced rose-grower knows how to make it, the majority of amateurs do not. The formula is:—

Sulphate of Iron	1 lb.
Sulphate of Magnesia	2 lb.
Sulphate of Lime	8 lb.
Kainit[1]	10 lb.
Superphosphate	12 lb.

A quarter of a pound of the mixture after each ingredient has been thoroughly incorporated with the rest is forked into each square yard of rose bed in the late winter, or in the spring after completing the pruning. It may also be used in the autumn or winter for the preparation of the borders at the rate of 12–16 oz. per cubic yard of soil.

TOOL HOUSE or SHED.—This is now no longer distinct from the *POTTING SHED*, on which we give a separate article.

TOOLS.—See *GARDEN TOOLS.*

TOOLS FOR PRUNING.—See *PRUNING ROSES AND SHRUBS.*

TOOTH CRESS (*Cardamine diphylla*). See *CARDAMINE.*

TOP-DRESSING.

The difference between a top-dressing and a mulch is quite a simple one. A top-dressing is put on for the purpose of increasing the richness of the soil below it, and also for the purpose of feeding the plants. A mulch is put on simply to conserve the soil's moisture, without any idea of feeding the plants.

Top-dressings, then, being used for a definite feeding purpose should be as rich as possible, but, of course, it is advisable to study the requirements of one's plants before applying them. Mild material such as very old hotbed manure, useful both for top-dressing and mulching, can never do any harm, but on the other hand certain non-ericaceous plants might be quickly killed by a

[1] Half a stone of Sulphate of Potash may be substituted for the Kainit at desire, but the material is then more suitable for spring application than for winter use.—EDITOR.

heavy top-dressing of peat, it being a case of one plant's food being another plant's poison.

Top-dressing Materials.—If, then, we keep in view the definite purpose of top-dressings, we find that there is a wide range of materials which are highly suitable, many more indeed than for mulching. For the less robust plants we have old hotbed manure, year-old lawn mowings, and year-old vegetable refuse for use as top-dressings. For stronger subjects we have eight-weeks-old farmyard manure, six-months-old cow-dung, year-old pig manure, year-old leaf-mould, fortnight-old grass mowings, year-old weathered sewage sludge, and many other materials. For ericaceous plants such as Heaths and Rhododendrons, we have peat for use as top-dressings. This is usually mixed in varying proportions with stable or farmyard manure.

The above may usually be considered suitable for spring and summer top-dressing, and fertilisers may also be used for this purpose, as will be described in a paragraph later on. For autumn top-dressing, however, much less rich materials are usually applied, such as half-rotted leaves, very strawy stable dung, or even cocoanut fibre refuse. The object of this form of top-dressing is generally different from the above, with the exception of peat for the Rhododendrons and Heaths. It is used, as a rule, to keep the various subjects warm and freer from moisture during the winter. It acts, indeed, as a kind of autumn or winter mulch.

Useful Top-dressings.—The following will be found useful mixtures for the varying purposes named :—

For Choice Flower Borders.—These require a mild top-dressing, and we recommend the following mixture :—

Old Hotbed Manure	2 parts.
Leaf-mould	1 part.

The material should be well mixed and applied with a fork in a layer about 1–2 ins. thick.

For Lawns.—Lawns often get bare by constant use, especially if games are played on them. The bare spots should be well raked with a sharp iron-toothed rake, and one or other of the following top-dressings applied. Grass seed should then be sown on the surface, well rolled in, and birds kept off by means of cotton. The first mixture is :—

Old Hotbed Manure	6 parts.
Rich Turfy Loam	6 parts.
Leaf-mould	3 parts.
Wood Ashes	1 part.
Silver Sand	1 part.

A cheaper mixture is made as follows :—

Rotted Vegetable Refuse	6 parts.
Turfy Loam	3 parts.
Sand	1 part.

Where moss is troublesome on lawns this should be thoroughly raked off first, and the patch dusted well with quicklime. Either of the above top-dressings may then be used before seed is sown.

For Pot Plants.—Top-dressings are indispensable in the culture of certain pot plants, such as Tomatoes and other gross-feeding subjects which are strong growers. It is somewhat difficult to recommend here any one or two mixtures as being the best, since much depends on the condition of the various subjects up to the time of application. However, the mixture below will be satisfactory for strong growers :—

Turfy Loam	8 parts.
Month-old Dung	6 parts.
Bonemeal	1 part.
Wood Ashes and Charcoal	1 part.
Proprietary Fertiliser	A dash.

For less robust pot plants it will be found that the above is too strong. The mixture below is recommended for these :—

Old Hotbed Manure	1 part.
Leaf-mould	4 parts.
Turfy Loam	4 parts.
Fertiliser	A dash.

Top-dressings for most pot plants should be put on in two or three relays, each of which should be rather less than 1 in. thick.

For Rhododendrons. — These and Heath-like plants will appreciate a top-dressing of the following mixture —:

Good Peat	6 parts.
Old Hotbed Manure	3 parts.
Leaf-mould	1½ parts.

A good thick layer of this will serve both as a mulch and as food for the plants, especially if much water is poured through it in dry summer weather.

For Rock Plants. — Varying top-dressings are recommended for these by different authorities. The following, however, is quite a useful mixture :—

Old Hotbed Manure	4 parts.
Leaf-mould	4 parts.
Sharp Sand or Grit	1 part.

This can be applied in the spring or autumn, and put round the plants, care being taken not to allow any to reach their centres.

For peat-loving rock plants it is advisable to use the following or a similar mixture :—

Old Hotbed Manure	2 parts.
Good Peat	4 parts.
Leaf-mould	2 parts.
Sand or Grit	1 part.

The sand may be increased for subjects which like a very light medium, and the mixture should be applied in the same way as the previous one.

For Roses.—See under Manure Top-dressings below. Tonk's Fertiliser, a good manure any one can make, can also be used with great success. See article on *Tonk's Manure*.

For Shrub Borders.—Where Rhododendrons and other ericaceous shrubs are not grown, the following mixture forms a useful top-dressing for shrubberies :—

Rough Turfy Loam	2 parts.
Old Hotbed Manure	1 part.
Leaf-mould	1 part.

This can be dug in in the spring, autumn, or winter, but is best spread on the top in the spring.

For Vines.—See under Manure Top-dressings below.

Chip Top-dressings. — Quite a distinct form of top-dressing is that known as the chip top-dressing, and it is highly useful for rock plants and moraine subjects. Varying proportions of limestone, granite, or other chips, and sand are recommended by rock garden experts, but a mixture of 1 part sand to 4 parts of chips seems about right. This is scattered freely over the surface of the garden or moraine, and is distinctly useful for securing porosity of the soil and at the same time preventing evaporation being unduly rapid. It should be remembered when using these chip top-dressings that certain plants like a top-dressing containing lime chips, but that certain other plants will not grow in soil which contains lime chips, or is top-dressed with them. Some of the more important of these lime-hating plants are mentioned in our article on *Lime-Haters*. The majority of rock plants, however, thrive in or near limestone soils.

Fertiliser Top-dressings. — A further class of top-dressings is found in those in which proprietary fertilisers form a part, and, of course, the compositiom of these top-dressings may vary very widely. It is difficult to advise the pro-

portions of old hotbed manure, leaf-mould, and fertiliser to use, as most gardeners have their own pet mixture, but a good general top-dressing suitable for late winter or early spring use may be made up as follows :—

Old Hotbed Manure	12 parts.
Leaf-mould	12 parts.
Riddled Wood Ashes	3 parts.
Old Soot	2 parts.
Bonemeal	1 part.
Proprietary Fertiliser	2 parts.

Proprietary fertilisers which consist largely of coal ashes or other similar useless material should not be used, but materials rich in true plant food will give satisfactory returns if used as top-dressings. A far richer material than the above is made as follows :—

Sand or Fine Soil	4 parts.
Proprietary Fertiliser	1 part.

This can be lightly scattered over the surface and either hoed or watered in.

Single fertilisers are often used as top-dressings ; for instance, Sulphate of Ammonia, Salt, Nitrate of Soda, and Superphosphate. These are all lightly scattered on the surface in the spring or early summer and either hoed or watered in. The proportions are given and the general uses of these fertilisers are described in other articles.

Certain other single fertilisers are useful for top-dressings in the autumn, notably Bonemeal, Kainit, Ground Bones, and others. The use of these is fully described elsewhere.

Manure Top-dressings. — For certain subjects, notably Vines, Roses, Peaches, Fruit Trees, and Asparagus, an annual top-dressing of dung is more or less essential. This dung as a rule should be moderately fresh, and about a fortnight old if it has been well made and not allowed to become dry or mildewed. On light soils cow manure is preferable to stable or farmyard manure, but in any case this should not be used fresher than twenty-eight days from its production, otherwise it will be too watery, and for indoor work the cow dung should first be dried on a tray over the greenhouse boiler and then thoroughly moistened with boiling water in order to kill the numerous soil pests. Out of doors this is not usually considered necessary, but if it swarms with grubs as cow-dung often does, a soil fumigant should be scattered on the ground before the top-dressing is spread. As a general rule these top-dressings are applied in the autumn, though some of us think they would do more good if put on in the spring. Bonemeal may be scattered on the ground immediately before applying the manure. A layer about 2–3 ins. thick makes a very ample top-dressing.

What Not to Use. — Certain materials are distinctly objectionable for use as top-dressings, and of these the most notable is road scrapings. Pond mud and drain mud, of course, are quite unsuitable, and the same remark applies to leaf-mould made from such materials as poplar and walnut leaves, which is a strongly acid pulp. Generally speaking, the materials described as being objectionable for mulching are also objectionable for top-dressing, though this does not apply to fertilisers or to such materials as sewage sludge, which last if reasonably weathered is one of the richest and best of all top-dressings. The remarks under preparations for mulching apply equally to top-dressing, since but little value will be obtained if top-dressings are applied to impenetrable soils.

Mixing Top-dressings. — Just a word in conclusion on the important matter of mixing top-dressings. The material should for most purposes be applied in a fine state, though comparatively coarse material may be used for top-dressing choice flower or herbaceous borders and also for shrubberies. In the mixing of such materials as manure, vegetable refuse, and leaf-mould, it is best to start first with the drier material and gradually rub in that which is more sticky. This, however, does not apply to powdery materials such as wood ashes and proprietary fertilisers, which should be mixed first of all with the next drier material. Thus, for instance, in the lawn dressing described above a start should be made with the loam. Into this is rubbed the leaf-soil, then the old hotbed manure is rubbed into that mixture, and finally, the two dry materials, having first been mixed together in a separate heap, are gradually incorporated with the heap containing the leaf-mould, loam, and manure. Two or three turnings of the top-dressing heap will be necessary to ensure even mixing, after which the material, if it is not to be used for the coarser purposes described above, should be rubbed through a ½-inch sieve. Some top-dressings, of course, will keep indefinitely, but those containing proprietary fertilisers soon deteriorate, and are best made fresh as required for use.—E. T. E.

TOP-DRESSING AND MULCHING OF FRUIT. — See *FRUIT CULTURE, HARDY: GENERAL CONSIDERATIONS.*

TOPIARY WORK.

The choosing of a site, and the landscape work in connection with the laying out of a Formal or Topiary Garden is a matter of some importance, and where possible the portion of the garden containing the clipped trees should be surrounded on one side at least by a terrace or other high ground, for nowhere is the work seen to such an advantage as when viewed from some point above the level of the trees.

If possible the terrace or high ground should be provided on the north side of the garden, but on no account should sun and light be excluded. The varieties of trees that adapt themselves to Topiary Work are few, and these revel in the full amount of sunshine. Thus every care should be taken to avoid shade of any kind, but at the same time shelter must be provided, for it is of almost as much importance as sun. The shrubs for the purpose include Holly, Yew, and Box; the two latter in preference to the former, since Holly is apt soon to become scraggy.

No Formal or Topiary Garden is quite complete without a well-clipped hedge or two, and some of these at least should be planted with Beech or Hornbeam, though the former should only be used for hedges, as it has a warm appearance in winter, and the beautiful green of the spring foliage harmonises with the darker green of the Yew and Box. Both the last are surface-rooting shrubs; therefore, beyond trenching the ground to a depth of about 2½ ft., soil preparation need not be seriously considered, since after attention in the way of top-dressings can be resorted to. But if the soil is of a deep rich nature containing lime or chalk, so much the better. The Yew is a gross feeding plant and quickly exhausts the soil. Therefore, as the trees grow, rich top-dressings must be applied to the surface to keep the growth healthy and vigorous. When the planting is being done, on no account overcrowd the trees, or in after years the garden will

give a stiff and heavy impression to the eye, which should be carefully avoided. No clipping or training of the trees should be resorted to until they reach a fair size, say about 5 ft. in height.

The variety of shapes into which Yew and Box can be trained are too numerous to mention here. Therefore every individual plant should be carefully considered and trained according to individual taste and to whatever shape the tree lends itself most. The Yew in particular is an easy subject to handle. Time and patience will achieve almost any desired animal, bird, letter, or shape.

Perhaps the most important period in a Formal or Topiary Garden is the clipping season, for during that period the utmost care and attention must be bestowed on each tree or hedge, and only skilled workmen employed. Not a single branch or twig should be out of place when the work is finished.

The Yew when left by itself is always a dull and sombre plant, and thus nothing should be left undone to make the garden bright and pleasing by the free use of brilliant flowering plants.

Foliage or flowering plants which under different circumstances would be considered beautiful objects are very little use among Yews. Whatever flowers are used in the Topiary Garden, nature should be allowed as far as practicable to have full sway with them. No stiff or formal bedding schemes are permissible here; among sculptured trees man is always striving against nature—never an easy adversary to fight.

Topiary Work although greatly neglected, and in many cases largely despised, has a future before it; of that we are certain, so long as the art is kept within reasonable limits and not foolishly overdone. By many modern gardeners it is always referred to as a monument of perverted taste, but we hope that this obviously unjust appellation may soon be withdrawn.—W. G.

TORAIA (*Ilex latifolia*).—See *HOLLY*.

TORCH LILY.—See *KNIPHOFIA*.

TORCH PINE (*Pinus Taeda*).—See *TREES*.

TORENIA.—See *ANNUALS, HALF-HARDY: LIST OF*.

TORMENTIL (*Potentilla Tormentilla*). See footnote to article on *POTENTILLA*.

TORMENTILLA.—Now included in the genus *POTENTILLA*.

TORREYA.—For the best species see *TREES*.

TORTRICIDÆ.—See ROSE GRUBS in *INSECT PESTS*.

TORTRIX.—See under ROSE GRUBS in *INSECT PESTS*.

TOWN AND CITY GARDENING.

In speaking of the possibilities of the town and city garden, it must be distinctly understood that reference is here made to populous and congested areas and where the whir of machinery is heard. It is a difficult matter to deal with town or city gardening without distinguishing between areas such as Bermondsey, Clapham, Highgate, Shoreditch (in London), and cities such as Exeter and Sheffield. What would thrive in Highgate and Exeter would fail utterly in Shoreditch and Sheffield. So we come to the conclusion that success or failure will be mainly regulated and governed—given, of course, intelligent culture—by the number of dwelling-houses and factories in the district. We must impress owners of town and city gardens, however, that it is quite possible to convert them into things of beauty, and then such gardens will add to the amenities of city life very appreciably.

It is true that much has been done in this direction during the past decade, but much remains to be done, that verdure, colour, and beauty may replace miscellaneous rubbish and rank weeds. After thirty years in the most congested parts of London, coupled with the inspection of thousands of town and city gardens, the writer feels that the most serious obstacle to success is the tendency to plant subjects that appeal to the cultivator, with total disregard to their suitability for the purpose. This, of course, soon spells disappointment in cities. Attention should be concentrated on plants that have clearly demonstrated their suitability and that can be relied upon to give a good account of themselves, not simply for a single season, but to increase in size and beauty year by year.

Happily the number of available subjects in trees, shrubs, and flowering plants is by no means small, as we shall show. Also a good number of town and city gardens are fairly spacious in character. We will now give some notes on the more important points in the subject.

Soil and Site.—Let us start with a word as to what by courtesy we will term soil in town and city gardens. Builders' refuse plays an important part in this, and where the top-spit and subsoil are of a clayey nature the bricks and stones only should be removed, leaving the lime rubble, etc., to improve the texture of the ground. On the other hand, where the soil is porous and coal ashes have been added, it is useless to plant until a layer of clay has been buried 2 ft. deep and a layer spread on the surface to become pulverized through exposure to frost. This should be supplemented by a heavy dressing of stable manure, and then splendid results are certain. Both clay and manure can usually be had free of cost from "the powers that be." In the absence of builders' rubble and where clay predominates, a liberal dressing of road sweepings, combined with early digging, will do all that is required. If a little new soil can be added from time to time (and this can often be had gratis during the excavations for buildings in adjacent areas), so much the better.

The site will govern to a great extent the subjects employed. Where King Sol is excluded for the greater part of the day, trees, shrubs, and ferns must predominate. The importance of overhead waterings must be emphasised, and it must be remembered that apart from dirt deposits, smoke, etc., the atmospheric moisture is infinitely less in congested areas than in the country. From late spring to early autumn, except when heavy rain is frequent, ply the hose overhead both morning and evening. Not less important is to avoid overcrowding. Err on the side of sparsity, and humour the plants by an approved artificial fertiliser throughout the growing season.

The Lawn.—What about the grass plot or lawn? A perfect sward can be had, provided the right kinds of grasses are used. For this purpose there is nothing to equal *Poa annua* and *P. nemoralis*. Like the poor, the first named is always with us, and we meet it everywhere; by the roadside, in every garden, and on every patch of waste land. The fact of the seeds of this species maturing in gradual fashion accounts for its prohibitive price; and readers are advised to sow seed of *P. nemoralis*, and to lift plants of *P. annua* from anywhere and reset them 18 ins. apart in the lawn. In preparing the ground dig in some animal manure, level, and roll if

possible. Then dress with sulphate of ammonia in spring, and with soot and lime in autumn. Bluff the lusty sparrow by a network of black cotton and give abundance of water in dry weather. In this way is secured that delightful feeling of elasticity which is identified with a perfect sward.

Trees and Climbers.—Speaking of trees, careful judgment must be used in their arrangement and disposition, otherwise the whole garden will be robbed of air, light, and sun. Other than in big gardens trees of large growth such as the Plane, Poplar, and Elm are not to be recommended. On the other hand, the Lombardy Poplar (plant in a cavity and deluge with water), the common Laburnum, the double-flowered Cherry (*Cerasus Pseudo-cerasus*), and the Almond (*Amygdalus communis*) are especially valuable, since they blossom with the same freedom as in the country. The Hawthorns (*Crataegus*) behave splendidly if the branches are thinned every alternate year, whilst *Cotoneaster frigida* gives us a fine crop of berries which do much to brighten the garden in winter. Eminently satisfactory are the Tree of Heaven (*Ailanthus glandulosa, Catalpa bignonioides aurea,* and *Paulownia imperialis*. The False Acacia (*Robinia Pseudacacia*), the Lady of the Woods, or Silver Birch (*Betula alba*), and the Mulberry are quite at home; these must find a place on account of their historic associations and character. In addition to these we have the purple-leaved Beech (*Fagus sylvatica purpurea*) and the Service Tree (*Pyrus Sorbus*).

The Lime and Sycamore should be left strictly alone on account of the leaves assuming a rusty appearance in early summer. As a shade tree, plant 12 ft. high standards of either the Weeping Elm (*Ulmus campestris pendula*) or the Weeping Ash (*Fraxinus excelsior pendula*).

The Lombardy Poplar (*Populus fastigiata*) also the Laburnum form capital arches in city gardens. The first named requires no support whatever. Plant in April 10 ft. high trees in pairs, bend over the tops and tie securely with soft string so as to form a stately arch, and within two months you will have a perfect article. *Polygonum baldschuanicum,* the Traveller's Joy (*Clematis Vitalba*), *Clematis Jackmani, Jasminum officinale, Lycium barbarum,* and the rampant *Ampelopsis quinquefolia* are all adapted for covering wire, or preferably artistic wood arches, fences, etc.

Shrubs.—What shall we say about shrubs? If the garden is a sun-bathed one, plant them sparingly, if a quantity of flowers are required. *Olearia Haastii* is invaluable, and, apart from its silvery grey leafage, it literally clothes itself with white flowers in its season. *Yucca gloriosa* and *Y. recurvifolia,* the Persian and common Lilac (*Syringa*), the Guelder Rose (*Viburnum Opulus*), *Weigela* (*Diervilla*) *amabilis Eva Rathke,* —encourage the basal growths and remove a portion of the flowered stems of last-named annually, —*Hypericum moserianum* and *H. elatum,* the Bladder Senna (*Colutea arborescens*), the Mock Orange (*Philadelphus coronarius*), the Common, Oval-leaved and Golden-leaved Privets (*Ligustrum*), the Broad-leaved Holly (*Ilex Hodginsii*) and Broad-leaved Box (*Buxus Handsworthii*), *Aucuba japonica, Euonymus europaeus,*—the last named must be clipped twice annually in May and mid-August, — *Hibiscus syriacus, Cornus aurea Spathi* and *C. sibirica,* the Gold and Silver Elders (*Sambucus argentea variegata* and *S. aurea*), *Dimorphanthus mandschuricus variegata* (Syn. *Aralia*), together with the

Flowering Currant (*Ribes sanguineum*), the Spanish Broom (*Spartium junceum*), the Venetian Sumach (*Rhus Cotinus*), and *Prunus Pissardi*, are all amenable to city life. Bring together a dozen plants of Golden Privet (*Ligustrum aureum*) and *Prunus Pissardi* to furnish a striking bit of colouring, but exclude the ornamental Bamboos as they are not adapted for our purpose.

Hardy Flowers.—The fact that the majority of hardy perennials do well should do much to bring about sustained interest and enthusiasm on the part of the city dweller, and although we cannot attempt the 12 ft. wide borders and very spacious effects, it is possible in many instances to arrange a 6 ft. wide colony on the sunny side of the garden.

As a background plant *Bocconia cordata, Campanula pyramidalis* in blue and white, *Doronicum Harpur Crewe, Eupatorium purpureum*, the Golden Rod (*Solidago Golden Wings*), *Helenium autumnale* and *superbum*, with the tall *Helianthus rigidus Miss Mellish*, and *H. maximus Rev. C. Wolley Dod*; Hollyhocks (*Althaea rosea*); Lupines; the tall Michaelmas Daisies (*Aster cordifolius, ericoides, Novi Belgii*, etc.); the tall perennial Larkspurs (*Delphiniums*),—with these remove the spikes as soon as their beauty is past, top-dress, and then a second crop will be promptly produced,—*Rudbeckia laciniata fl. pl.* with its sheaves of golden blossoms, and *Tritoma uvaria*.

In the central part arrange *Achillea Ptarmica The Pearl, Chrysanthemum maximum King Edward VII*, and *H. G. Moon*; *Coreopsis grandiflora*; Day Lilies (*Hemerocallis flava* and *H. aurantiaca major*); *Gaillardia grandiflora*; *Heleniums Bolanderi* and *Riverton Gem*; *Helianthus multiflorus Bouquet d'Or*; *Heliopsis scabra B. Ladhams*; *Œnothera fruticosa major* and *Œ. Youngi*; *Phlox*—any white kinds as the coloured varieties are a failure; *Scabiosa caucasica*; *Senecio clivorum, Sidalcea candida* and *Listeri, Statice latifolia, Stenactis speciosa*, the Sweet Bergamot (*Monarda didyma*); and *Tritoma nobilis*.

We have plenty of material for the foreground. All the Pyrethrums are a success. If given plenty of water and top-dressing after flowering they will throw up a first-rate second crop of bloom. Carnations, too, do well, and especially so the perpetual-flowering variety *Britannia*. Keep sparrows from them with black cotton or fruit-netting, and plant on slightly raised ground. In the case of border varieties, layer as early in the season as possible. Other foreground plants include: Aquilegias; Alpine Auriculas; *Campanula turbinata hybrida*; Double Daisies; *Genista pilosa*; the glorious *Geum Mrs Bradshaw*; Irises in variety; *Helenium cupreum* and *H. Hoopesii*; *Heuchera hybrida* and *H. sanguinea*; *Iberis gibraltarica*; dwarf Michaelmas Daisies (such as *Aster acris, Amellus bessarabicus, dumosus, ericoides, Ezma*, and *Gorgeous*); *Œnothera macrocarpa*; Pansies; Pinks (*Her Majesty* and *Mrs Sinkins*); *Potentilla Miss Willmott*; *Rudbeckia Newmani* (Syn. *speciosa*); *Sedum spectabile*; Snapdragons (*Antirrhinum majus*); *Statice incana*; *Thalictrum adiantifolium*; *Tradescantia virginiana* in variety, and Violas as an edging.

We can also enjoy the beauty and fragrance of Polyanthus and Wallflowers by planting imported plants in April, watering overhead twice daily until established.

Annuals.—Touching upon annuals, the majority are short lived.

Sweet Peas cannot be expected to attain a height in excess of 3 ft. *Calliopsis tinctoria atrosanguinea*, Clarkias, Godetias, Marigolds (both African and French), Mignonette, dwarf and climbing Nasturtiums—(*Queen of the Tom Thumbs*, with foliage of silvery variegation, is a splendid edging subject for city gardens)—the Night-scented Stock (*Matthiola bicornis*), *Phlox Drummondii*, Shirley Poppies, sweet-scented Tobacco (*Nicotiana affinis*), Sweet Alyssum, and Ten-week Stocks are the most desirable.

Sow thinly in April, thin when quite young, and grow between a few early Chrysanthemums and Dahlias to take their place later. All the early flowering varieties of the first-named flower, also the October varieties, are to be recommended. For Dahlias see the notes farther on in this article.

Bulbous Plants.—A lady connected with Royalty visited a public garden not a thousand miles from the Tower Bridge in the spring of 1913, and declared that the display was superior to that at Hampton Court, which comment should be sufficient evidence that spring-flowering bulbous plants are a success in city gardens. It should be explained, however, that in common with every other family of plants, a considerable number fail to thrive or blossom satisfactorily. With regard to Hyacinths, leave the double-flowered kinds strictly alone. The single kinds as a whole do well, but it is advisable to avoid delicate shades and pure white varieties. Especially fine are: *Charles Dickens*, *Czar Peter*, *Gertrude*, *King of the Blues*, *King of the Yellows*, *Norma*, and *Robert Steiger*.

Among single Tulips, plant *Bacchus*, *Cottage Maid*, *Duchesse de Parma*, *Joost Von Vondel*, *Keizer's Kroon*, *Proserpine*, *Thomas Moore*, and *White Vondel*.

Tulips (Double).—Of these plant *Blanche Hative*, *Gloria Solis*, *La Candeur*, *Vuaarbaak*, and *Yellow Tournesol*.

Charming effects are produced by planting these tulips thinly and arranging wallflowers in modern kinds, also the Bunch Polyanthus between them. Splendid too are the Darwin Tulips, and in each case the foliage should be allowed to mature before the bulbs are lifted. In this way fair results are obtained the second season, though deterioration is very rapid in city gardens.

The above remarks apply to bulbous plants generally, and what treasures we have in the more robust amongst Narcissi, such as *Emperor*, *Empress*, *Horsfieldi*, *Princeps*, *Sir Watkin*, whilst the *Phoenix* varieties are a huge success. A point of importance is to defer planting till mid-November, as we do not want the growths above ground in winter to be crippled by exposure for months to fogs and smoke.

Few bulbous plants lend themselves to naturalisation, but the Bluebell of our woodlands (*Scilla nutans*), Chionodoxas, Crocuses, flowering Snowflakes (*Leucojum vernum*), and *Scilla sibirica* all settle down to city life with a good grace. They are quite worthy of a place in a portion of the lawn (planted 4 ins. deep), but we must leave the grass strictly alone till the end of June. Gladioli bloom well for a season only, but even under the most liberal treatment the new corms seldom attain to flowering dimensions. The same applies to *Hyacinthus candicans*, the majority of Liliums, the Snowdrop, and the Spanish Iris. The Tiger Lily (*Lilium tigrinum*) and its variety

splendens, *L. candidum*, and *L. testaceum*, however, resolve themselves into permanent colonies. Such popular species as *Lilium album*, *auratum*, *lancifolium*, *roseum*, and *rubrum* behave splendidly for a season, and sometimes for two years. It is important that, with the exception of the Madonna Lily (*L. candidum*), the stems be covered to a depth of 6 ins. with either soil or manure, and this should be done when the plants are about 1 ft. high.

Dahlias.—Regarding these we may say they are *par excellence* for town and city gardens, with the exception of the single-flowered kinds, which never bloom profusely. If the side or lateral growths are removed in the case of Paeony-flowered and Cactus sections, a glorious display will be assured.

Do not arrange the plants in partially shaded positions, or in proximity to trees, or shrubs of large growth. Moisten the plants overhead in the late evening; this will act in a dual capacity, encouraging rapid growth and also doing much to keep that nocturnal pest the earwig at bay. It is superfluous to say that garden varieties—that is, free-flowering sorts which throw their flowers well above the foliage—must be selected. A short list of the very finest for our present purpose may be given:—

Cactus.—Britannia, Duchess of Marlborough, Edith Carter, Florodora, Hon. Mrs Greville, Lustre, Mary Purrier, Mrs Douglas Fleming, Mrs Forrester Paton, Mrs Landale, Sportsman, Star, Sweetbriar, Thomas Parkin, and Victory.

Collerette.—Diadem, Henry Farman, Maurice Rivoire, and Negro.

Decorative.—Brentwood Yellow, Jeanne Charmet, Kaiserin Augusta Victoria, Market Yellow, and Souvenir de Gustave Doujon.

Paeony-Flowered.—Colonel Cody, Geisha, Liberty, Pantaloon, Paul Kruger, Reynolds, Salome, and Queen Wilhelmina.

Pompon.—Admiration, Annie Holton, Bacchus, Douglas, Emily Hopper, Irene, Tommy Keith, and Virginia.

Bedding Plants.—Among summer bedding plants for city gardens, the following are excellent:—

Fuchsias.—Ballet Girl, Charming, Earl of Beaconsfield, Lyle's-Own, Mrs Marshall, and Rose of Castille. These are all perfectly happy in the open sunshine, in fact they fail to give a good account of themselves in shady spots.

Zonal Pelargoniums.—Crystal Palace Gem, Flower of Spring, Henri Jacoby, Mrs Levers, Paul Crampel, and Queen of Whites. *Ivy-leaved Pelargoniums*:—Galilee and Madame Crousse are far and away the best for our purpose.

Then we have Calceolarias (bronze and yellow varieties), Cannas, Celsias (if planted when plumes are showing), *Eulalia zebrina*, *Heliotropium President Garfield*, Kochias, Lantanas, and Marguerites, whilst *Centaurea candidissima*, *Cineraria maritima*, *Dactylis glomerata elegantissima*, and *Koniga maritima* form capital edging plants.

Roses.—Mention must be made of a few Roses which defy the unfavourable conditions of town and city life, and it should encourage the city dweller to know that in the unfavourable season of 1918, roses established in a garden five minutes' walk from the City of London made 8 ft. of growth as large as a man's small finger. The varieties to plant are:—*Albéric Barbier*, *Dorothy Perkins*, *Gruss an Teplitz*, *John Hopper*, *Margaret Dickson*, *Pride of Waltham*, and

Ulrich Brunner, as well as the old Cabbage Rose, crested Provence and *Rosa rugosa* varieties.

Afford very liberal treatment, giving a bushel of loam and manure to each plant. Dress frequently with an approved artificial stimulant, and prune severely each season. In addition to daily overhead waterings, apply abundance of water to the roots, giving liquid manure at least once a week from spring onwards. To combat the attacks of aphis use petroleum emulsion.

Fountains and Water Gardens.—It is rare indeed that one comes across anything in the shape of a water garden in city gardens, but at the same time fountains with spacious basins are often seen. *Acorus Calamus*, *Alisma Plantago*, Callas in summer, *Caltha palustris fl. pl.*, and *Acorus pseudo-acorus* will thrive therein.

Plants for Shady Corners.—In a shady corner arrange a varied bed for ferns and other shade-loving plants. In the background plant *Ailanthus glandulosa* and *Paulownia imperialis*—cut both down to the ground level each winter—also the False Acacia, *Colutea arborescens;* then a plant or two of *Aucuba japonica* and *Euonymus europaeus* may well come in, filling in with Funkias in variety, more especially *F. albo-marginata* and *subcordata;* Lily of the Valley; *Megasea cordifolia* and Solomon's Seal. Of ferns, choose the Hartstongues (*Scolopendrium vulgare*), the Lady Fern (*Athyrium Filix-fœmina*), and the Male Fern (*Lastrea Filix-mas*). Many other kinds are a partial success; but it is painful to see a plant struggling for existence, and therefore only those that really thrive should be grown. In May plant half a dozen Variegated Maize (*Zea gracillima variegata*) here and there, which will do much to enhance the beauty of the whole. Plant and peg down a few ivy plants in front of the whole to form a foot-wide belt.

Wall Plants.—In speaking of the clothing of house walls, it may be said that the meanest building is redeemed from mediocrity by the presence of florescence and verdure. It is equally true that it is a huge mistake to hide the detailed portions of buildings that possess architectural features of merit, and here subjects that are amenable to drastic pruning should be employed. For the walls facing north and east *Ampelopsis quinquefolia*, *A. Veitchii*, and *Hedera Hederacea*, as also *Lycium barbarum*, will give a good account of themselves. It is necessary, however, to support the ivy by nailing, as it seldom clings to the walls in congested areas. For the walls facing south and west we have *Clematis Jackmani*, the Passion Flower (*Passiflora coerulea*), *Polygonum baldschuanicum*, the Traveller's Joy (*Clematis Vitalba*), whilst *Jasminum officinale* is perfectly happy, and flings its delicious fragrance far and wide over many weeks in early summer.

Vegetable Culture.—It may be pointed out that it is quite possible to produce first-rate vegetable crops in city gardens, and with the exception of Runner Beans, which fail to fertilise, and drop 90 per cent. of their flowers in the bud state, both vegetables and salads grow apace and give good returns for the labour and time devoted to them. We have to bear in mind, however, that the cultural details are in some respects quite different from those which obtain in the country, and where the air is pure and free from chemical impurities. It is idle to plant cabbages in October in the usual way, as the combination of smoke and fogs will destroy them.

Imported plants have to be set in March. Again, to sow Lettuces and Onions in autumn with a view to a stock of plants for spring planting, spells wasted efforts and seeds. Further, it is mere waste of time, labour, and money to plant Broccoli and Cauliflowers which mature naturally during the winter and early spring (purple Broccoli included). Such plants never survive, or at any rate become consumptive wrecks, and are relegated to the rubbish heap. A very safe, and indeed the only advisable programme, is to confine your operations to crops which mature from spring to the end of November. Onions are essentially pure-air plants, but it has been clearly demonstrated in the most congested parts of London, that onion sets planted in ground rich in potash are capable of producing first-rate bulbs.

With regard to Potatoes, there is nothing to equal the variety *Midlothian* for our purpose; whilst the maincrop kinds are not worth attention in city gardens. In dealing with Turnips, sow for an early crop only, unless it is desired to have a supply of tops to serve as a wholesome vegetable. The Garden Swede, however, is a great success, and the same applies to the coarser Mangold Wurzels. Splendid roots have been produced during the past three years on allotments within five minutes' walk of the square mile known as London City, and it is superfluous to say they form capital food for rabbits during the winter months. French Beans, both dwarf and climbing, are a big success, and the same applies to Broad Beans.

Pests.—In view of the fact that aphis is vastly more troublesome in city gardens than in the country, and on the principle that prevention is better than cure, it occurred to the present writer two years ago to experiment with spraying the plants twice weekly, dating from the time they reached 6 ins. in height, and until they attained the required size. Result, the plants were maintained in a perfectly clean condition throughout. A good insecticide should be employed, applied by means of a fine-rosed can. Lastly, we may point out that both Celery and Leeks behave splendidly, and being covered with soil in winter, are not affected by smoke and fogs.

W. H. A.

[It should be noted that the names of the various subjects mentioned in the above article are those by which they are commonly known by gardeners, and do not necessarily correspond with the newer nomenclature of Kew.—EDITOR.]

TRACHELIUM (THROAT-WORT. Nat. Ord. Campanulaceæ).—Only two Tracheliums are at all generally grown. These, *T. caeruleum* (Syn. *T. azureum*), often known as the BLUE THROAT-WORT, and *T. rumelianum* (Syn. *T. rumelicum*), are hardy herbaceous perennials bearing blue flowers from July to August, and averaging 1–2 ft. in height. A useful white form of the first is also available. They succeed under ordinary border cultivation as described in our article on *PERENNIALS: GENERAL CULTURE OF*, and may be propagated by seeds, cuttings, and root division at the usual times. Planting is best postponed until mid-March in very exposed districts, as under such condi ions they lack absolute hardiness.

TRACHYCARPUS.—For the best species see *PALMS*.

TRADESCANTIA (SPIDER-WORT. Nat. Ord. Commelinaceæ).—This is a genus of pretty ornamental greenhouse foliage plants, suitable for hanging baskets, and hardy

herbaceous perennials, suitable for the flower borders. The first section is increased by cuttings or divisions in spring. The soil should be good, rich, fibrous loam, with a little peat and sand, and it should be well drained. Temperature required, 50–55° F.

Greenhouse Species. — *Tradescantia discolor.* — White - pink. Flowers in July. Height, 1–1½ ft.

T. paniculata. — Pink shade. Flowers in August. Height, 1 ft.

T. Warscewicziana. — Purple. Flowers in May. Height, 1–2 ft.

T. Zebrina.—Purple. Flowers in July. Height, 1 ft.

Perennial Border Species.—These are not difficult to cultivate in ordinary light, rich soil in the usual way for hardy perennials. They are best propagated by root division in the spring, which is also the best planting time. We recommend the following :—

Tradescantia congesta.—This bears pretty blue flowers from July onwards, and averages about half a yard in height.

T. virginiana (FLOWER OF A DAY).—This is quite the most popular species, and five varieties of it are mentioned in the *Kew Hand-list of Herbaceous Plants.* The type is a pretty blue, but it may be had in red, purple, and white as well. All the forms bloom from July to August, and average 1–2½ ft. in height.

TRAGOPOGON (Nat. Ord. Compositæ).—This is an unimportant genus of hardy biennial plants succeeding with but little care in ordinary good garden soil in a sunny position, and chiefly propagated by seeds. *T. pratensis,* known as GOAT'S BEARD, is sometimes grown in the borders, and bears yellow flowers from May to July, on plants 1½ ft. high. The best known species, however, is *T. porrifolius,* the SALSAFY of the kitchen garden, grass-like, and much grown for its delicious roots. The culture of this is described in our article on *SALSAFY,* which see.

TRAILING AZALEA (*Loiseleuria decumbens*).—See *LOISELEURIA.*

TRAINING CLIMBERS.—See *CLIMBING AND TRAILING PLANTS.*

TRAINING OF GARDENERS.

With gardening as with other professions, there is no royal road to success; those who would reach the summit must commence at the base and climb upwards. Gardening is essentially practical; by theory alone no one can hope to become a successful gardener. At the same time, without a knowledge of the principles upon which horticulture is based, the gardener is likely to make many errors, or to be in doubt how to proceed when meeting with a new difficulty. There are, of course, thousands of skilful gardeners who have never devoted time to acquiring anything but practical experience; but the day of empiricism is passing, and as time goes on it will be more than ever recognised that the best-equipped gardener is the one whose practice is fortified by knowledge, and who does not work by "rule of thumb." This has been recognised by the Royal Horticultural Society, which confers diplomas in horticulture, and, in conjunction with the University of London, grants degrees. Its examinations combine both theory and practice, and candidates are required to show that they have had a certain period of training as gardeners; while at the Society's school at Wisley the curriculum embraces various branches of garden work, together with instruction on the scientific side, given by experts. All this, of course, is for those who aim to fill high positions; those whose aspirations are lower may deem much of it unnecessary. There have been great gardeners who have had no scientific training, but they have been close students and observers, and have

generally given much time to solving the problems before them.

As a rule, the youth who desires to adopt the profession of a gardener obtains an engagement at a private establishment, where he serves an apprenticeship of three years or more. He may perhaps start as "garden boy," and if he is industrious and intelligent he soon passes through the elementary stages. At the end of the apprenticeship he becomes a journeyman, and may either continue in the same employment, or migrate to another establishment, where his experiences will be different, but all tending to make him a finished gardener. At this time, too, if he be wise, he will seek to acquaint himself with the "why and wherefore" of some of the horticultural principles on which gardening is founded. Attached to most gardens of any pretensions is a "bothy," where he will be lodged.

Whether as apprentice or "boy," the first duties will be of a lowly and humdrum character, such as washing and crocking pots, mixing composts, and making himself generally useful. His subsequent training will include various operations connected with the cultivation of the land, such as digging and trenching; draining and making watercourses; the differences in soils, and how to prepare them for the needs of different crops; the making of seed beds; thinning out and transplanting; and hoeing and weeding.

In the matter of propagation there is the sowing of seedlings, with the conditions requisite to successful germination; pricking out, and potting on or planting out; and various sorts of cuttings and how to deal with them; increasing by layers and division; and the selection of suitable stocks for budding and grafting. Pruning, training, cutting back, disbudding, tying, and staking of trees, bushes, and plants of all sorts will also engage attention.

Under glass there will be the culture of Vines, Peaches, and other fruit, and of the innumerable flowering and foliage plants.

In vegetables there will be the requirements of the various crops, and their rotation, with the best varieties for local conditions.

Other matters will include the forcing of vegetables, fruits, and flowers, the management of the greenhouse, giving attention to ventilation, temperature, and watering; the uses of manures, "natural" and artificial; the packing of produce for transit by road and rail; the artistic arrangement of flowers in the conservatory and winter garden, and for indoor decoration; the planning of beds and borders and the laying out of a garden; and the recognition of insect and fungoid pests, and taking measures to prevent and eradicate them.

The foregoing is an outline of some of the things which the modern gardener should endeavour to master, and it is not to be supposed that all can be acquired in the brief space of an apprenticeship; indeed, the earnest gardener is always learning. It will be seen that in many things scientific study will help to make the task easier, and save much uncertainty and profitless labour. Among the subjects that can be thus learned are the physiological structures of all parts of plants, from the seed stage upwards, so that the individual characteristics of each, and their requirements, are understood; the processes of fertilisation and the methods of hybridising and cross-breeding, also the improvement of strains and varieties; the chemical composition of soil, and of fertilisers and manures; the causes that set up disease, and also the remedy. Then there is the classification of flowers, fruits, and vegetables, which often gives a clue to their cultural requirements. These and many other related subjects, though belonging to the theoretical side of gardening, are yet closely connected with practice, and are well worth the gardener's learning systematically. There is so much to learn that a lifetime is not long enough to learn it all; but every item learned adds to the gardener's usefulness and value, and increases his pleasure in his work.—W. J. C.

TRAINING OF PLANTS.

There are two reasons why plants under cultivation have to be trained: (1) Because we wish them to cover a certain space and look neat instead of straggling; and (2) to guide the energy of a plant into channels which will cause it to bear flowers and fruit, instead of allowing it to waste this energy on useless leaf and wood growth. There is not the slightest doubt that *judicious* arrangement by thinning of, say, a

chrysanthemum, leads to the production of finer (though fewer) blooms. The subject of training plants is a large one, and is best considered in two sections: (1) Trees and Shrubs, and (2) Climbers.

Trees and Shrubs.—Fruit trees are *pruned* in autumn or winter, and *summer pinched* in July to induce the formation of fruit buds. If trained on walls or trellises due regard must be paid to the fact that branches must not be too close together, while they should cover all the available space evenly.

Of late years, flowering shrubs, such as the various varieties of Berberis, Philadelphus (MOCK ORANGE), Prunus, Syringa (LILAC), etc., have become popular. These are best thinned out in February or March; the work, however, must not be done too severely, and where flowers are borne only on the previous year's growth it is, of course, fatal to cut this away.

SHRUBS. — Such subjects as Aucubas and Euonymuses, as well as hollies and laurels, may also be trimmed into shape in spring. Box and yew are very suitable for the old-fashioned topiary work. They are trimmed in March with shears into the forms of cocks, dragons, etc., and form a fitting background to a herbaceous border.

Climbers.—It is with the climbing plants — or plants treated as climbers—that the true art of training is seen. If left to themselves, roses, wall-coverers such as ivy, Ampelopsis (VIRGINIAN CREEPER), Clematis, climbing vines (Vitis of sorts), greenhouse subjects such as Ipomoea, *Tropaeolum tuberosum*, Fortune's yellow rose, and the grape vine would become a mere tangle of growth. Hence they are usually trained to wires passed through eyeletted staples and strained by raidisseurs at the ends.

Materials for Training.—Bast is best for tying soft-wooded plants because it "gives" as growth increases. For harder-wooded plants, such as Roses and Escallonias, as well as climbers on walls, tarred string may be used. Shreds of old cloth 4 ins. long and 1½ ins. wide, used doubled, and held by special square wall nails, are preferable for brick walls. In no case must the stem be too tightly held. Even large growths may be amply secured by bast.

In training any plant the gardener should never forget that it is better to *lead* its activities in the desired direction rather than to attempt to drive or force it, which last often proves fatal. The final aim should be kept consistently in view and patiently awaited, whether it be the production of a perfect flower or of a well-shaped tree.—T. C. D.

TRAINING OF WOMEN STUDENTS.—See *WOMEN GARDENERS*.

TRANSPIRATION.—See *PLANT PHYSIOLOGY*. It is also referred to in *BOTANY FOR GARDENERS*, and *LEAVES OF PLANTS: THEIR FUNCTIONS*.

TRANSPLANTING.

The work of transplanting is an important detail in the life and growth of all horticultural subjects, embracing as it does a wide sphere, and upon the manner in which the work is carried out may depend the future success or failure of the subject in question.

The term transplanting covers a wide area embracing vegetables, flowers, plants with tap-roots as well as fruit trees, small fruit trees and shrubs, although the term is more commonly applied to seedlings.

Vegetables.—In the case of such crops as Cabbage, or any of the

Brassica tribe, these, we may say, entirely owe their success to the initial detail of transplanting when the seedlings are large enough to handle. Many unsatisfactory crops can be traced to the wrong method of transplanting, or indeed the want of method. Very often the work is delayed too long; thus the plants become drawn up, weak, and attenuated owing to a want of space for free development. The plants when pulled up, as they are all too often, receive a check straightaway. Many of their fibrous roots are injured at the time, and the plants have to set to and recuperate themselves owing to the loss of wherewithal to establish themselves. Overcrowding in the seed-bed often results in what are known as "leggy" plants, which never become as sturdy in their subsequent growth as those that were transplanted earlier.

The common method of drawing Brassica or indeed any other seedlings from the seed-bed is highly unsatisfactory, even when the plants are as strong as one might desire. Instead of pulling up such subjects as Lettuce or Onions, for example, especially in dry weather, and thereby injuring their roots, the correct method of taking them out of the seed-bed is first to water the soil if the weather is dry, thus ensuring the retention of fibrous roots, and instead of pulling up roughly, to lift them up with a hand-fork, and thus release the roots, which then leave the soil intact. The common method of planting is with a dibber, but for the pros and cons of this way of working the reader should refer to our notes on *Dibbers: Their Use and Abuse*. A hand-fork and trowel are much the best tools for lifting and transplanting these small seedlings; by making a hole with the last, the roots are more evenly spread out, and the soil goes amongst the fibrous roots in such a manner that hardly any check takes place, the result being immediate new growth of a sturdy character.

Flowers. — The same remark applies to all seedling flowers such as Asters, Stocks, and such like; a little extra trouble and time spent makes all the difference between success and failure.

Plants with Tap-Roots.—In transplanting such subjects as Beet, Parsnips, or any plant with a tap-root which should remain intact, the rough pulling up of the plants is almost certain to lead to failure, since the loss of tap-root means a shorter root when the time comes for the harvesting of these subjects. Especially, then, it is necessary to lift these seedlings with a fork, and to prepare the new site with care for their future growth.

Shrubs or Trees.—In transplanting these, the main point is to spread the roots out carefully so that they are uniformly covered with soil from the base to the surface. The roots should be evenly disposed, the bulk of them being kept as near the surface as possible, in order that they may derive benefit from the warmth of the sun as well as from surface dressing of fertilisers, etc.

Mistakes to Avoid.—One of the greatest mistakes in fruit-tree and rose transplanting is that of allowing the roots to become dry while waiting to plant. The small fibrous portions are often so injured by exposure that they are useless, the tree having to form more before they can be of any use as sustainers of growth in supplying the liquid plant-food by which all plant-life exists.

E. M.

[It may be well to add that the mistake is to let any roots of plants, whatever the plants may be, become dry prior to setting them in new quarters, as such always results in a

more or less severe check to growth. Usually it is quite possible to avoid them getting dry by taking a little trouble. As a rule trees and shrubs should never be pruned when being transplanted, though when necessary they may be root pruned. Another point to note is that manure should not be put in direct contact with the roots of trees and shrubs, or indeed anything during transplanting, nor should artificial fertilisers be used until the subjects have had time to become re-established.—EDITOR.]

TRANSPORTED DEPOSITS.— See under SUPERFICIAL DEPOSITS in *GARDEN GEOLOGY*.

TRAPS.

Ready-made traps can be purchased so cheaply for birds, mice, moles, rats, slugs, and snails that it is unnecessary to make them for oneself. Effective earwig traps can either be made by filling pots with hay, and putting them on the tops of dahlia poles, etc., or by cutting bean stalks into lengths and slipping them among the foliage of the plants. Cockroach and wasp traps are best made of wide-necked bottles filled partly with treacle, syrup, or some strong smelling viscid liquid. The former are put on the ground for the creatures to crawl into, while the latter are hung up in trees for the wasps to fly into. Both should be emptied at frequent intervals.

TREE STUMPS : CLOTHING.

Tree stumps are ugly, and serve to mar the garden rather than to beautify it in most cases, but it is a great pity to destroy them if their situation is such that plants may be grown over them. Many rock plants, such as Alyssum, Arabis, Aubrietia, and Cerastium will revel if allowed to romp over them, and will beautify the garden if allowed to do so. A fair proportion of the plants described in our article on *CLIMBING AND TRAILING PLANTS* may be planted in soil above such stumps to ramble over them with great effect; indeed there is no end to the possibilities of tree stumps in the hands of intelligent gardeners.

TREE STUMPS : DESTROYING.

It is sometimes necessary to destroy tree stumps if these are

situated in positions where it is impossible to beautify them by clothing them in the ways mentioned in the preceding article. Various methods have been suggested, such as drilling holes and watering with saltpetre solution, and a week later lighting a small fire on the top, but this involves a good deal of unnecessary waste of what might be utilised as valuable fuel. It is a far better plan to drive iron wedges into the stumps with a sledge-hammer, and so split each stump first of all into two halves. Then by repeating the process across the length of the two halves the stumps are divided into four. Usually such pieces can be lifted without much difficulty, though, of course, the roots holding the stump into the ground must first be cut through. The split pieces can either be further cut up before use, or put just as they are into the greenhouse furnace, when they will keep the fire in for a long period, as the wood will be damp.

TREE WASP.— See under WASPS in *INSECT PESTS*.

TREE WOUNDS.

Fruit Trees especially are very liable to wounds of various kinds, due sometimes to carelessness in pruning, sometimes to the wind moving their stakes about and so chafing away the bark, while at other times their cause is difficult to account for. These wounds if neglected may have serious consequences, and mean the premature death of the tree owing to bleeding, or to the letting in of diseases. The best thing to do is to paint them over as soon as possible either with Stockholm Tar or Burgundy Pitch. Special Styptics are on the market, the use of which gives good results, though as a rule these are somewhat expensive.

TREES.

In the present edition we are not attempting general descriptions of Garden Trees, or an exhaustive list of these, but we give below a selection of easily-grown, desirable species, with a few of the best varieties. All are hardy, unless otherwise indicated, in average districts of the United Kingdom. The letters in parentheses immediately after the botanical name indicate the nature of the tree, whether evergreen or otherwise, *E.* standing for hardy evergreen; *D.* for hardy deciduous; *H.H.E.* for half-hardy evergreen; *H.H.D.* for half-hardy deciduous; *T.E.* for tender evergreen; and *T.D.* for tender deciduous. *C.* after the generic title shows that the tree belongs to the Conifers. On account of the confused nature and large number of synonyms it has been thought best to omit most of these. The heights given are approximately those attained by the trees in cultivation, but these vary greatly under different conditions, and in their native habitats vary more greatly still. Some of the trees have not been sufficiently long in cultivation in this country to show the stature they will eventually attain, hence the omission of a certain number of heights. In future editions it is hoped that further information on this point will be available.—EDITOR.

TREES AND CLIMBERS FOR GARDENS.—See *Town and City Gardening.*

TREES, CUTTING OF: Law as to.—See *Gardening Law.*

TREES: Planting.—See *Planting.*

TREES: RAISING FROM SEED.

[So much re-afforestation is now necessary on account of the enormous drain on our wood supplies that we feel a brief sketch of this subject will be useful to those who may want to help on the national work. For fuller details larger encyclopædias or works on forestry must be consulted.—Editor.]

Making the Seed-Beds.—Before starting to make the seed-beds, we must first know how many plants will be required to plant a given area and to replace deaths during the first few years. Suppose an area of 20 acres is to be planted with trees 4 ft. apart, 2722 trees will be needed per acre. The mortality of plants from various causes may be reckoned at 10 per cent. Thus $2722 + 272 = 2994$, or say 3000, which multiplied by 20 gives 60,000 as the number required.

The next thing is to find out how many seeds there are in 1 lb. of the species to be sown.

Let us take Scots Pine as an instance. There are approximately 75,000 seeds in 1 lb. If every grain of this seed germinated and came to maturity, there would be more than enough to plant 20 acres; but the average germinative capacity of Scots Pine is only about 65 per cent., roughly 49,000 plants from 1 lb. But, although there may be 49,000 seedlings at first, a large number of these will never, for various reasons, grow to strong plants, and must consequently be left out of the reckoning, since it is not safe to rely on getting more than 15,000 strong seedlings from 1 lb. of Scots Pine

seed. Thus we find that it will take at least 4 lb. of seed to produce 60,000 strong seedlings.

If the seeds are to be sown in lines along the bed as described later, the number of plants that can be grown per square yard is about 2500. (About 25 per cent. more seed can be sown per square yard on broadcast beds.) This, on a bed 3½ ft. wide with lines 6 ins. apart, seven to a bed, works out at 360 plants per lineal yard of drill, or ten plants per lineal inch, and about two per square inch of ground. Generous spacing will, however, always produce a higher percentage of good plants.

As 1 yd. of the bed will grow 2500 plants, a bed 24 yds. long will be needed for 60,000. The ground upon which the beds are to be made should have been root-cropped, preferably with potatoes, the previous year, and during the winter should have been dug over roughly once or twice to allow frost and sun to sweeten the soil. A day or so before making the beds, it should be dug over again finely, all lumps broken and all big stones removed.

In making the beds, two garden lines should be stretched parallel, 3½ ft. apart, and some of the finest soil at the sides of the proposed bed should be added to raise it above the adjoining soil. The bed should then be raked very finely, until it is almost like coarse meal, and then levelled off. It must then be allowed to consolidate slightly before the seed is sown.

Methods of Sowing.—There are three principal methods of sowing, viz. broadcast sowing, line sowing, and dibbling. The third is only used when sowing such seeds as acorns, chestnuts, etc., and although seldom used now on nursery beds, is sometimes practised when sowing seeds direct into plantations.

When broadcast sowing, a "cuffing" board, shaped similarly to a rake, but with a board in place of the toothed head, is used to push back the top soil of the bed to either side from the centre, leaving a smooth surface upon which the seed is scattered evenly by hand or from a perforated tin. The cuffing board is then used to pull back the soil. This is done by placing the board behind the heap of soil and giving a sharp pull. An expert can, of course, spread the soil very evenly, but amateurs require a lot of practice, as the seeds must be buried at an even depth. If a board is not available the soil may be sifted on. The depth varies with the species, but a good rule is to bury it as deep as the length of the seed, allowing for a slight subsidence of the soil, especially with the larger seeds.

In line sowing, the lines may be made either along or across the beds, but when the latter method is employed, it is easier to hoe between them without treading on the beds, which must be avoided. When they run lengthwise, a line must be stretched every 6 ins., and a drill made with the corner of a hoe or the back of a light rake.

Another method of making the drills is to use a light wooden roller, which is encircled by bands of wood or iron spaced to requirements. These press into the soil as the roller is pulled along the bed, leaving small trenches for the reception of the seed. The roller can also be used for making lines across the bed, but with the bands running across the roller. The best method, however, of making the lines across the bed is by means of the Bavarian Drill Board.[1]

[1] For description of this tool and the sowing lath, a work on Forestry should be consulted.—EDITOR.

The best way to sow the seed is by means of the sowing horn, or the sowing lath, several types of which are easily made. The required quantity of seed is placed in the lath, which is turned over above each drill and the lid withdrawn, allowing the seed to fall into place.

After sowing is finished, the drills can be filled by drawing the back of a light rake over the beds, or if the drills are not sufficiently deep for this, some soil should be sifted on to the bed through a ¼-inch sieve.

Protection of Beds.—To protect the bed against mice, birds, etc., boards about 8 ins. wide should be fixed on edge along the sides of the bed, with 3 ins. of the width below ground, and covered with small mesh wire-netting fixed on frames about 6 ft. long, that can be lifted off when the bed is to be weeded, for protection against frost. These frames are sometimes covered with plasterers' laths placed about 1 in. apart. These not only help to keep the frost off, but also prevent too rapid evaporation of the frost by a hot sun.

Weeding.—During the whole time from sowing the seed to the lifting of the plants, weeds must be completely kept down, as once they get big it is difficult to remove them without lifting many seedlings as well. When the plants are in lines it is possible to use a hoe, which not only keeps down weeds but prevents excessive evaporation of moisture from the soil. In fact, hoeing is often better than watering and should even be done in addition to watering. The latter tends to cake the top soil, and evaporation is more rapid from caked surfaces. Mulching with leaf-mould or short grass cuttings is also useful to prevent this.

After Treatment.—When the planting area is exceedingly clean, very small plants can be used, and some species are fit to plant out at the end of the second year. If larger plants are needed, the seedlings must be lined out in the nursery for a year or two.

In lifting the seedlings, a fork or graip should be used, and the plants lifted clear of the bed, when the strongest ones can be selected and pulled out without damaging their roots.

With hard-woods, the tap roots may need pruning. This must be done with a sharp knife, but they must not be shortened too much, otherwise there will not be enough roots to keep the plants alive. After being lifted, the plants should for convenience sake be counted and tied in bundles of one to five hundred according to size, and are then ready to be carried, either to the nursery lines or to the planting area.—W. H. W.

TREFOIL.—See *TRIFOLIUM*.

TRELLIS WORK.

The mere suggestion of trellis work in a garden opens up many possibilities, for we realise how very attractive the growth of plants and flowers can be made by such supports. Trellis, of course, includes ornamental fixtures of metal and wood in either form assisting the proper training of roses and similar plants, and enabling gardeners to keep trailing subjects in order, and to adapt their use to quite small gardens.

Trellis is very useful when additional boundary height is needed; it adds to the appearance of walls and other buildings by enabling the gardener to hide them by foliage plants and creepers.

Metal arches, roseries, and porches are sold ready made. They are varied in design, and suitable for almost any style of architecture. Continuous covered-way espaliers of metal are not necessarily of metal trellis, but they may be used in conjunction with decorative schemes. Another type of close mesh trellis, rustic or made of wood laths, may be used as the division of the kitchen from the floral garden in the suburban villa plot where the two elements, profit and pleasure, are combined. Trellis porches, some covered with zinc, add to the appearance of the house and especially of the door giving entrance to the garden.

Wood trellis appeals to the professional and the amateur gardener alike, for it is easily adaptable, and can be worked to any space available. Cheap arches of trellis are made in stock sizes, and can be bought in widths varying from 4–6 ft., the depth being usually 1 ft., and the height generally about 8 ft. Trellis, extending when opened out, is made in 12-ft. lengths, the usual mesh being 3 ins.; the stock heights available are, when fixed, 2 ft., and every foot up to 6 ft. For filling up odd places bundles of laths 1 in. by 4 ins., in lengths of 6 ft., are sold. Top and bottom rails, and inside rails, are also sold ready made.

Expanding trellis is sold plain, and it can be painted when fixed complete; but it is better when made of laths which have been first painted, and then the whole painted again when fixed. Another kind is made first and then creosoted. This resists decay very well, even when resting upon damp soil.

Gardeners who are handy with tools can greatly enhance the beauty of a flower garden by introducing trellis divisions and arcades; a succession of arches and trellis covered with roses makes a great difference in a garden and does not occupy much room; indeed, there is no end to the variety of combinations which can be made with lengths of trellis and arches and other ornamental structures. The handy workman can build up in this way summer-houses, and cover over passages and paths, shutting out back premises and unsightly corners.

Another very popular form of trellis is made of the thinnings of plantations, the prunings of larger trees, and rustic timber, sold by dealers for the purpose in suitable lengths. When made up tastefully it looks very well and does not require painting.

In fixing trellis posts it is best to tar the portions which are placed in the ground, and add to their stability by surrounding them with cement or concrete, or drive in short posts to which they should be fixed to help them to resist wind pressure, or they may snap at some weak point.

Miniature trellis for pot plants and for use in conservatories encourages the growth of such plants, and helps to spread the stems and trailing branches so that the full benefit of floral display can be had.

Wire trellis is not much used, as plants do not take to it readily unless it is thoroughly and frequently painted.

For plants which may be used on trellis work, reference should be made to our article on *Climbing and Trailing Plants*.—F. W. B.

TRENCHING.—See *Soil Cultivation*.

TRESPASS OF NEIGHBOURS' FOWLS, Etc.: Law as to.—See *Gardening Law*.

TRIANGULAR BEDS: Area of.—See Areas of Beds and Borders in *Arithmetic and Gardening*.

TRICHERA.—Now included in the genus Scabiosa. See *Scabious*.

TRICHOLAENA.—Now included in the genus *Panicum*.

TRICHOMANES.—For the best species see *Ferns and Fern Gardening*.

TRICHONEMA.—Now included in the genus *Romulea*.

TRICHOPILIA.—See *Orchids*.

TRICUSPIDARIA.—For the best species see *Shrubs*.

TRICYRTIS.—See *Toad Lily*.

TRIENTALIS (Nat. Ord. Primulaceæ).—Only two species of this genus are usually grown, and both are suitable for the rock garden, rock border, or as edgings to herbaceous borders if given a shady and moist site. *T. americana*, known as the Star-flower, blooms about July, while *T. europaea* (Syn. *T. alsinaeflora*), the well-known Chickweed Winter-green, blooms in May. Both bear white flowers, both average 6 ins. in height, and both require nothing more than the usual culture given to small rock or border plants. The best means of propagation is a matter of opinion: some say seeds sown in summer, and others say root division in early March.

TRIFOLIUM (Trefoil and Clover. Nat. Ord. Leguminosæ).—This is a very large genus of hardy annuals and perennials, thriving in most light soils, and of the easiest culture. Very few are of any value in the garden, though sometimes grown for green manuring. The species named below, with their English names, are the best known: *T. agrarium*, the Hop Clover; *T. arvense*, the Hare's-foot Trefoil; *T. dubium*, the Shamrock of Irish fame; *T. fragiferum*, the Strawberry Clover; *T. hybridum*, the Alsike Clover; *T. incarnatum*, the Crimson Clover; *T. Lupinaster*, the Bastard Lupine; *T. maritimum*, the Teasel-headed Clover; *T. medium*, the Meadow Clover; *T. pratense*, the Common Clover; *T. procumbens*, the Hop Trefoil; *T. repens*, the Dutch Clover; and *T. stellatum*, the Star Trefoil.

Border Species.—None of the above are of much value for herbaceous or perennial borders, as they are of too common a habit. Thus it may be well to name one here of real use, and distinctly uncommon. This, *Trifolium pannonicum*, bears yellowish flowers from June onwards, and averages about 12 ins. high.

New Species.

Trifolium uniflorum.—This bears purple and white flowers singly, not in heads as is usual. It is a good plant for the rock garden.

TRIGLOCHIN.—See *Arrow-Grass*.

TRIGONELLA (Fenugreek. Nat. Ord. Leguminosæ).—This is a large and unimportant genus mostly of hardy annuals, hardly worth cultivating. The medicinal use of *T. Foenum-graecum*, the Common Fenugreek, is fully described in some of the older Herbals, but it has now fallen into disrepute. The plant bears white flowers in July, and averages about 2 ft. in height.

TRILLIUM (Three-leaved Nightshade, Trinity Flower, or Wood-Lily. Nat. Ord. Liliaceæ).—This is a useful genus of hardy tuberous-rooted perennials suitable for border or rock garden culture. They require plenty of peat in the soil, which should nevertheless be light, and though they prefer a little shade, a sunny

position will suit them. Propagation by seeds in the summer, and root division in the autumn or spring (at which last period they are best planted), is not a matter of very great difficulty, though there are some plants, it is true, which are easier to increase than these. Paxton says that the roots of all species are violently emetic.

What to Grow.—We recommend the following species—the dwarfer ones for rock garden purposes :—

Trillium californicum.—Syn. *T. ovatum*, which see.

T. cernuum.—This is a white May blooming sort about 1½ ft. high.

T. erectum (Syn. *T. foetidum*).—This, popularly known as BIRTHROOT, is a dark purple sort flowering in May, and growing about 1 ft. high.

T. erythrocarpum (Syn. *T. pictum*).—Some authorities consider this species, popularly known as the PAINTED WOOD-LILY, which bears white and red flowers, to be synonymous with *T. grandiflorum*. Its flowers are borne with some profusion from April to June, on plants 6–9 ins. high.

T. foetidum.—Syn. *T. erectum*, which see above.

T. grandiflorum (WAKE ROBIN).—This bears white or rosy-pink flowers from June to July, and averages 6 ins. in height.

T. ovatum (Syn. *T. californicum*).—This useful sort bears light purple blooms from May onwards, and grows about 6 ins. high.

T. pictum.—Syn. *T. erythrocarpum*, which see.

T. sessile californicum.—This is a favourite species bearing white flowers in May, and growing about 6 ins. high.

TRINIA (HONEYWORT. Nat. Ord. Umbelliferæ).—This is a genus of hardy biennial plants sometimes offered as choice subjects to unwary amateurs. All the species are worthless from a floral point of view, so the space is best planted with other subjects.

TRINITY FLOWER.—See *TRILLIUM*.

TRIODIA (Nat. Ord. Gramineæ). This is a genus of hardy perennial grasses only suitable for the wild garden. *T. cuprea* and *T. decumbens* are the two best species—the last is the HEATH GRASS, and is the least valuable of the two.

TRIPOLIUM.—Now included in the genus *ASTER*.

TRIPSACUM.—See *BUFFALO GRASS*.

TRITELEIA.—Now included in the genus *BRODIAEA*.

TRITICUM (WHEAT. Nat. Ord. Gramineæ).—Few gardeners realise that this genus contains the COMMON WHEAT (botanically known as *T. vulgare*), from which flour for bread is made. Most of the species are now classed in the genus *AGROPYRON*, on which a separate note appears, but the present genus includes that previously known as *Ægilops*. Both genera are very similar and contain mostly weed plants of no value. *T. monococcum* (ST. PETER'S CORN), and *T. polonicum*, the POLISH WHEAT, are grown to a very limited extent in gardens.

TRITOMA.—A synomyn for *KNIPHOFIA*, which see.

TRITONIA.—See *MONTBRETIA*.

TROLLIUS (GLOBE FLOWER. Nat. Ord. Ranunculaceæ).—The four species of this hardy perennial which are described in our article on *WATER GARDEN : PLANTS FOR THE*, are very suitable for the perennial border if a damp situation is chosen. They are easily grown, very showy, and in every way highly desirable.

NEW VARIETY.

Trollius King Cup.—This is a late flowering sort bearing golden-yellow and orange flowers on erect branching stems.

TROPAEOLUM.—See *CLIMBING AND TRAILING PLANTS* and *NASTURTIUM.*

TROPICAL PLANTS.

The flora of the tropics is represented by hundreds of genera and species belonging to many Natural Orders, which, living under the varied conditions of the tropical world, present varying degrees of beauty or of usefulness, while quite a large number are of purely botanical interest only. Of the many beautiful tropical plants, a large number are included in the ordinary stove collections, while those whose usefulness renders them valuable to man are termed Economic or Medicinal plants, and are seldom met with outside our botanical gardens.

It will be readily understood that plants living in the tropics do so under widely different conditions in various regions, and it is necessary to provide conditions which shall approximate those obtaining in the natural regions from which the plants have been obtained. Generally speaking, this is a high temperature and abundant moisture during the growing season, with cooler and drier treatment during a period of rest.

It will be obvious that in a Gardening Dictionary planned for general use a fuller description of such tender plants would be out of place.

TROWELS.—See *GARDEN TOOLS.*

TRUE LAVENDER (*Lavandula vera*). See under LAVENDER in *POTHERBS.* See also *LAVANDULA.*

TRUE PITCH PINE (*Pinus palustris*). See *TREES.*

TRUFFLES.

These cannot be cultivated, generally speaking, in this country. They are, however, often found wild in Oak or Beech woodlands attached to gardens, and can be dug as required.

TRUMPET DAFFODILS.—See *DAFFODILS.*

TRUMPET FLOWER (*Tecoma radicans*).—See *CLIMBING AND TRAILING PLANTS.*

TRUMPET LILY (*Lilium longiflorum*). See *LILIES.*

TRYPSIN.—A ferment necessary for successful germination. See *GERMINATION OF SEEDS.*

TSUGA.—For the best species see *TREES.*

TUB GARDENING.

Very good gardening is possible in vases, tubs, boxes, or extra large pots. Such expedients are especially valuable where the garden is small, or limited to courtyards and such enclosures. Familiar examples of this gardening are seen in our window-boxes and the pot-grown plants of the greenhouse. In a number of the big gardens too, plants in tubs play some part, usually that of giving yet greater effect to some portion of the flower garden—perchance the terrace, or by a pathside, or grouped around some approach. But the great advantage of this branch of horticulture lies in the possibilities it provides, in allowing persons with restricted garden space to cultivate and enjoy the possession of plants otherwise impossible to have; also as being a means whereby some half-hardy plants can be used in the open air for a few months, and which, being so grown, can be easily moved to a frost-proof shelter when such time arrives. There would seem to be no need for putting plants in any receptacle if they will live out in the open ground safely through

an average winter—but oftentimes they are so placed to satisfy some particular design or wish.

Suitable Receptacles.—Tubs and boxes may be made any size and painted any colour, but dark green is most likely to be in harmony with gardening surroundings and to give the most pleasing effect. Several holes must be bored in the bottom of each box or tub used to ensure proper drainage and aeration. If special boxes have to be made, it will be cheapest in the long-run to procure the best material; but excellent tubs can be had by sawing paraffin casks in half. Small margarine tubs also answer the purpose well. The most durable receptacles are, of course, of stone. In pot ware, beside the usual large pots common in gardens, there are artistic patterns obtainable, with large saucers in which to stand them. Large fancy jars, too, are to be had, and look well when filled with appropriate plants. To prevent a too rapid evaporation, pots and jars should be glazed. Window-boxes are sometimes seen done with glazed tiles.

Concerning Suitable Plants.—Although so many plants are amenable to culture in tubs and vases, yet some show better results than others. In making a choice of plants, we must consider their future development; otherwise tall or large, bushy specimens may be put in a vessel better adapted for small or dwarf-growing subjects. Free-growing plants want adequate room for soil and moisture, but these essentials can be over-subscribed, thus causing an unhealthy state of the soil and premature decay of roots. On the other hand a cramped plant or shrub generally wears an impoverished look—unless lavishly supplied with stimulants. A little practice soon enables one to choose the happy medium.

List of Plants.—A few old favourites answering well to this mode of treatment are: Agapanthus, Aloe, Aloysia, Aralia, Bay (sweet), Chamaerops, Chrysanthemum (annual and perennial sorts), Dracæna, Ferns (tree), Fuchsia, Funkia, Geraniums (Zonal, Oak-leaved and Ivy), Grevillea, Hydrangea, Kalmia, Laurustinus, Lilium, Myrtle, Oleander, Rhododendrons (dwarf), and Schizostylis.—C. T.

TUBEROSE (*Polianthes tuberosa*. Nat. Ord. Amaryllidaceæ).—This is a sweet-scented bulbous plant from Mexico, with thick fleshy white flowers borne on a long slender spike at regular intervals. The individual flowers are used for buttonholes and wreath-making after being wired. When grown in pots, they may be used for conservatory decoration. They are too strong scented for the majority of people in living rooms.

Culture.—There are two strains, the African and the American. The former may be potted in October, November, and December for flowering the following autumn, while the latter may be potted in February, March, and April for flowering the following winter. One bulb may be put in a 5-inch pot, or three in a 6-inch. A suitable compost for potting may be made up of fibrous loam, old decayed manure, leaf-mould, and silver sand. The bulbs after being potted should be plunged in a cool greenhouse or cold frame and no water given until growth commences. When this occurs and the young spike is 2 ins. long, the pots should be removed to a light airy position in a greenhouse, and frequent stimulants given. The spikes grow from 2 ft. to 3 ft. high, and after flowering the bulbs are of no further use.

If the more forward of the bulbs

are planted out in the open in early June in a warm and sunny position and given plenty of water, they will bloom in August or September in an ordinary season. Used in this way their heavy scent is very pleasant to get in whiffs as one passes the places where they are planted out. *Excelsior Pearl* is a good and favourite variety.

TULIP DISEASES and TULIP DIVISIONS.—See *TULIPS.*

TULIP POPPY (*Papaver glaucum*).—See *POPPIES: ANNUAL SPECIES.*

TULIP SPECIES.

There are a very large number of species, but their general cultivation cannot be recommended. The best species are *T. biflora, T. clusiana, T. cuspidata, T. Didieri, T. flava, T. fulgens, T. gesneriana, T. maculata, T. praecox, T. pulchella, T. triphylla,* and *T. violacea. T. sylvestris* is the WILD TULIP, only suitable for the wild garden. There is a good colour range in the above species, yellow, red, purple, and scarlet being some of the chief colours. The blooming period is mostly April, though some continue even until July, while the height of most rarely exceeds 1 ft. Detailed descriptions of all the above and hosts of others will be found in larger works.

TULIP TREE.—The genus LIRIODENDRON. See *TREES.*

TULIPS: History.—Tulip history begins in the year 1554 when the Ambassador of the Emperor Ferdinand saw Tulips growing in a garden on his way to Constantinople. Previous to the above date all is conjecture; but from the behaviour of the seedlings obtained from the first bulbs brought to middle and western Europe it may be presumed that Tulips had for a long time been cultivated in Turkey. The flower came into the limelight in the years 1634–1637 when that extraordinary speculation known as the Tulipomania took place. Many tales are connected with this period, founded upon the undoubted facts that many of the more famous varieties like *Semper Augustus* were sold for far more than their weight in gold. Ever since it has been a favourite garden and florists' flower. In England it reached the zenith of its popularity from about 1840 to 1860. Then for twenty-five years it was somewhat under a cloud. The introduction of the fine tall race known as Darwin Tulips in 1889 has once more reinstated it in favour.

Books on Tulips.—For those who make a speciality of Tulips the following works will be useful: (1) *Tulips,* by the writer of this article, in the "Present Day Gardening Series"; and (2) the *Report of the Tulip Nomenclature Committee* issued by the Royal Horticultural Society in 1917.

Tulips: Special Feature. — A characteristic of the Tulip which is shared by few other flowers is its habits of "breaking." Except some yellow and red varieties, every garden Tulip begins life as a "self." Sooner or later the self-colour changes and the flower becomes striped or blotched. That is technically known as "breaking." No one can say when this change

will occur. It may be in two or three years, or it may be not for twenty or thirty.

Technical Tulip Terms. — The tulip being a very old florists' flower many technical terms have grown up in connection with it. Some of the more common ones are :—

BREEDER or MOTHER TULIP, where the flower is all one colour.

BROKEN or RECTIFIED, where the flower has become striped.

FEATHERED, when in a broken flower the colour is confined to the edges of the petals.

FLAMED, when in a broken flower the colour is spread over the petals.

The BASE is the bottom part of the perianth segments or petals.

A ROSE is a tulip with a white ground and white base, and some shade of red markings.

A BYBLOEMEN has some shade of purple markings on a white ground. It has a white base.[1]

A BIZARRE is a flower with a yellow base and a yellow ground colour.

DROPPERS are small new bulbs which are formed at some distance below the old bulb. Two-year-old seedlings and young offsets almost always produce them.

PARROTS are varieties with laciniated petals.

Outdoor Tulip Culture. — Tulips do not thrive in grass. After a few seasons they practically refuse to bloom. Any good garden soil is suitable, but the best results are obtained in land just on the stiff side. Lime is valuable. Cold draughty places should be avoided. Bulbs should be planted from 4–5 ins. deep; the lighter the soil the deeper the bulb. It is better to lift Tulips every year, but this is not absolutely necessary. Lifting should take place between 27th June and 7th July. The exact time is when the skin of the new bulb is just turning brown. Store in a cool airy shed or room away from the sun. Plant the smaller bulbs (offsets) in nursery beds in September, and the large bulbs in the first fortnight of November.

Indoor Tulip Culture. — Pot all varieties in September or early October in good light, rich soil. Darkened cold frames are to be preferred for the newly potted bulbs instead of plunging in the usual way. The young growth is tender and liable to be eaten by slugs and green fly, and to be effected when bruised with some kind of fungus. Darwin Tulips have been found to do well when brought on in gentle heat. The early forcing of Darwins should only be attempted by experienced cultivators.

Propagation.—The seed pods as they ripen are very subject to fungoid attacks. It is best to grow all plants for seed under glass as cool as possible. Seed should be sown in early autumn in pans or boxes, and these should be stood in a cold airy frame. Seedlings may remain in boxes for two years, when the small bulbs may be planted out in well-prepared beds of good *light* soil. Seed may be sown in rows in the open, but as a rule it is not advisable to do so. Propagation may also be effected by taking off all small bulbs from the large bulbs before planting, putting the biggest of these in beds by themselves in September and throwing away the very small bits.

Tulip Divisions.—For a detailed explanation the R.H.S. Tulip book should be consulted. The main divisions are (1) *Earlies*; (2) *May*

[1] Pure white or yellow bases are only to be found in English Florists' Tulips. In all other types the base is usually more or less coloured or stained.

flowering, sub-divided into Darwin and Cottage; (3) *Species* and (4) *Florists'*. These last are the "show" varieties, and as their cultivation is a very technical matter, specialists should always be consulted.

Varieties.—Selections from the Rembrandt sections are omitted, as they are not so much grown in average English gardens as the "Earlies" and "May flowering" varieties.

(*a*) *Single Earlies* for pots or bedding.—Artis, Brunhilde, Couleur Cardinal, Cottage Maid, De Wet, Jenny, Keizerskroon, Lady Boreel, Prince of Austria, Rose luisante, Vermillon Brillant, Van der Neer.

(*b*) *Cottage* for out of doors.—Boadicea, Ellen Wilmott, Gesneriana major, Goudvink, Inglescombe Pink, John Ruskin, La Merveille, Louis XIV., Moonlight, Mrs Moon, Mrs W. O. Wolseley, Orange King, Picotee, Rose Beauty.

(*c*) *Darwin's* for out of doors and for cool treatment in pots.—City of Haarlem, Clara Butt, Edmee Euterpe, Farncombe Sanders, Flambeau, Frans Hals, Faust, Margaret, Mauve Clair, Professor Francis Darwin, Pride of Haarlem, William Goldring, Valentin.

(*d*) *Early Doubles* for pots.—Couronne d'Or (orange and yellow); Couronne des Roses (rose); El Toreador (orange); Murillo (blush); Safrano (primrose); Schoonoord (white); Vuurbaak (scarlet).

(*e*) *Late Doubles*.— Blue Flag, Yellow Rose.

(*f*) *Good Florists' Varieties*.—Annie McGregor, Dr Hardy, Mabel, Samuel Barlow, Sir Joseph Paxton, Talisman.

(*g*) *Good Parrot Varieties*.—Amiral de Constantinople, Luteo major, Cramoisi Brillant.

(*h*) *Reliable Species* for out of doors.—Batalini, Dasystemon, gallatica, Kaufmanniana, Marjoletti, Mauriana, persica, praestans, sprengeri, sylvestris.

DISEASES.

Fire Fungus.—A disfiguration of the flowers and foliage is frequently caused by a fungus called *Botrytis parasitica*. To avoid attacks, change of ground and annual lifting are advised. Cold draughty positions should be avoided. When the disfigurement is first noticed, excising all affected parts of the leaves with a sharp knife often prevents it spreading.

J. J. & E. T. E.

New Varieties.

The following are some of the best:—

Asturias.—A Darwin with purple flowers margined silvery-white.

Bloodstone.—A deep crimson Cottage Tulip with a violet base.

Comedy.—A Darwin with pink flowers blotched purple, and a white base.

Empire.—A bright yellow Cottage Tulip with a dark base.

Inglescombe Mauve.—A hybrid with silvery-mauve flowers, and a violet base.

Inglescombe White.—A pure white Cottage Tulip.

Lady Love.—A yellow Cottage and Darwin Tulip pale at the tip.

Marconi.—A Darwin with purple flowers, and a white base.

Samson.—An orange-scarlet early single Tulip.

Satin Gown.—A satiny-rose Cottage Tulip with a yellow base.

Zorilla.—A Cottage and Darwin Tulip with flowers red outside and orange-scarlet inside.—W. J. C.

TUNBRIDGE FILMY FERN (*Hymenophyllum tunbridgense*).—See *Ferns and Fern Gardening*.

TUNICA (Nat. Ord. Caryophyllaceæ).—This is a genus of dwarf-growing hardy plants allied to Dianthus, mostly hardy herbaceous perennials, but containing two annuals of insufficient importance to be described here. The species we describe are suitable for use as edgings, and for forming of patches in mixed, rock, or perennial borders, and are useful rock plants. They need no special culture save a light sandy soil, and may be propagated by division of the roots, and planted successfully in mid-March. We recommend the following:—

Tunica illyrica.—This bears red flowers in July, and grows 6–9 ins. high.

T. rhodopea.—This bears pretty rose flowers in July, and averages 4–6 ins. high.

T. Saxifraga.—This is deservedly the most popular species of all with its charming pink flowers in July, on plants 6 ins. high. Various forms of it are offered by the trade, including a single and double white.

TUPELO (*Nyssa sylvatica*). — See *TREES*.

TURBAN RANUNCULUS.—See under TYPES AND VARIETIES in *RANUNCULUS*.

TURBITH (*Euphorbia Esula*).—See *EUPHORBIA*.

TURF.

When gardeners speak of turf they mean either of two materials. They may mean fresh, green, growing turf cut from the meadow, or they may mean half-rotted turf which is nearly but not quite far enough gone to be called loam. In this work we say definitely which kind of turf we mean, for it is confusing to gardeners, especially if they are young and are learners, not to know what is meant.

Fresh green turf is useful if it is chopped up for remaking of vine borders. But it must be covered over with soil. It can also be used for putting into the bottom of pots especially for bulbs, where little drainage is required.

Its chief use, however, is found for loam-making. For this purpose it is cut thin or thick to suit the fancy of the gardener or the circumstances of the case, and stacked, grass-side downwards, in a sloping heap for at least a year. The sods should be about 1 ft. square, and the heap should slope similarly to a haystack, the sloping sides being covered, as a roof is with slates, with large sods laid on afterwards when the heap has been built. This will help to throw much of the rain off. See also the article on *COMPOSTS*.

Half-rotted turf can also be used for the above purposes. It is an ingredient of many potting soils or composts, especially for strong-growing plants such as Chrysanthemums, Tomatoes, etc., which need some strength in their soil.

Half-rotted turf is freely used for putting over the drainage crocks in potting to prevent the drainage becoming clogged with particles of fine soil. For this purpose it should not be cut up too small, and should be rammed down very firmly.

E. T. E.

TURF CUTTERS.—See *GARDEN TOOLS*.

TURK'S CAP LILY (*Lilium Martagon*). See *LILIES*, and under LILY in *WATER GARDEN: PLANTS FOR THE*.

TURK'S CAP LILY: SCARLET (*Lilium chalcedonicum*).—See *LILIES*.

TURNIP BEET.—The same as Turnip-rooted Beet.

TURNIP CABBAGE.—This is a name sometimes given to *Kohl Rabi*, which see.

TURNIP AND CABBAGE GALL WEEVILS.—See *Insect Pests.*

TURNIP FLEA BEETLES. — See *Insect Pests.*

TURNIP LEAF MINER.—See *Insect Pests.*

TURNIP MOTH.—See under Surface Larvæ in *Insect Pests.*

TURNIP RADISH.—A variety of Radish. See *Radish.*

TURNIP-ROOTED BEET.—See *Beet-root.*

TURNIP-ROOTED CHERVIL. — See *Parsnip-rooted Chervil.*

TURNIP-ROOTED CROPS. — See *Kinds of Crops.*

TURNIPS (*Brassica Rapa.* Nat. Ord. Cruciferæ). — Although of easy culture, these well repay generous treatment, the quality of roots grown with care in a garden being altogether superior to others of the same variety grown under field cultivation, or where a slip-shod method only is followed.

Culture. — Rapid growth is the secret of obtaining sweet, juicy turnips, and to ensure this, not only must plenty of manure be added to the soil, but this must be finely broken up, and the surface raked down very level.

Seed may be sown any time from early spring until the first week in September. The latter sowing will provide a good supply of roots all the winter, and if left in the ground instead of storing in pits or sheds, will throw an abundance of delicious green early the following spring.

The rows may be from 8–12 ins. apart, the latter only where the ground is very rich and bulbs of large size wished for.

Avoid making the seed drills too deep, since the seed needs a very slight covering of fine soil. Should a warm shower follow the sowing, the young plants may usually be seen through the soil in less than a week. Thin out to 4 ins. apart as soon as the plants show the rough or true leaf, and dust them over with old soot freely to check the Turnip Fly. Use the hoe very frequently between the rows, and whenever possible give a sprinkle of one of the better known artificial manures just previous to a storm. By the time the plants fairly touch each other, most will have formed a root of small but useful size. Each alternate plant may then be withdrawn, allowing those remaining a clear 8 ins., which distance invariably produces roots of the most acceptable size.

Large sowings are rarely advisable, the quality of the roots deteriorating after a certain stage is reached; and where good quality is the chief consideration we advise a small sowing to be made every fortnight from May until August, the sowing made at the latter date being a much larger one to provide roots for the winter supply.

When making sowings during the hottest weeks of the summer, pour water freely along the drills a short time before sowing the seed; and as soon as the little seedlings appear, sprinkle short grass or chaff over the tops to protect them from the Turnip Fly, which in some seasons ruins whole sowings where this or other precautions are neglected.

Varieties.—The following are excellent: — All the Year Round, Carter's Jersey Lily, Chirk Castle, Early Frame, Early Snowball, Green Top, Manchester Market, Red Globe. *All the Year Round, Chirk*

Castle, and *Orange Jelly* are the most suitable for sowing for winter use, and, being very hardy, may be left in the ground all the winter without harm, in a season when many others would be ruined.

F. R. C.

TURQUOISE BERRIED VINE (*Vitis heterophylla humulifolia*). — See *Climbing and Trailing Plants*.

TURRITES.—Now included in the genus *Arabis*.

TUSSILAGO (Nat. Ord. Compositæ).—Five species previously included in this genus are now referred to *Petasites*, on which genus we devote a separate article. The remaining species grown at Kew (*Tussilago Farfara*) is the Coltsfoot, a perennial weed spreading by thick whitish underground stems, quite unworthy of cultivation save for medicinal purposes. See articles on *Medicinal Herbs* and *Weeds*.

TUSSOCK GRASS (*Deschampsia caespitosa*).—See *Deschampsia*.

TUTSAN (*Hypericum Androsaemum* and *H. calycinum*).—See *Shrubs*.

TWAY-BLADE (*Listera ovata*).—See note at end of article on *Hardy Orchids*.

TWIN FLOWER.—See *Linnaea*.

TWINING BERCHEMIA (*Berchemia volubilis*). — See *Climbing and Trailing Plants*.

TWITCH and TWITCH-GRASS.—See under Bent Grass and Couch Grass in *Weeds*; see also *Agropyron*.

TYLENCHUS. — See Eelworms in *Insect Pests*.

TYPHA (Nat. Ord. Typhaceæ).

This is an unimportant genus of bullrushes and allied plants, more suitable for the wetter portions of the wild garden than for anywhere else.

T. angustifolia is the Small Bullrush, while *T. latifolia* is the better known Reedmace described under this name in our article on *Water Garden: Plants for the*. *T. Laxmanni* and *T. stenophylla* are other species which may be grown when space and circumstances admit. All bear brownish spikes of bloom in July each year, and average 3–6 ft. in height.

TYPHAENA.—See under Surface Larvæ in *Insect Pests*.

U

ULEX.—For the best species of this see *SHRUBS*.

ULMUS.—For the best species see *TREES*.

UMBELLIFEROUS CROPS.—See *KINDS OF CROPS*.

UMBILICUS.—Now included in the genus *COTYLEDON*.

UMBRELLA OF ST. JULIEN (*Populus tremuloides pendula*).—See *TREES*.

UMBRELLA PINE (*Pinus Pinea* and *Sciadopitys verticillata*).—See *TREES*.

UMBRELLA TREE (*Magnolia tripetala*).—See *CLIMBING AND TRAILING PLANTS* and *TREES*.

UNHEATED GREENHOUSE. — See *GREENHOUSE: COLD AND UNHEATED*.

UNICORN PLANT.

This, belonging to the genus *Martynia*, bears edible pods used in pickling. It is a climbing or trailing plant with yellow flowers, requiring greenhouse treatment, and is not greatly recommended for general culture.

UNIT VALUES. — See *ARITHMETIC AND GARDENING*.

UPRIGHT CROWFOOT.—See under *Ranunculus acris* in *RANUNCULUS: PERENNIAL BORDER SPECIES*.

URCHIN OF THE WOODS. — See EDIBLE FUNGI in *FUNGI: EDIBLE AND HARMFUL*.

UREDO STAGE.—See *RUST FUNGI*.

URINE: ITS USE IN THE GARDEN.

Gardeners do not realise as they ought to the immense value of human urine in the garden. In its fresh state the results gained from its use are often very disappointing, but after it has fermented for a few days, the food it contains becomes altered and much more valuable for plants.

In the limited cases where urine is used, it is the truth to say it is used the wrong way. Instead of the gardener making arrangements with the servants to save the urine and keep it separately for him, he goes down to the cesspool and pumps the liquid up to the garden again. Cesspool liquid (especially where the family is large and there are constant baths), is usually very poor, but in some cases it is wholly undesirable on account of the soapy matter it contains. Soap suds and human urine are not a good mixture, and frequently turn the soil sour.

The gardener should arrange that all urine made in children's nurseries and in the bedrooms be saved for him, and emptied into one of three barrels daily during the summer months. Thus a constant supply of fermented urine will be available, and the problem of not being able to get drainings from cow-sheds and pig-stys for making into liquid manure will be solved.

The barrels of urine should be out of sight. This can be managed by putting them behind a group of tall shrubs. But they must, nevertheless, be easy of access and in a convenient spot, since everything which can be done should be done to avoid unnecessary extra labour.

When required for use, a can should be dipped into one of the barrels and this should be filled about one-fifth of its capacity with the fermented urine. The can is then filled up with water. This is, generally speaking, a safe liquid manure for strong-growing crops, but as the strength of human urine is apt to vary somewhat according to diet, health condition of its producer, and

period of its passage, it is well to test the diluted liquid first by pouring some over the foliage of large-leaved weeds. If it should burn them, it is too strong, and should again be diluted. This liquid is splendid for such gross feeding crops as leeks and onions, also celery, all of which will stand a lot of feeding. This liquid may also be used, as mentioned just now, as a general liquid manure.

If the barrels should smell badly, it will be necessary to mix a small quantity of sulphuric acid with their contents, and this should stop the trouble.

Urine can be used in another way besides the one given above. Mixed with twice its own volume of water, it is a grand liquid for pouring over heaps of vegetable refuse which the gardener desires to enrich and hasten in decomposition. This subject is dealt with more fully in the article on *Vegetable Matter*, which see.

E.

URTICA (Nat. Ord. Urticaceæ). The several species in this genus of hardy herbaceous and spreading perennial plants are quite unworthy of cultivation. *U. dioica* is the well-known Stinging Nettle, a most troublesome weed, the young shoots of which may be eaten as spinach or made into nettle-beer. See article on *Weeds*.

USEFUL TOP-DRESSINGS.—See *Top-dressing*.

USES OF BAMBOOS.—See *Bamboos*.

USES OF HEATHS.—See *Heaths*.

UVULARIA (Bellwort. Nat. Ord. Liliaceæ).—This is a small and unimportant genus of hardy herbaceous perennials, six out of its nine usually grown species now being included in other genera. Of the remaining three, *U. grandiflora* bears purplish flowers, and grows 1 ft. high; while *U. perfoliata* and *U. sessilifolia* both bear yellow flowers and only grow half that height. All three species bloom in May and respond to ordinary border or rock border culture in light loam. They are best propagated by division of the roots in mid-March, which also is a good time to plant.

V

VACCARIA.—Now included in the genus *SAPONARIA*.

VACCINIUM.—For the best species see *SHRUBS*.

VACUUM BOTTLES. — These are used in FRUIT BOTTLING. See *FRUIT BOTTLING AND PRESERVING*.

VALERIAN (*Centranthus angustifolius* and *C. ruber*. Nat. Ord. Valerianaceæ). — This well-known wall garden, rock garden, wild garden, and perennial border plant must be distinguished from the GREEK VALERIAN (*Polemonium caeruleum*). It is quite distinct and belongs to a totally different Natural Order, in addition to which it is about as unlike a Phlox as a Dahlia is different from a Snapdragon. It is wanted as a drug, and is said to be so nasty that when a leaf is chewed melancholia is driven away to such an extent that one feels fit to jump over the moon with exuberance.[1] Sprays of the flowers are useful for cutting, and prove very showy in vases or bouquets.

Culture.—This is of the easiest. If left to itself the plant quickly seeds, and hundreds of young plants appear all round it. This is very desirable in the wild garden and on the wall garden, but in the herbaceous border care must be taken to remove the dead flower-heads immediately they are formed to keep the plants from spreading. Any ordinary garden soil and almost any position, though very preferably a dry, hot sunny and limy site, is suitable. Propagation is simple. The fleshy roots may be divided and replanted, or abundant stock may, as already mentioned, be raised from seed. Planting can be done from November to late March, at which time also division is successful. Seed may be sown in the spring or summer in the usual way, burying it lightly in ordinary sandy compost.

What to Grow.—Omitting the annuals, which are not often known as Valerians, and which are now but little grown and of small consequence, we recommend the following :—

Centranthus angustifolius. — This is a dark red or crimson free flowering sort blooming from the early summer onwards into July. Its height is about 2 ft.

C. ruber.—This is a brilliant red sort flowering for three months from June onwards. At times it will reach 1 yd. in height, but more usually it does not exceed 2 ft.

C. ruber albus.—This white variety is not nearly so attractive as the one above, though it blooms as freely and at the same time. It averages about 18 ins. in height.

C. ruber flore-albus. — This is *C. ruber albus* under another name, and is neither a distinct variety nor a species.

VALERIANA (Nat. Ord. Valerianaceæ).—This genus of plants is quite distinct from that described in our article on *VALERIAN*, although sometimes known by the same English name. It is a large but not very important family of hardy herbaceous perennials of which the dwarfer sorts may be used in the rock garden. *V. officinalis* is described under VALERIAN in our article on *MEDICINAL HERBS*, and our own medical

[1] We cannot vouch for the accuracy of this statement!—EDITOR.

man informs us he has prescribed it with very satisfactory results in cases of hysteria, especially in young girls. Valerian tonic is one of the worst-tasting medicines in the Pharmacopœia.

Culture.—The medicinal culture is fully described in the article mentioned above. Garden culture is not a matter of any difficulty. Ordinary garden soil and warm dry sunny situations suit the plants admirably. Propagation by seeds at the usual time (summer), and by root division in the autumn or spring, is quite an easy matter, and success may be anticipated and attained by planting in March.

What to Grow.—Only a few of the very numerous species can be described here; for others larger works must be consulted:—

Valeriana alliariaefolia.—This is a red sort blooming from June onwards, and growing 1½ ft. in height.

V. globulariaefolia is similar but only 1 ft. high.

V. officinalis.—This, popularly known as VALERIAN, or CAT'S VALERIAN, is fully described, as already mentioned, in our article on *MEDICINAL HERBS.*

V. Phu (CRETAN SPIKENARD).—This is a useful white sort blooming from July to August, and growing about 1 yd. in height. The yellow-leaved variety *V. P. aurea* is used for spring bedding.

V. pyrenaica (CAPON'S-TAIL GRASS).—This is a pretty pink species flowering from August to September, and growing 2–3 ft. in height.

V. supina.—There are both white and red forms of this July blooming species, which only grows 6 ins. in height.

VALERIANELLA (Nat. Ord. Valerianaceæ).—This is an unimportant genus of hardy annuals of little value for garden decoration. The best known species is *V. olitoria,* the CORN SALAD or LAMB'S LETTUCE, the culture of which will be found described under the former name in our article on *SALAD PLANTS.*

VALLEY OAK (*Quercus lobata*).—See *TREES.*

VALLOTA.—See *SCARBOROUGH LILY.*

VALONIA OAK (*Quercus Aegilops*).—See *TREES.*

VALORDIA.—Now included in the genus *CERATOSTIGMA.*

VALUATION OF MANURES.—See *MANURES.*

VALUE OF ALLOTMENT SOCIETIES. See *ALLOTMENT ORGANISATIONS: THEIR VALUE AND PURPOSE.*

VALUE OF ASHES.—See *ASHES: THEIR VALUE IN THE GARDEN.*

VANCOUVERIA (COLUMBIAN BARRENWORT. Nat. Ord. Berberidaceæ).—Only one species is known. This succeeds in shady situations, and is propagated by division of the roots in autumn or spring.

Vancouveria hexandra.[1]—A sort with elegant Thalictrum-like foliage. Flowers white, in panicles. Site, shade. Soil rich gritty peat. Flowering Period, May to June. Height, 9 ins.

VANDA.—See *ORCHIDS.*

VANILLA.—See *ORCHIDS.*

VAPOURER MOTH.—See *INSECT PESTS.*

VARIABLE BUDDLEIA (*Buddleia variabilis*).—See *CLIMBING AND TRAILING PLANTS.*

VARIEGATED GROUND IVY (*Nepeta Glechoma variegata*).—See *CATMINT.*

VARIEGATED MAIZE (*Zea Mays variegata*).—See *ORNAMENTAL GRASSES.*

VARIEGATED TREE MALLOW (*Lavatera arborea variegata.* Nat. Ord. Malvaceæ).—Seeds of this pretty biennial should be sown in a cold frame in April, the seedlings being transplanted and put out in

[1] This is the BARRENWORT of Kew.—EDITOR.

May; or seed may be sown outdoors at that time. The first method gives the largest plants, which have a striking sub-tropical appearance. The leaves are handsomely splashed with white. The purple flowers are produced on branching stems, 3–6 ft. high, from July to September in the second year. For other species of Mallow see articles on *Lavatera* and *Malva*, while for False Mallow see article on *Malvastrum*.

Vases.—See *Garden Furniture*.

VEGETABLE BOTTLING.

Experience has shown that vegetable bottling is not so easy as fruit bottling, and since vegetables contain different bacteria from fruits, different treatment and greater heat is required if they are to be successfully bottled. A difficult problem to solve is the retaining of the natural colour, and this can be done in the case of white vegetables such as Artichokes and Celery by exposing them to the fumes of burning sulphur, or in the case of Peas and Beans by the addition of a little carbonate of soda and borax. All vegetables must be bottled in vacuum jars, for it has been proved that jars with bladder or paper tops are quite unsatisfactory.

Below we give a few particulars of some of the ways of bottling.

Peas and Beans.—Shell the peas and have ready a saucepan of boiling water with a pinch of salt and a sprig of mint added. Boil the peas in this for two minutes, pouring straight into a colander and cool in cold water. Pack the peas tightly into bottles, filling to overflowing with the following mixture previously prepared and allowed to go cold:—

Boiling Water .	2 pints.
Powdered Borax .	2 teaspoonfuls.
Common Salt .	1 teaspoonful.
Carbonate of Soda .	1 teaspoonful.

Put on the glass lids and screw the metal tops down loosely, avoiding putting on the rubber bands. Place the bottles on a false bottom in a deep pan and fill up with cold water in the usual way. Bring to the boil and continue boiling for forty-five minutes without ceasing. Take each bottle out separately, unscrew the top and put the rubber band in position after dipping it into boiling water. Screw down the lid immediately, and allow to go cold. Next day loosen the metal screw slightly, and place the bottles in a pan of cold water, boiling them again for forty-five minutes and treating them as before. Repeat the process a third time, and if any liquid has boiled out of the jars, fill up each with boiling water from the kettle. The rubber bands are best removed during each sterilising. Broad Beans and French Beans are preserved in the same way, and this method is known as "intermittent sterilising."

Other Vegetables.—Nearly all other vegetables do not require sterilising more than on one day, and the bottles of these should be filled up with brine when cold, made of one pint of boiling water and one teaspoonful of salt. The lids are screwed down loosely without the ring in the usual way, but boiling for one and three-quarter hours is necessary. In the case of Carrots and Marrows it is often necessary to refill the bottles with boiling brine after the one and three-quarter hours' boiling in a pan.

Preparation for Bottling:—Asparagus.—None but that absolutely fresh should be used, and, of course, sticks of even size and of the length of the bottles should be selected. Wash them and pack them head upwards, using the same mixture recommended for Peas if the colour is to be kept.

CARROTS.—Young roots of these bottle well. First scrub them and boil for a few minutes, after which the skins are easily removed. Cut either into even lengths or rounds, and pack tightly into bottles; then proceed in the usual way.

CELERY.—This may be preserved similarly to Seakale. (See below.)

LEEKS.—Well-blanched, straight-stemmed leeks not too large are the best. Clean them thoroughly, cut them to fit the bottle, and pack tightly, after which proceed in the usual way.

MARROWS.—First peel these, removing the pithy part with the seeds, and cut into even pieces to fit the bottle. Pack tightly until quite full, after which proceed in the usual way.

SEAKALE.—Nice heads of this should be selected and, after thorough washing, cut into even lengths with the heads up, and pack tightly into the bottles. Fill up as usual with brine, and sterilise, adding a lump of sugar if a good colour is wanted.

Runner Beans in Salt.—This is another form of preserving, and is useful for large quantities of Beans. Stone jars of good size are the best, and after washing these a good layer of common salt is put in. The beans must be gathered before they grow tough, and be topped and tailed, after which they are laid flat on the salt in alternate layers. A thorough sprinkling of each layer of beans with salt is advisable, as also is a layer 1 in. thick on the top of the bottles. The beans may be sliced before putting in salt, if small jars must be used, and prior to use should be well soaked in cold water.

It may be pointed out in conclusion that vegetables preserved in vacuum jars should be tested twenty-four hours after bottling in the same manner as should fruit. (See article on *FRUIT BOTTLING AND PRESERVING.*) All bottles should be stored in a dry place away from strong light.

Time Required.—We give below the minimum times required for sterilising vegetables:—

Artichokes	1¾ hours.
Asparagus	Intermittent.[1]
Beetroot	1 hour.
Broad Beans	Intermittent.
Carrots	2 hours.
Celery	1¾ hours.
Dwarf Beans	Intermittent.
Leeks	1¾ hours.
Marrows	1¾ hours.
Peas	Intermittent.
Runner Beans	Intermittent.
Seakale	1¾ hours.

E. C.

VEGETABLE CAMELS. — A name applied to cactaceous plants. See *CACTI.*

VEGETABLE CULTURE IN CITIES.—See *TOWN AND CITY GARDENING.*

VEGETABLE MANURE.—See under GENERAL MANURES in *MANURES.* See also *LEAVES, PEAT, SEAWEED AS MANURE, VEGETABLE MATTER,* etc.

VEGETABLE MARROWS (*Cucurbita Pepo ovifera.* Nat. Ord. Cucurbitaceæ).—These usually prove a very welcome crop, and have the advantage of growing and fruiting in parts of the garden where many other vegetables fail.

They are distinct both in nature of growth, also in formation and colour of the fruits, while the fact that many fully grown specimens of some varieties each year are found to turn the scale at 60 lb. or more, while other fully grown fruits of another variety may not be above 5 lb. or 6 lb., shows the diversity of size and weight.

The long fruiting, trailing varieties enjoy the greatest popularity

[1] Intermittent sterilising signifies that more than one sterilising is required. All the vegetables marked in this way above should be sterilised for forty-five minutes up to a heat of 212° F., on three successive days.—EDITOR.

among private growers, and certainly the small grower, having an ugly fence or building, or anything objectionable, to cover cheaply and quickly, could hardly find anything better than this; but where nothing of this kind exists, and the call upon these as a vegetable is not likely to be a very frequent one, the Bush variety, so largely grown by market gardeners, is then more likely to give satisfaction.

Culture.—To provide fruit early in July, sow seeds the first week in April, and give the plants the protection of frame or greenhouse till May. For all ordinary purposes, the seed may be sown in the open air any time during May. (Late May is soon enough in cold, exposed, northern districts.—EDITOR.)

A good, rich rooting medium is at all times desirable, but it is quite unnecessary to go to the trouble of making the huge manure-beds one frequently sees in or near farmyards, which, although favouring the production of tremendous leaves, invariably give less weight and less fruit than is taken from plants where only a moderate quantity of manure is provided. We have found the best way is to prepare a trench exactly as advised for celery, allowing it to be a foot or more wider, and in this plant the seeds two or three together about a yard apart. Should more than one germinate, remove all but the strongest at once, and encourage a rapid growth by frequent waterings with tepid or rain water. If a long succession of fruit is desired, keep the plants in vigorous health by repeated applications of manure water, and cut all fruits before the skin becomes too hard to be easily pierced with the thumb nail.

Where huge fruits are more desirable than a larger number of others of moderate size, two or three should be selected as soon as "set" in July, and all others removed at once, the point of the shoots being taken out at the third leaf beyond the selected fruit. If these fruits are allowed to rest on pots or boxes high above the leaves of the plants, they will grow more rapidly than if covered by the huge foliage, and the ripened stage will be reached earlier in the autumn.

In addition to liquid manure, plants expected to give these large fruits should be liberally fed with one of the advertised patent manures, increasing the quantity as the specimens develop.

Varieties.—Splendid sorts for table include:—Custard, Hibbert's Prolific, Moore's Cream, Pen-y-byd, Perfection, and The Sutton.

For Large Size.—Carter Page's Mammoth, Long Green, Long White.

F. R. C.

NEW VARIETIES.

By crossing the ordinary kinds with the Custard Marrow several remarkably good varieties have been raised. Two of the best are:—

Rotherside Orange.—This bears round fruit, slightly flattened at the top and bottom. It is of medium size, very prolific, and of fine flavour. The skin of the fruit is pale brown when ripe, and the plant is of trailing habit.

The Melon.—This bears globular fruit suggesting a small melon. It is of medium size, very prolific, and of first-class flavour. The skin is greenish-brown when ripe, and the plant is of trailing habit.—W. J. C.

See also *CUCURBITA* and *ORNAMENTAL VEGETABLES*. For METHOD OF BOTTLING see *VEGETABLE BOTTLING*.

VEGETABLE MATTER.

Not very long ago the present writer read an article on "Green

Manuring in the Garden." This article, he was amused to see, confused hopelessly two different subjects, namely, Green Manuring and Vegetable Manuring. The former, as is clearly stated in the article on the subject in the earlier part of the Dictionary, is concerned only with digging fresh green live growing crops into the soil. Vegetable manuring, on the other hand, means digging into the soil rotted vegetable matter (which is not green at all); using this vegetable matter with or without artificial fertilisers. Thus gardeners should clearly distinguish between the two. True Green Manuring is highly valuable, but this is dealt with in a separate article.

Vegetable Matter is a comprehensive term embracing as it does all soft easily rottable garden rubbish. Leaves are also included, but most people prefer to save them separately, since they make valuable mould. (See *Leaves, Gathering, Storing, and Using.*) It embraces everything that is desirable and capable of rotting into humus, from weeds and cabbage leaves to dead stems of flowering plants. Clippings of shrubs and hedges, prunings from roses and fruit trees, also dangerous weeds such as nettles, dandelions, docks, goosefoot, coltsfoot, trefoil, twitch, buttercup, wild strawberry, ground ivy, etc., must not be considered as Vegetable Matter—these materials form what is more properly termed garden rubbish, and should be disposed of as described in the article *Burning Garden Rubbish.*

Vegetable Matter consists, then, of all soft, clean, valuable, rottable plant remains. Vegetable Manuring consists, first, of turning the vegetable matter into rich manure; and secondly, of the application of this manure to the crops and flowers. It is necessary to change it into manure first of all, since green rubbish which has been lying about for some time is not good, and usually contains many pests. When selecting material it is well to see that there is no fungoid disease on any of it, and for this reason potato haulm should never be used, as it nearly always carries spores of the ordinary potato disease (*Phytophthora infestans*), and frequently carries something worse as well.

To change vegetable matter into manure is sometimes no easy task, especially if the weather turns very hot indeed. We think that the quicker the first decomposition is within reason the better. The only thing to be guarded against is what is technically known among horticulturists as "foul fermentation." If this sets in the material becomes burning hot and turns white and mildewy. Animal manure is addicted to this dry rotting or dry heating as well as vegetable manure, and the remedy is to turn over the heap at once, shaking the matter well out to let off some of the rank gases, water very thoroughly, and then make the material into a very firm stack again.

There are several different ways of turning the vegetable matter into manure. A popular way is to make a stack above the ground and cover it with soil, letting the material remain undisturbed for a year. This, however, is not one of the best methods, but it has to be adopted if the water-level is near the surface. We consider the very best way is to have a large rectangular pit dug, some 6–10 ft. deep and the sides and bottom bricked or concreted. At the bottom of the pit there should be a grating leading to a small and still deeper hole. A pump should be connected with this latter hole, and periodically the liquid should be sprayed on to one of the upper layers

of material in the pit. This hastens its decay and greatly improves the quality of the manure. As the material is thrown in it should be sprayed with water, liquid manure, or, better still, urine from children's nurseries, bedrooms, etc. This will help it to decay and will also improve it greatly. The material should be trodden firm. It may be necessary to use gypsum to absorb ammonia, or chloride of lime to prevent unpleasant smell, but as little as will suffice should be used.

Unless the pit is of very large size it will become full long before the end of the season. This being the case its emptying becomes a matter of prime necessity. When the material is turned out, the top foot depth or so should be kept separate as it will not have decayed at all or only just have started. The rotted material should be well shaken out and mixed together, after which it should be built into a firm stack above ground, beaten hard, and covered with soil until required for use.

Some gardeners have what is called an "open bed" for the making of this vegetable manure. This is really a shallow hole. The material is thrown in and piled up. After about a fortnight these gardeners turn the whole lot of the material over and mix it together, thereby exposing a fresh surface to the drying action of the sun and wind. We consider this to be a great mistake, but, of course, it is absolutely necessary if the thermometer shows that the material has started to heat violently. If, however, the thermometer (which should always be stuck in the centre of any heap or pit of animal or vegetable matter which is rotting) does not show any undue rise of the temperature, the material should be left alone to decompose in its own way, thus saving time, worry, and trouble.

And now just a few words must be said about using the vegetable manure we have just made. If it is pure and simple rotted vegetable matter, and even if it is made with urine, it is much milder than the best farmyard manure. Thus it can be used in a larger quantity. We prefer to allow it to remain in the pit three months and then in the stack another six months, after which it is mild and harmless, though even so it is quite rich. About 4–5 cwt. per sq. rod of land can be used; a little less in the case of flowers perhaps, and a little more for the strongest vegetables. It can be dug into flower borders in the autumn, winter, or spring; it can be dug into the borders immediately prior to putting down summer or winter bedding; or, mixed with a small quantity of leaf-mould and rubbed through a half-inch riddle, it makes an ideal top-dressing for lawns, the grass of which is of poor quality. In the vegetable garden the first use of the fresher material which occurs to us is, as manure for celery and leek trenches, instead of animal dung. In the summer it can be dug in shallow, and surface-rooting crops sown on the land. In the winter it can be freely used in the trenching. It is not adaptable as is stable or cow dung as a mulch. For roses it is splendid, and good results have been attained by using equal parts of this and dung when making up borders for indoor fruits. These few remarks will serve to show how very useful vegetable matter is, and hence gardeners are urged not to burn the useful matter on the fire, which process is wasteful, but to keep it separate from the other matter and use it as manure.—E.

VEGETABLE OYSTER. — A name applied to *SALSAFY*.

VEGETABLES: Blanching and Forcing.—In catalogues of vegetables are a number which, to produce at perfection, require treatment, for a greater or lesser time, by blanching. This period, during which the plants are shut away from light, acts in two ways: firstly, forcing artificial growth, whereby a succulent and palatable product results; and secondly, blanching, by robbing the growths of the effects of colouring matter, and thus lessening a certain bitterness or high flavour appertaining to the healthy green natural growth, which renders the edible portion very much more suitable for table use.

There are, in different countries, many methods employed for blanching, especially amongst those clever gardeners of China and Japan, but as these items do not yet affect our daily menu here, it is only proposed to deal with the forms to be found in use in most gardens in this country.

Blanching is really only a method of forcing as exemplified in the case of the Leek, where the endeavour of the plant to reach light, when this is excluded, produces a length of blanched stem succulent and delicious in flavour. The principal vegetables we have to consider are Cardoons, Celery, Chicory, Dandelion, Endive, Leeks, Mushrooms, Rhubarb and Seakale.

Cardoons.—On the Continent these are more largely grown than here, and we do not know them so well as we should, for they are very useful in giving a change of vegetable during autumn and winter. The most satisfactory way of growing is like Celery, in trenches prepared about the end of March or beginning of April. To blanch, use brown paper, commencing about eight to ten weeks before required for the table, and use in addition hay-bands for protection purposes. Wind a strip of the paper, about 6 ins. wide, round the plant, first securing the leaves together by tying with raffia at the top, also securing the plant itself to a stout stake. Round the brown paper wind a hay-band, and earth up. Repeat in about ten days until the operation is finished. If sharp frosts threaten, protect the whole with straw or bracken. See also paragraph on *Cardoons* in body of work.

Celery.—The blanching of this vegetable can be done in two ways. Early supplies, grown on the flat, can be blanched by tying up in brown paper wrappings, using moderately stiff paper in bands about 5 ins. in width, fastened round the plants with two or three secure ties of raffia. Draw the soil round the base, and, at intervals of about ten days, add further bands until within about 6 ins. of the growth.

For winter supplies, earthing-up is necessary. The day before doing this, give the plants a good soaking with water. Break the soil up finely before putting round the plants, and one worker should do the earthing-up whilst another should hold the growths compactly together, to keep the soil from working in. Remove any side-growths before earthing-up. Moulding-up should be done in stages, putting about 6 ins. of soil round at a time, and allowing about ten days to elapse before repeating. The Celery planted out for very late supplies should not be earthed up until the autumn is well advanced, as it will then prove more frost-resistant. If severe frost threatens, cover over the top and ridges with straw, bracken, or similar material. See also article on *Celery*.

Chicory.—This is a useful winter and spring salad medium, though some like it boiled as a vegetable. Its general culture is dealt with elsewhere in our article on *Salad Plants*. To force it, lift some of the plants in the open ground about three weeks before they are wanted for use, remove the foliage just above the crowns, planting closely together in a box, and cover over with fairly moist fine soil. Stand in a cool, frost-proof cellar, or similar place, from which light is excluded, give an occasional syringing with tepid water, and a good quantity of blanched leaves for salads will be obtained, which are most useful when Endive and Lettuce are very scarce. The other plants can be lifted and similarly treated to maintain supplies.

Dandelion.—Another useful salad material, of which there are now varieties improved over the common field type for garden growing. It should be raised in the same way as Chicory, and at the same time. For winter use lift as required, and blanch in the way recommended for Chicory. For spring use it can be blanched where it grows by placing sufficiently large pots over the plants. See also article on *Salad Plants*.

Endive.—A member of the same family as Chicory, and even more useful for salads. There are two forms, the Batavian or large-leaved, and the curled. The general culture is described elsewhere in our article on *Endive*, but in the present article we are concerned with its blanching.

To do this thoroughly for table use, in order to lessen the bitterness of its flavour, in summer and autumn we can effectively accomplish it by tying the leaves loosely together, taking care to leave sufficient room for the young leaves to grow; also it can be done by placing a large pot over the plant, with the drainage vent closed. The most satisfactory plan to blanch in winter is to lift a few plants at intervals, sufficient to meet requirements, and place in a cellar or similar dark place.

Leeks.—These are best raised in the manner described in the separate article on *Leeks*.

Growing in trenches, similar to those advocated for Celery, is the way to obtain the best results, though where this cannot be done they may be grown on the flat, or in holes bored with an iron bar.

Blanching must be proceeded with from the time the plants are first put out. Brown paper tubes, about 6 ins. in length, are best for this work, and should be placed round each plant, and a little soil drawn about the bottom to keep it in position, using also two small sticks to give support to the tube. Examine the plants every week or so, and as they draw up, raise the tube, replacing it with a quantity of soil round the exposed portion of the blanched stem, until about 12–15 ins. of blanch is attained.

Mushrooms.—Although, strictly speaking, blanching is hardly done in the case of Mushrooms, it is necessary to include them in these notes, as undoubtedly the best results are obtained by growing in the darkness of a cellar or mushroom-house, owing to the atmosphere remaining more moist and of more equable temperature. (See article on *Mushrooms*.—Editor.)

Rhubarb.—Forcing Rhubarb is essential to obtain early supplies. The plants should have two seasons' growth prior to forcing, and early varieties only must be selected for earliest supplies. When the leaves die down in autumn, lift the stools and place under a north wall for

about a fortnight, covered by straw, litter, etc., then place in the warmest end of a mushroom-house, a warm pit, or a cellar, with sufficient soil round the roots to cover them. Two or three batches can be forced in this manner for carrying on the supply, and after these are finished, cover over some of the stools in the open with pots, or tubs, of sufficient size, and place over and around these, leaves which are starting to decay, or similar material, to raise the temperature to about 55° F. See also our article on *Rhubarb*.

Seakale.—The forcing and blanching of Seakale may be commenced about the middle of November. Select as far as possible plants of two years' growth for this purpose, and invert a seakale-pot over each group of crowns, first clearing the ground of rubbish and placing a good mound of ashes over the crowns; also lightly fork over the surface of the ground. Over the pots should be put good leaves, in order to raise the temperature to 50–55° F. as the leaves begin to decay and ferment. It is necessary to keep out light and air, but, as the weather gets warmer and the season advances, less leaves will be necessary.

Latest supplies from permanent beds (see article on *Seakale*) should be ridged over with light soil, ashes, or both mixed, and as the growths aim to reach light and air, they will be ready for cutting when the ridge material shows signs of cracking owing to the shoots starting to grow out. If necessary to cut before required, Seakale will keep for some time stood in a little water in a cool dark place.

When the forced crowns are cleared, they should be covered with ashes, the ground surrounding them being first dressed with manure and this forked in.

Another satisfactory way of forcing Seakale is to lift the crowns at intervals as required, and place them in the warmest end of the mushroom-house or cellar. Syringe the crowns occasionally, and keep perfectly dark. This may be practised all through the winter months.—Ed. B.

VEGETABLES: Diseases of.—The articles containing notes on the various vegetable diseases are referred to in *Vegetables: General Considerations*.

VEGETABLES: Drying of.—See *Drying of Fruits and Vegetables*.

VEGETABLES: Exhibition Culture of.—See *Exhibition Vegetables*.

VEGETABLES FOR THE VERIEST AMATEUR.—See *Gardening for the Veriest Amateur*.

VEGETABLES: General Considerations.—Vegetable gardening is of such enormous importance that we feel that a special article on General Considerations must be included, although separate articles on almost all known vegetables have been already given.

Selection of Site.—More importance should be given to this than has been done in the past. Previously it was the opinion of garden designers that the best part of the garden should be kept for flowers. An inferior site, often not fully exposed to the sun, was considered good enough for the vegetable garden. There were sometimes, too, other disadvantages. The site was on a slope, and thus difficult to work; or the soil was thin and poor. The present writer, who has grown food during the war and for a lengthy period prior to the war, is of the opinion that the best possible position should be selected for the vegetable garden, as vegetables

are in many cases of greater importance than flowers.

Thus the site for the vegetable garden should be in as open a spot as possible, away from trees, and certainly not on a steep slope. The soil should, in the ideal vegetable garden, be a rich loam, and should be at least 2 ft. deep. It should rest on a semi-pervious bed, such as chalk marl, since neither an easily drained sand nor a stiff clay subsoil is ideal for working. However, if the site is not ideal in this respect, it will be necessary to improve the soil in the manner afterwards described.

Soils and Manures.—The opinions of vegetable gardeners are divided as to whether a light or a strong soil is the better for vegetable gardening. The ideal is, as we have said, a rich loam, but if the soil is strong and rests on clay, it is less expensive to reduce it to a suitable condition for vegetable growing than in the case of a very sandy soil. The first thing to do in making a vegetable garden is to trench the whole of the site 3 ft. deep if possible, turning the top soil 2 ft. deep, and breaking up the subsoil to a depth of 1 ft. Where, however, the subsoil comes to within 1 ft. of the surface, bastard trenching must be employed. This is a kind of false trenching, where the top soil is simply moved forward and not buried 2 ft. deep. Trenching is fully described in our article on *Soil Cultivation*. This work should be done whatever the nature of the soil may be, but if the soil is light, the manures used will be cow or pig dung, whereas if the soil is heavy, strawy stable manure will be far preferable. In digging the vegetable garden, care should be taken to mix the manure with all sections of the soil, except the 9 ins. immediately below the surface. The advice to manure the ground in the form of layers, that is to say, to put in a layer of manure at the bottom of each trench, is not a good plan, and frequently results in fanged roots.

The best time to manure the vegetable garden must now be considered. Where the ground is strong, manure should most certainly be applied in the autumn or early winter, the ground being left as rough as possible, and the digging completed as early after the end of October as can be managed. This will improve the tilth of the soil enormously, more than any gardener who has not seen it will believe. In the case, however, of sandy soil, manure applied so early will simply be washed through by the winter rains. In this case it would be advisable to give the ground a good dressing of chalk or chalk marl at the beginning of October, putting the material on in the form of rough lumps, and to delay manuring until mid-February or thereabouts, sowing almost immediately after manuring has been completed.

Artificial Manures.—Having now disposed of the question of animal manures, in connection with the soil, we must say a word or two on the question of artificials. Of course different artificials are needed for different crops; for instance, Peas need no Nitrates, Cabbages need no Phosphates, and so on. But, as a general rule, it is safe to say that heavy soils should be manured in the autumn or early winter, with such materials as Basic Slag, Cyanamide, Kainit, or Wood Ashes; and that light soils should be manured in the autumn with Bone Ash, Fish Meal, Flue Dust, or other similar semi-insoluble manures. Again clay soils should be manured in the spring and early summer with such fertilisers as

Sulphate of Ammonia, Sulphate of Lime, and so on, and light soils should be manured in the spring with such easily soluble manures as Salt, Nitrate of Soda, Potash manures, etc. Manures such as Guano, Dried Blood, Nitrate of Lime, and Nitrate of Ammonia, all of which are highly soluble in water, are useful for any kind of soil, but they should not be applied except during the growing season in the spring and summer. Dissolved Bones, Superphosphate, Sulphate of Ammonia, and other acid manures are useful for chalky soils containing excess of lime. These soils invariably produce scabs on potatoes. Old rich garden soils which have been manured for many years are often more or less sour, and for these soils, manures of an alkaline character such as Bone Ash, Calcium Cyanamide, or even Quicklime and Wood Ashes are more suitable than any others. Acid manures, such as Sulphate of Ammonia, Superphosphate of Lime, Dissolved Bones, and Dissolved Guano, should be avoided, with others of a similar character, as they will be useless for producing good crops on such soils.

General Management. — The special culture required by each vegetable is dealt with in the article on that vegetable published in the Dictionary, but a few general hints are appended :—

Thin Sowing.—This is most important if the crops in the vegetable garden are to be a success. Thick sowing is common, and produces more poor crops than anything else. In our articles the distances that should be left between the drills are usually indicated, and the advice there given should be strictly followed, as the writer on each vegetable is a practical gardener of many years' standing, who knows how much room crops require. Instead of sowing the whole packet, it would be much better to drop three or four seeds in along the drills at intervals of a few inches, as it stands to reason that the plants have a better chance then, than if they are crowded together with hundreds of seedlings in a few feet of drill.

Thinning of Crops.—If thin sowing is practised, very little thinning will be required, but where this is necessary it should be done early. The correct distances for thinning out are given under the vegetable concerned, and, needless to say, a day when the soil is wet should preferably be chosen for the work.

Planting Out.—Crops of the Cabbage family need to be planted out, the most important points of this operation being to plant them extremely firmly in well-worked soil. It is a common fault to plant vegetables much too close together, to attempt, in fact, to grow three or four plants in the room sufficient for one. A practical man realises the folly of this method of procedure, and will keep to the planting distances which are named in the articles on each vegetable. Watering after planting is most important, it being inadvisable in the summer to trust the Clerk of the Weather to send rain the same night.

Hoeing of Crops.—How many gardeners realise the enormous advantage resulting from the use of the hoe between food crops? Certainly not 10 per cent. of them, or else we should not see weed-strewn vegetable gardens as we do. Certainly the hoe is one of the most valuable tools that the vegetable gardener can possess, and why he takes the trouble to purchase one and allows it to rust in his potting-shed, crying for use, is a question which we will not attempt to answer.

Hoeing stimulates the growth of the crops enormously. It also protects the under soil from undue evaporation, thus acting in a similar manner to a mulch, in addition to which it kills enormous quantities of weed seeds and of pests which may be lurking on the surface, such as cockchafer grubs. The present writer favours the regular use of the hoe at least once a week between all rows of standing vegetable crops, and he is of the opinion that were this done, many hundreds of tons of food we now waste would be available for the supply of the nation. Hoeing is also useful as a means of incorporating fertilisers with the land. For instance, Nitrate of Soda is sprinkled on the land amongst cabbage crops and hoed in.

MULCHING.—Mulching is of great importance in the case of Peas, Beans, and Cauliflowers. It is hardly applicable in the case of Cabbages and Potatoes, of which thousands of plants are grown yearly in the vegetable garden. Mulches, however, should be more used than they are, owing to the fact that they obviate the need of watering. A mulch, as explained elsewhere, consists of a light layer of material put on the surface of the soil, after it has been well watered, to conserve the moisture. The chief of the materials that are used for this purpose in the vegetable garden may be mentioned: Lawn Mowings in a fresh or rotten state, Cow Dung in a fresh or rotten state, and Spent Hops. Vegetable refuse in a rotten state is also used, as are leaves, but they are not so useful. The writer favours the application of mulches early in the season, before the soil has become really dry underneath, as this means that less watering will be needed before the mulching. The idea that mulches keep the roots of the plants too cold is a fallacy, provided that the mulches are not of inordinate thickness. Three inches is the most that should ever be put on at a time.

WATERING. — Watering in the vegetable garden is a vexed problem. Personally, the writer considers it is necessary only in special cases. If mulches are applied immediately after rain, very little watering will be required, but such crops as Celery, Peas, Runner Beans, and the like, which are exceptionally thirsty, will need watering in almost every season, however much rain there may be.

Again watering cannot be dispensed with altogether, since crops which are newly planted must have water to settle the soil about their roots, and to enable them to recover from the check to growth they have sustained. The general watering, however, of such crops as Beetroot, Cabbages, Kohl Rabi, Parsnips, Spinach Beet, Swedes, Turnips, and so on, is not to be recommended, and indeed is absolutely unnecessary if the soil has been properly worked at the start. Nor is mulching recommended for these crops. Surface crops, such as Lettuce and Spinach, cannot be grown without water, and if the season is dry they should have a thorough soaking every day, otherwise they will not be worth eating. The question of applying water is thoroughly dealt with in our article on *WATERING*.

WEEDING.—Of very great importance is the matter of weeding vegetables. We have already mentioned that the weeds should be got under early in the year by the frequent use of the hoe. This should be first plied between the rows, as soon as the seedlings can easily be seen, and in the case of potatoes as soon as the little shoots appear on the surface of the ground. How-

ever, it may be that the garden becomes weedy after the gardener returns from his ten days' holiday in July, and that is the most critical time of all. At once a start must be made to get up the weeds. Annual weeds can easily be pulled up by hand, but strong-rooting perennial weeds will have to be lifted with a little fork, otherwise much of their root system will remain in the ground and give further trouble. Perennial weeds should certainly be burnt. The others which are not in seed may be made into vegetable humus, as is explained in the article on *Vegetable Matter*. Every effort should be made, especially at the end of the season, to prevent any weed from seeding, since this means much more trouble next season. The special weeds with which gardeners have to contend are dealt with in an article on *Weeds*, where a method of controlling them is also given.

Rotation.—This is of some importance to vegetable gardeners if good crops are to be obtained. It is dealt with in a special article on *Rotation of Crops and Double Cropping*.

Feeding.—This too is a matter of importance to the vegetable gardener. The usual liquid to apply is made up by putting a peck of fresh horse dung and a quarter of a peck of soot into a 40-gallon barrel of water, allowing it to stand about a week, then drawing off the liquid. Great care should be taken, however, that no crop receives the liquid too strong. It should be diluted until it is the colour of pale ale, or weak tea, and applied after watering in dry weather, or after there has been a shower. Various artificial fertilisers can be used, and where a crop requires a special fertiliser this is mentioned in the article on that crop. Care must be taken not to over-feed, or the results will be the opposite of those desired. It may be pointed out, that such crops as Onions and Leeks can stand a great deal more food than any other crops, and that it is hardly possible to over-feed them.

Pests and Diseases.—The vegetable gardener has to contend with a great many pests and a large number of diseases. We cannot even enumerate a list of these here, but must refer the reader to our articles on *Insect Pests*, *Slugs and Snails*, and *Garden Enemies*; and *Diseases of Plants* for diseases. Where a crop is infested with a number of diseases, as for instance is the potato, these form the subject of a special article; thus we have *Onion Diseases*, *Potato Diseases*, and so on. It should be urged upon every gardener that when a disease is noticed, however small or slight the attack may be, steps should immediately be taken to control or cure it, otherwise the disease may spread and ruin the whole of a promising batch of crops in the garden.

Varieties.—The number of varieties of each crop is almost legion, and it tends to increase year by year. Obviously, however, it will be a great mistake to attempt to include anything like a complete list of the varieties of each crop in this Dictionary, since many of them are the same variety under a different name. It is to be hoped that there will be a good deal of standardisation of names, as soon as attention can be turned by seed specialists to this, and that a standard list of vegetables will be issued at no very distant date. However, for our purpose we have included a list of the most desirable varieties, at the end of the article on each vegetable, and we append now a selection for light soils and heavy soils, which

we hope will be useful to readers. It should be borne in mind that although when conditions are made favourable, each of the vegetables dealt with in these pages can be expected to give a profitable return for the labour expended, that not every variety of any particular vegetable is suitable for all soils. What gives good results when sown on a deep friable loam often proves a complete failure when cultivation is attempted on a poor sandy soil or a stony shallow one. In such cases experience alone is the safest guide. But the list below, although some may wonder at the inclusion of old-fashioned, well-tried varieties, consists in our opinion of the best sorts for heavy and light soils. In this selection the main consideration has been utility.

SELECTION FOR LIGHT SOILS.

Asparagus.—Connover's Colossal, Palmetto.

Beans (Broad).—Aquadulce, Enormous Hangdown, Giant Windsor, Harlington Green, Kinver Monarch, Knight's Tremendous.

Beans (Dwarf).—Canadian Wonder, Centenary (Golden), Dutch Brown, Earliest of All, Early Forcing, Everbearing, Golden Butter.

Beans (Runner).—Best of All, Exhibition, Prizewinner.

Beetroot.—Bell's (Non-Bleeding), Blood Red, Burpee's Black, Dobbie's Purple, Nutting's Dwarf, Volunteer.

Borecole (Kale).—Asparagus Kale, Dickson's Favourite, Dwarf Curled, Improved Hearting, Sutton's A1, Tall Curled.

Broccoli (Heading).—Adam's Early, Early Feltham, Eastertide, Edmonton, Last of All, Late Giant, Model, Self-Protecting, Snow's Winter White.

Broccoli (Sprouting).—Christmas or Extra Early, Green Sprouting, White Sprouting.

Brussels Sprouts.—Cambridge Champion, Dalkeith, Darlington Dwarf Gem, Exhibition, Matchless, Solidity.

Cabbage (August Sowing).—April, April Queen, Challenger, Defiance, Ellam's Early, Emperor, Flower of Spring, Harbinger.

Cabbage (Savoy).—Best of All, Early Tom Thumb, Green Curled, Latest of All, Perfection, Sugar Loaf.

Cabbage (Spring Sowing).—Early Rainbow, Early York, Express, Mein's No. 1, Nonpareil, Primo, Winningstadt.

Carrot.—Altrincham Selected, Early Gem, Early Nantes, Red Intermediate, St Valery, Scarlet Perfection, Summer Favourite.

Cauliflower.—Autumn Giant, Early Giant, Eclipse, Emperor, Magnum Bonum, Snowball, Standwell, Supreme.

Celery.—Aldenham Pink, Bibby's Defiance, Clayworth Prize, Standard Bearer, Superb Pink, White Gem.

Cucumber (Outdoor).—Japanese Climbing, Perfection, Pershore Long Ridge.

Endive.—Large Ruffec (new), Moss Curled, Paris White.

Kohl Rabi.—Early White, Sander's Small Top.

Leek.—Dobbie's Champion, Emperor, International Prize, Lyon, Prizetaker, Royal Favourite.

Lettuce (Cabbage).—All the Year Round, Favourite, Ideal, Lord Kitchener, Sutton's Magnet, Webb's Wonderful.

Lettuce (Cos).—Bath Cos, "Black Seeded," Crystal Cos, Exhibition, Hardy White, Jumbo, Kingsholm, Sugar Loaf.

Onion.—Ailsa Craig, Denver's Yellow, Excelsior, Exhibition, Improved Banbury, Magnum Bonum, Premier, Rousham Park Hero.

Parsnip.—Elcombe's Improved, John Bull, Lisbonnais, New Century.

Peas.—Autocrat, Capt. Cuttle, Carter's Michaelmas, Duke of Albany, Eureka, Glory of Devon, Ideal, John Howard, Laxtonian, Little Marvel, Perfection, Peter Pan, Rearguard, Rentpayer, Supreme, The Gladstone, The Lincoln, Thomas Laxton, Triumph, Walker's Perpetual.

Potatoes.—Arran Chief, Balmoral Castle, Dobbie's Favourite, Dobbie's Prolific, Drummond Castle, Golden Wonder, Guardian, Harbinger, King Edward VII, May Queen, Ninetyfold, Queen Mary, Ringleader, Snowdrop, The Chapman, Windsor Castle, Witch Hill Seedling.

Spinach.—New Zealand, Perpetual or Spinach Beet, Victoria.

Tomatoes (Open Air).—Cooper's First Crop, Evesham Wonder, Kondine Red, Market King, Recruit, Sunrise, Tuckswood Favourite.

Turnip.—All the Year Round, Early Marvel, Golden Ball, Green Top, Jersey Lily, Laing's Swede, Model, Snowball.

Vegetable Marrow.—Custard Marrow, Hibberd's Prolific, Muir's Hybrid, Pen-y-byd, Sutton's Perfection, The Sutton, White or Green "Bush" varieties.

SELECTION FOR HEAVY SOILS.

Asparagus.—Same as recommended for light soil.

Beans (Broad).—Bunyard's Exhibition, Eclipse, Exhibition Longpod, Green Giant, Johnson's Wonderful, Seville Giant Longpod.

Beans (Dwarf).—Canadian Wonder, Hundredfold, White Haricot (also others recommended for light soils).

Beans (Runner.).—In addition to those recommended for light soils, Champion, Emperor, Hackwood Park, White Giant.

Beetroot.—Acme, Cheltenham Green Top, Crimson Ball, Dobbie's Purple, Pine Apple, Pragnell's Exhibition.

Borecole.—Same as advised for light soil.

Broccoli.—Backhouse's Winter, Eastertide, Grange's Autumn White, Late Queen, Leamington, Ryder's June, Xmas Heading Purple.

Broccoli (Sprouting).—Same as advised for light soil.

Brussels Sprouts.—Those recommended for light soils are suitable.

Cabbage and Savoy Cabbage.—Same as advised for light soil.

Carrot.—Early Gem, Long Red Surrey, Model, Prizewinner, Sutton's Favourite, Webb's Defiance.

Cauliflower.—Same as advised for light soil.

Celery.—Same as advised for light soil.

Cucumber.—Japanese Climbing, King of Ridge, Stockwood Imp.

Endive.—Broad Leaf Batavian.

Kohl Rabi.—Early Purple, Early White, Sander's Small Top.

Leek.—Selections as for light soil.

Lettuce (Cabbage).—All the Year Round, Ideal, Lee's Immense, MacHattie's Giant, May King, Reliance, Wonderful.

Lettuce (Cos).—Balloon, Crystal Cos, Jumbo, Leviathan, Paris White, Perfect Gem, Vaux's Self-folding.

Onion.—All varieties mentioned under light soils are suitable.

Parsnip.—Elcombe's Improved, Hollow Crown, John Bull, Magnum Bonum, Tender and True, The Student.

Peas.—Autocrat, British Lion, Centenary, Duchess of Albany, Duke of York, Essex Star, Gradus, Hercules, King George, Late Queen, Peerless, Rearguard, Senator, Sharpe's Standard, Stourbridge Marrow, Telegraph, Telephone, The Daisy, The Daniel, The Gladstone, The Lincoln, The Pilot, Veitch's Perfection.

Potatoes.—Abundance, Arran Chief, Balmoral Castle, British Queen, Dobbie's Favourite, Epicure, Express, King Edward, Langworthy, The Admiral, The Crofter, The Factor, What's Wanted, White City.

Spinach.—Any variety offered in trade catalogues may be depended upon to give good results from heavy soils.

Tomatoes.—Same as for light soil.

Turnip.—Any variety offered in trade catalogues.

Vegetable Marrow.—Long Green, Long White, Moore's Cream. Also the White or Green "Bush" varieties.

F. R. C.

VEGETABLES: Harvesting and Storing.—The great general principle of harvesting and storing vegetables is "care." Care as to the crops being ready for lifting, care in lifting, care in preparation for and in actual storage, and care as regards persistent inspection after storage.

It will not be possible in the limited space at disposal to make full remarks on all the root-crops concerned, but we begin with a general discourse on

POTATOES.—By October the haulm of these will have died down somewhat, but if it has not, cut it down except in very late crops. Test the crops by digging up a plant, and if the tubers are plentiful and ripe, have them up. A good sign of ripeness is, that the skin on the tubers is set. But potatoes which are just right for eating must remain

in the ground a few weeks longer if they are going to be stored. Still, do not err, as a writer has said, by leaving the tubers in the ground "to swell" long after the haulm has died down; lift them and get them stored.

Lift the tubers with a fork, "making it a point of honour not to spear a single one." For our own part we like to use a rather large fork for this work, and it is inserted well below the approximated range of the tubers. Then collect the tubers into baskets, making sure by successive forkings that none are left in the ground, and great care should be taken that no diseased or damaged specimens are included.

A very good way is to store the tubers in a "clamp." Scores of our readers will have watched a farmer building a clamp, but we briefly describe this as follows:—

Begin by putting a thick layer of straw on a piece of level ground. On this build up successive layers of tubers and straw in the form of a long, triangular ridge. Cover the whole with several inches of straw, and then bank up all over with soil, making very firm.

Some store in heaps covered and interspersed with sand. Again, others store their potatoes in heaps in dark sheds or in boxes, or in layers on the floor of such sheds, covering as a protection from frost by a mat or straw. Many other root-crops may be effectively stored in clamps, for instance, carrots, parsnips, and turnips.

Having said the above about Potatoes, we now proceed with a list of other root-crops in alphabetical order.

ARTICHOKES (*Jerusalem*).—The Jerusalem variety of these is, no doubt, by far the most grown, so we deal with it only. Cut down the plants any time between the end of October and November, and fork up the roots as required for use. Many, however, like to store their Jerusalem Artichokes. After sorting them carefully, bury the lot in a heap of yellow sand, ashes, or even earth. At all costs the light must be kept from these tubers, as if they are not kept in the dark they turn colour, and are not nearly so nice looking when served on the table. Besides this, frost should be kept out of the shed in which they are stored. If not buried, mould will set in and the tubers will be spoilt.

BEETROOT.—This requires extreme care in the lifting. Use a fork, and on no account damage the roots the slightest or they will bleed badly and become useless. Your care cannot be too great. The tops should be gently twisted off. Do not, however, touch the crown. Beetroot is certainly a difficult vegetable to deal with. If it can be eaten at once, so much the better; if not, lift before frost, storing in sand in a cool shed, protecting from frost with straw.

CARROTS.—These must be lifted before frost with the fork carefully, and the roots should not be speared or broken. If there be any undesirably thin tap-root, however, cut this off and remove the "tops." Store in a moderately dry shed, protecting the heap from frost with mats or straw, removing these coverings in all cases as soon as the danger is past; or store in the clamp already described.

LEEKS.—These are hardy things, and after they have been somewhat earthed up may remain without protection all the winter, and be dug up as needed. Some put a thick layer of manure or straw around them to protect from frost, but we think this is quite unnecessary. Leeks may be stored in a shed under cover in sand, as also may *CELERY*, or they

may be kept for a long time during the winter "laid in."

ONIONS.—These should be lifted on a sunny morning and left lying on the ground till the early afternoon, or, if the weather be good, for a few days. This is done when they are sufficiently ripe in September, the necks having been previously broken a month earlier if necessary. They are stored, when dry, by tying in bundles and suspending from pegs or pothooks in the garden storeroom. Keep them dry.

PARSNIPS.—Very little in the way of harvesting and storage is needed for this crop. In our opinion it is better left in the ground right through the winter, and forked up in the winter months when required for immediate use on the table. It is better after frost. If, however, it be desired to store it, get to work with the fork, but, above all, leave plenty of room, or the roots will be damaged. Trim off the tops and store in sand in a cool, darkened shed. *SALSAFY* may also be treated in the ways advocated above.

TURNIPS.—These can be got in when large enough, and this is usually done in September or October. They are forked or pulled up, and the tops cut off, some little further consideration being given by the gardener than by the farmer to this operation. The tap-root, if of any size, is usually cut off, and the roots stored in a darkened shed under mats or in a clamp. The same applies to *KOHL RABI*, if it be desired to store the roots of this, the tops being first cut off, and the best of them eaten after being boiled. *SWEDES* may be conveniently stored in a corner of a cellar or outhouse under a mat or old carpet, extra covering being afforded in very cold weather.

E.

VEGETABLES: PESTS AND DISEASES OF.—The articles containing notes on these matters will be found referred to in *VEGETABLES: GENERAL CONSIDERATIONS.*

VEGETABLES: SAVING SEED OF.—See *SEED SAVING.*

VEGETABLES: TRANSPLANTING.—See *TRANSPLANTING.*

VEGETABLES UNDER GLASS.

Not the least important function of the hothouse, the warm pit, the frame on a mild hotbed, and the cold frame, nowadays, is the raising of vegetables, and not only the raising of seedlings, but the bringing of them to maturity also under glass. Time was when the hothouse was chiefly used for cultivating fruits requiring furnace heat to bring them to perfection, or for the growing of ornamental subjects such as Begonias, Orchids, Palms, etc.—plants that our climate would not permit to realise their full beauty, or was not sufficiently warm even to allow them to grow at all in the open. Modern demand for increased vegetable food and early supplies has changed all this, and now the production of vegetables under glass is nearly as important as is their outdoor culture.

In dealing with this subject, such items as cucumbers, marrows, and tomatoes will be left out, forming as they do an important group which is dealt with under separate headings throughout the work. These items, however, comprise only a small minority of the many kinds of vegetables that can profitably be raised under glass.

Much of our early vegetable supply has hitherto been imported from countries with warmer climes than our own; but there is no reason why we should not depend almost exclusively upon our own efforts, and produce in this country practically

all that is required for home consumption. Much could be done in both private and trade gardens in such a direction where there is glass, and the quality of home-grown early supplies should always be equal to, and in many cases superior to, the imported article.

The subject may be divided under three headings :—

(1) Raising vegetables under glass to maturity ;

(2) Growing under glass and maturing in the open ; and

(3) The raising of seedling vegetables for planting out.

No gardener should count himself really efficient until he can attain complete success in all three directions.

The Use of Boxes.—In connection with this method, whether the plants are to run their course wholly under glass, or are to reach their zenith in the open air, in all cases the box system is undoubtedly the best. It is one of the most useful ways of growing vegetables, the idea being the employment of deep boxes ; and no matter how large or small the available glass space may be, it proves its utility. One of the most convenient sized boxes is one measuring 30 × 10 ins. and 9 ins. deep ; the best thickness of wood for the purpose is 1 in. thick for bottom and ends and ½ in. thick for the sides. Any handy person can construct such a box, and when finished it should have the bottom perforated with holes of sufficient size to permit free drainage, namely, not less than ¾ in. in diameter. A strip of wood 1 in. square nailed along the top of each end affords means for lifting the boxes conveniently about. This type lasts a long time, and can be moved from place to place as space is available or required for other things.

For raising seedlings for planting out, boxes measuring 20 × 11 ins., with an inside depth of 3 ins., will be found of very suitable size. Another useful box is that obtainable from nearly all fishmongers, being the case in which dried fish is imported, and generally called a "kipper box."

1. Raising Vegetables under Glass to Maturity.—Amongst the vegetables that can be grown to the stage when they are fit for table entirely under glass, are Asparagus, Broad Beans and Peas, Climbing Beans, Globe and Long Beet, Carrots, Cauliflowers, Lettuce and other salads, and Potatoes.

Asparagus.—This delicious vegetable is one of the most easily forced. It is best brought forward in portable frames on mild hotbeds of leaves. Strong roots should be employed for this purpose, care being exercised that these are placed in position and covered as soon as possible after lifting, because, if they once become severely dry, the results will be anything but satisfactory. If a certain number of roots, according to requirements, are placed in the frames at intervals of a fortnight or three weeks, a regular supply of succulent heads can be relied upon throughout the early spring months, till the time comes round for cutting in the open, after which the frame can be utilised for many other crops. See also article on *Asparagus*.

Broad Beans and Peas.—For very early crops sow the seed of early and second early Peas and Broad Beans in the boxes containing a compost of 2 parts good fibrous loam, 1 part well-decayed leaf-mould, and 1 part finely sifted horse manure, the latter for preference being obtained from an old mushroom bed. The sowing should take

place very early in January and the seeds be raised in a gentle heat. They should be grown as sturdily as possible, and supported with small sticks as required. Give air freely, and avoid strong heat at all times. See also articles on *Beans* and *Peas*.

French and Climbing Beans.—For earliest supplies these will require to be grown entirely under glass. The seed should be sown at intervals during the depth of winter in the boxes, and liberal treatment once the seedlings are through will give heavy crops. See also article on *Beans*.

Beet, Carrots, and Turnips.—These may either be sown and matured in heated pits or portable frames on mild hotbeds. Care should be taken in preparing the compost that it contains no wireworm. Old potting soil, with some finely sifted leaf-mould, makes an admirable medium for these subjects. Exercise care in ventilating. Never allow the growth to become drawn, and strictly avoid overcrowding, especially with Beet and Turnips. Syringe twice daily with tepid water in fine weather. Sow at intervals from the beginning of January to the middle of March. See also articles on *Beetroot*, *Carrot*, and *Turnips*.

Cauliflowers.—Those sown in the autumn (September), and which have been pricked off into cold frames, are ideal for the work, but the strongest plants only should be used. They should be lifted and planted in the boxes, three plants being allotted to each when the size above given is used. Grow them on in a temperature of 50–55° F., and they can be had early for cutting. If the room they occupy is wanted for other crops, they may be hardened off, placed in a warm sheltered spot out of doors, and their growth finished in the open. Where room permits, they could be completely grown in the bed of a house, in a good depth of rich soil. In all cases they require liberal feeding. Two very good varieties for this method are *Magnum Bonum* and *Early Forcing*. See also article on *Cauliflower*.

Lettuce.—This can be raised and matured in frames, care being taken to avoid a strong heat. The compost should be similar to that recommended for Carrots, etc., and should be made very firm. Give air freely at all times. The quick maturing cabbage varieties are the best for this purpose. See also article on *Lettuce*.

Potatoes.—Very early Potatoes can be obtained in the boxes, or in 12-inch pots, small tubs, etc. The receptacle requires to be three-quarters filled with a compost composed for the larger part of well-decayed leaf-mould, more being added from time to time, by way of "earthing up," as the growth permits. They require an intermediate temperature, and the seed tubers should be greened and sprouted beforehand. Heated pits and frames may also be employed for this crop, removing a fairly good depth of the old bed and replacing it with the beforementioned compost. *Midlothian Early* and *May Queen* are two varieties that lend themselves admirably for this purpose. For general hints on Potato Cultivation, see article on *Potato*.

2. Growing under Glass and Maturing in the Open.—There are a number of vegetables which can, with great advantage, be raised to a stage under glass between the seedling and the mature plant, being hardened off and put out of doors in the boxes recommended,

or, if raised in frames, have the lights thereof removed, and thus grown on to table condition in the open air. By these means early supplies, coming in between the very early productions grown and matured in heat, and the much later maincrops grown in the open, are obtained. Primary amongst these are Broad Beans, Cauliflowers, Celery, Parsley, Peas, and Radishes.

Broad Beans.—Grown in the same way as the Peas, these can be plunged in their boxes three parts deep (as hereafter recommended for Peas), the growth being supported by stout string run between strong stakes placed at intervals along the rows formed by the boxes.

Cauliflowers. — One method of growing under glass was dealt with in the previous class. Another way is to plant them in frames on a mild hotbed, at distances of 2 ft. between the rows and about 16 ins. from plant to plant, the space between the rows being utilised for growing early Radishes. As the latter finish, Celery can be put in in their stead, and when the Cauliflowers mature and are cut, more Celery can take their place.

Celery.—This has just been dealt with, and it only remains to add that blanching can be effected by means of brown paper tied round the plants. See also article on *Celery*.

Parsley.—This is in request in nearly every household throughout the winter, and little trouble will be experienced in supplying it if late sowings are lifted from the open and placed in cold frames during September and October. Soot should be supplied plentifully to this vegetable. See also separate article.

Peas.—These have already been mentioned as to raising them under glass. If their room is required, then they can be hardened off thoroughly in cold frames and put outside at the foot of a south wall or building. Later on the boxes can be plunged in the ground about three parts deep, in rows, selecting a sheltered sunny position for them. Give plentiful supplies of water and liquid manure, and place the sticks necessary to support the growth *outside* the boxes. Grown this way very heavy crops can be obtained. Three good varieties for thus growing are *Quite Content*, *Duke of Albany*, and *Little Marvel*.

Radishes.—It is hardly necessary to devote special frames for this crop, as these can generally be intersown successfully between the various other crops from time to time. See also article on *Radish*.

3. The Raising of Seedling Vegetables for Planting out.—There is no question but that it pays in all ways to raise many vegetable seeds under glass, and some of these, such as Celery, Celeriac, Leeks, Lettuce, and Onions, are best raised in boxes in heat in such a place as an Early Vinery or a Peach House.

Celeriac requires the same treatment as Celery below.

Celery.—This requires a fairly light sandy compost, and the seeds should not be sown before 10th February, or the seedlings allowed to become dry at the root, otherwise the result will probably be a premature running to seed.

Leeks should be raised in the same way as hereafter recommended for Onions.

Lettuce can be sown at intervals and raised in the same way as suggested for Celery.

Onions.—By raising Onions in this way, one is able to plant out in a stage sufficiently large to practically escape the ravages of

the dreaded Onion Fly, the bulbs ripen earlier, are better for keeping, and can consequently be cleared sooner, thus freeing the ground for other crops. The seed should be sown thinly in a compost such as recommended for Peas, to which is added sufficient sand to keep it thoroughly open. The mixture should be fairly fine, say able to pass through a ¼-inch sieve.

When the seedlings are about 1½ ins. high prick them out into other boxes at about 3 ins. apart each way in slightly coarser compost, to which add a small quantity of bonemeal. In all stages keep close to the glass to afford plenty of air and light. About the third week in March start to harden off, and plant out about the middle of April. A temperature of about 55–60° F. is best for raising in, and the soil should be kept moist. See also article on *Onion*.

In all cases seedling vegetables raised in heat must be well hardened off before they are planted out. See article on *Hardening Off*.

Ed. B.

[For Seakale, etc., see our article on *Vegetables: Blanching and Forcing*.—Editor.]

VEGETABLES: Varieties of.—These are given at the end of each article on a vegetable. For selections for Light and Heavy Soils, however, see *Vegetables: General Considerations*.

VEGETABLES: Weights of Bushels of.—See *Weights and Measures*.

VEITCH'S SILVER FIR (*Abies Veitchii*).—See *Trees*.

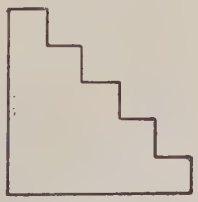
VEITCH'S VIRGINIA CREEPER (*Vitis inconstans*).—See *Climbing and Trailing Plants*.

VENETIAN SUMACH (*Rhus Cotinus*). See *Shrubs*.

VENTILATING FERN HOUSES.—See *Ferns and Fern Gardening*.

VENTILATION.

This is of importance for two principal reasons, namely, for giving air to the plants,—for plants as a general rule need nearly as much fresh air as human beings,—and secondly, as a means of drying up surplus moisture, and so preventing that dreaded malady "damping off" from setting in.



Ventilation is done in many very careless ways. For instance, one often sees the bottom ventilators open during the bitterest weeks of the year, and the cold air, also snow as well, blowing in.

As ventilation is of such great importance, greenhouse builders should contrive an arrangement by which the cold air can first be warmed on cold days by passing over or near the heating apparatus. Then the lower ventilators will not need to be open.

The top ventilators of greenhouses should be opened more often and more freely than they are. Much less damage will be done this way than by allowing bitter winds to blow right on to the plants through the bottom ventilators.

With span-roofed houses, so long as there are ventilators at both sides and both ends, air can be admitted on the opposite side from that on to which the wind is blowing. That is a small point not often thought of, but how important it is!

A word must be said about ventilating frames. This should be done on all fine days, for the more air the plants get, the hardier and stronger they will be. Ideal supports for the framelights can be made by cutting pieces of 2-inch thick wood into "steps," as is shown

Frame Ventilator.

in the illustration. When only a little air is needed, support the light on the lowest step; when more is wanted, rest it on other steps. Tilt the light so that the wind passes over it, and not under it, on bitter days. See also article on *Hardening Off*. E.

VENTILATION OF GRAPEHOUSES or VINERIES.—See *Vines*.

VENUS'S LOOKING-GLASS (*Specularia*. Nat. Ord. Campanulaceæ). — This plant, sometimes known as the Corn Violet, is one of a group of very charming, hardy, summer flowering annuals, named the Specularias, all of which are eminently suitable for the decoration of spaces in the rock garden. Autumn sowing where the plants are to flower suits them best, but whether sown in the spring or the autumn they should certainly be thinned out to about 6 ins. apart each way. The following are the best species :—

Specularia falcata.—A blue summer blooming annual, about 1 ft. high.

S. hybrida.—Pale blue or lilac, blooming from June onwards. About 6–12 ins. high.

S. pentagonia.—Deep blue, blooming from July onwards, and averaging 1 ft. high.

S. perfoliata.—A purple-blue species, flowering about midsummer, and growing about 1 ft. high.

S. Speculum (Syns. *S. arvensis, hirsuta, stricta,* and *vulgaris*).—This is the well-known Venus's Looking-Glass so often grown. It is almost needless to say that it bears white or purple flowers through the summer, and averages 12 ins. in height.

VENUS'S NAVELWORT.—A name applied to *Omphalodes linifolia*.

VERATRUM (False Hellebore. Nat. Ord. Liliaceæ).—This is a genus of poisonous plants all of which are hardy herbaceous perennials quite undesirable in gardens where children play among and pluck the flowers unchecked, but they are none the less beautiful. From the root of *V. album* the well-known nasal irritant *White Hellebore Powder* is obtained. This genus must not be confused with the true Hellebore described in our article on *Helleborus*.

Culture.—The cultural requirements of Veratrums are of the simplest, though they certainly appreciate a rich deeply worked soil, the richer the better; otherwise ordinary border culture which is often so haphazard will prove quite as successful in their case as with any other genus of plants. They may be easily propagated by seeds sown at the usual time, also by root division in the autumn or spring (but gloves should be worn for this operation). Planting may be successfully carried out from mid-March onwards.

What to Grow.—We recommend the following :—

V. album (White Hellebore).—This, as its name implies, bears white flowers. It blooms from July onwards, and averages 4–5 ft. in height.

V. lobelianum is a synonym of the above.

V. nigrum.—This bears very dark purple, and at times almost black flowers from June onwards, and grows 2–3 ft. in height.

V. viride.—This is popularly known as Indian Poke. It is the least desirable of all, bearing greenish flowers in July, and averaging 4 ft. in height.

VERBASCUM.—See *Mullein*, and under Mullein in *Medicinal Herbs*.

VERBENA (Nat. Ord. Verbenaceæ). Florists' section, greenhouse and half-hardy herbaceous plants, 1–2 ft. high, succeeding in light, rich, sandy loam, and propagated by seed or cuttings.

Culture.—Seed sown in early spring in the greenhouse will produce plants for summer flowering, either transplanted out of doors when safe against frost, or potted up for indoor decoration. Particular varieties or colours are perpetuated by cuttings from the young growths, and rooted in light, sandy soil.

Uses.—Verbenas are more used for border work nowadays than grown under glass as florists' flowers as they used largely to be. Their brilliant colours and long season of bloom, which lasts throughout summer, make them valuable for both beds and herbaceous borders.

Varieties.—With the exception of the well-known variety, *Miss Willmott*, few named Verbenas are now sold. As, however, choice strains of seed are offered in separate colours, and these come practically true, this fact is hardly to be regretted.—J. L. G.

VERBENA: Lemon Scented.—See *Aloysia*.

VERBENA SPECIES.

Apart from the florists' section already described, there are a few useful species of Verbena which are quite hardy and well worth growing.

Biennial Border Species.—These require the usual treatment given to hardy biennials, being sown one year for blooming the next. We recommend the following:—

Verbena Aubletia (Syn. *V. Oblaetia*).—This is the well-known Rose Vervain bearing purple flowers from July to August, and growing 9–18 ins. high.

Perennial Border Species.—These are useful hardy herbaceous perennials quite easily grown in light, rich soil, and useful also in the shrub border, or in marginal borders to the wild garden. The taller forms need to be efficiently staked, but otherwise the plants look after themselves. They may be propagated in the usual way by root division in March, which is the best planting period. We recommend the following:—

Verbena biserrata.—Syn. *V. polystachya*, which see.

V. caroliniensis.—Syn. *V. polystachya*, which see.

V. officinalis (Common Vervain).—This is probably the best known species. It bears purple flowers from June to August, and grows 1–2 ft. in height.

V. polystachya (Syns. *V. biserrata* and *V. caroliniensis*).—This is quite the best species of all with its brilliant red flowers from July to August, on plants 3–5 ft. in height.

VERDIGRIS.—See Copper Acetate in *Copper and Cuprum Compounds*.

VERDIGRIS FUNGUS.—See Harmful Fungi in *Fungi: Edible and Harmful*.

VERNONIA (Iron Weed. Nat. Ord. Compositæ).—This is a pretty genus of plants which should be more grown, as up to the present time it has been much neglected.

Greenhouse Species.—Only one species responds to cool greenhouse treatment, namely, *Vernonia sericea* (Syn. *V. acutifolia*). This bears purplish flowers in December, and averages 5 ft. in height. A number of Stove Species are excluded in accordance with our note on *Stove Plants*.

Perennial Border Species.—These are hardy herbaceous plants unsuitable for the front of borders as a rule since they grow somewhat tall. They may be used for the back rows, however, and are also useful for the sunnier front rows of the wild

garden borders, where they form bold subjects. Ordinary light loam suits them admirably, and some will succeed well in town gardens. Propagation by seeds in the summer and root division in the usual manner in the autumn or spring is a simple matter, and successful results may confidently be anticipated by planting in March. We recommend the two following :—

Vernonia altissima (Syn. *V. angustifolia scaberrima*). — This bears purple flowers in October, and averages 10–11 ft. in height.

V. novaeboracensis (Syn. *V. praealta*). — This also bears purple flowers, but blooms in July and August. Its height averages 4–8 ft.

VERONICA (Speedwell. Nat. Ord. Scrophulariaceæ).—About a hundred species of Veronica are grown at Kew, but obviously to describe anything like this number here would be quite beyond the scope of the present work. There are hardy annual, greenhouse perennial, shrubby, as well as hardy perennial or herbaceous border species and rock garden species to choose from, but with the two former we need not trouble here, although *Veronica glauca*, a blue annual, is useful as an edging plant. The best evergreen shrubby Veronicas are included in our list of shrubs (see *Shrubs*), so these also are not described or included in the present article. Any ordinary garden soil (provided it is moderately gritty) seems to suit the plants, which are mostly very easy to grow. They are best propagated by division of the roots in the spring, which is also the best time to plant, though in warm districts November planting gives satisfactory results.

Perennial Border Species. — We describe a few of the best below, and may point out that most of the rock garden species are suitable also for the perennial border if used as edgings :—

Veronica Allionii.—This blue sort flowers in May, and attains a height of 6 ins.

V. alpina.—This is a blue sort suitable for edging purposes and flowering in May. Its height is 4 ins.

V. austriaca (Syn. *V. multifida*).—This is a useful blue July flowering species growing about 12 ins. high.

V. azurea.—This attractive blue sort flowers in May, and grows about 1 yd. high.

V. caucasica.—A very useful sort bearing light red flowers from June onwards. Its height is about 12 ins.

V. Chamaedrys (Germander Speedwell).—This sort bears bright blue flowers for a lengthy period in the summer. It grows about 6 ins. high.

V. gentianoides.—This bears pretty violet blooms from June onwards, and grows about 2 ft. high.

V. hybrida. — There are two varieties of this, namely, *newryensis* and *tobascorrensis*. Both bear blue flowers and bloom from June onwards, averaging about 12 ins. high.

V. incisa. — This bears blue blooms from July onwards, and averages 2 ft. high.

V. longifolia.—This bears its attractive blue flowers from June to August, and averages 3 ft. in height. The variety *subsessilis* is now recognised as a distinct species, and is thus described separately.

V. montana.—This attractive blue sort flowers in July, and grows about 6 ins. high.

V. multifida.—Syn. *V. austriaca*, which see.

V. officinalis (Fluellen, etc.).—This, used for medicinal purposes, is not largely grown. It is a blue

June flowered plant averaging about 4 ins. in height.

V. paniculata.—Syn. *V. spuria,* which see.

V. pectinata.—This is quite a useful sort. It bears blue flowers from May onwards, and averages about 12 ins. in height.

V. prostrata.—This indispensable sort is now named *V. Teucrium dubia,* and is described under the rock garden species further on.

V. repens.—This is a useful white-flowered sort blooming in August and September. It height is about 3 ins.

V. rupestris.—This is a synonym of *V. prostrata* and *V. Teucrium dubia.* It is described under the latter name in the rock garden species below.

V. spicata.—This, described under rock garden species, is exceptionally useful as well for the front of perennial borders.

V. spuria (Syn. *V. paniculata*).—This useful blue sort blooms in June, and averages 18 ins. in height.

V. subsessilis (Syn. *V. longifolia subsessilis*). — This undoubtedly popular blue-flowered sort blooms from July through August and sometimes into September. Its height is 2–3 ft.

V. Teucrium dubia (Syns. *V. prostrata* and *V. rupestris*).—This sort, indispensable for edging, is described under the rock garden species below.

Rock Garden Species. — Many species of Veronica are most suitable for the rock garden on account of their dwarf compact habit. Six of the best are described below, which will thrive in any open position in sandy well-drained soil, and are propagated by division of the roots in autumn or spring.

Veronica canescens.—This is a creeping plant forming close carpet-like mats. Leaves minute hoary. Flowers pale lilac. Site, half-shade. Soil gritty, moist loam. Flowering Period, June to August. Height, 1 in.

V. filifolia.—This forms tufts of short stems clothed with finely divided leaves. Flowers light blue. Site sunny. Soil light loam. Flowering Period, May to July. Height, 9 ins.

V. incana.—This dwarf species has silvery-white foliage. Flowers deep blue in spikes. Site sunny. Soil gritty loam. Flowering Period, June to August. Height, 9 ins.

V. saxatilis (Rock Speedwell).—This forms mats of slender woody stems, with evergreen foliage. Flowers rich blue, with crimson eye. Site sunny. Soil gritty. Flowering Period, June to September. Height, 3 ins.

V. spicata.—This is a most useful dwarf evergreen species splendid alike in the herbaceous border and rock garden. Flowers clear blue in dense spikes. Site sunny. Soil gritty loam. Flowering Period, July to September. Height, 9 ins.

V. spicata alba bears white flowers, while the variety *rosea* has pretty rose-pink flowers.

V. Teucrium dubia (Syns. *V. prostrata* and *V. rupestris*).—This is a low-growing evergreen plant. Flowers blue in long spikes. Site sunny. Soil sandy loam. Flowering Period, June to September. Height, 3 ins.

VERONICA MILDEW.—See *Diseases of Rock Plants.*

VERVAIN.—A popular name for *Verbena,* which see.

VERVAIN MALLOW (*Malva Alcea*).—See *Malva.*

VERVAIN SAGE (*Salvia Verbenaca*). See *Salvia.*

VESPA.—See under Wasps in *Insect Pests.*

VESPIDÆ.—See Wasps in *Insect Pests.*

VETCH.—See *VICIA*.

VIBURNUM.—For the best species see *SHRUBS*.

VICIA (VETCH and TARE. Nat. Ord. Leguminosæ).—This is a large genus of hardy plants of no great value to gardeners, though some such as *V. Faba*, the BROAD BEAN, are grown as vegetables (see article on *BEANS*), while others are grown as green manuring crops. The most important species after the Broad Bean are *V. bithynica*, the PURPLE VETCH; *V. Cracca*, the TUFTED VETCH; *V. Faba equina*, the HORSE BEAN; *V. hirsuta*, the COMMON TARE; *V. lathyroides*, the STRANGLE TARE; *V. Orobus*, the BITTER VETCH; *V. sativa*, the COMMON VETCH; *V. sepium*, the BUSH VETCH; and *V. sylvatica*, the WOOD VETCH. Some of these may be grown in the wild garden, but if space is precious they may be dispensed with.

VILLA GARDENING.

If the Englishman's house is his castle, his villa garden may be said to be his park, home grounds, and garden combined. True, most of our large towns now boast one or more public parks, where citizens may expand their lungs and rest their eyes on Nature's greenery; but the ordinary man, when laying out his villa garden, still cherishes a patch of green by way of a lawn, even if it be no bigger than his front-room carpet. There is much to be said for this grass plot, for where there is a family of young children it serves as a playground in the summer and a place where meals may be eaten out of doors—a virtuous practice which should certainly be encouraged.

Speaking in general terms, the usual villa garden in an average city suburb is in two parts: a small, square, front garden of varying size, and a narrow strip at the back, in length from 30 to 200 ft., or even more. Dealing first with the front garden, if this is an ample square of, say, 20–30 ft., there will be all sorts of possibilities for a successful planting of shrubs and flowering trees. Care must be taken to avoid anything which will grow big and block a full volume of light into the house. I have in mind, as I write, a residential road in a modern suburb in North London, where all the front gardens are protected from the public footway by a low wall, surmounted by a privet hedge. This hedge is supported or guarded at each end by a pollarded lime tree of considerable size. The general impression is that of a row of giant policemen on duty awaiting a royal procession to pass along. It is formal gardening carried to the extreme of ugliness. If trees are desired to add beauty to the road, choose one of the flowering varieties such as the Almond, Double Peach, the copper-leaved *Prunus Pissardi*, the Rowan (glorious in the autumn), or a graceful Silver Birch. Laburnums and Thorns are beautiful when in flower, but not attractive after.

As regards the border hedge, if such is desired to shield the garden from the road, there are distinct advantages in the golden privet and golden yew. Both can be trimmed, and they brighten up the landscape in winter. Variegated holly is also useful. By the sea the golden Euonymus does very well for the same purpose. In the Garden City, Letchworth, dividing hedges are often found of Dorothy Perkins roses, pretty whilst in flower, but at all times unruly subjects. Among other shrubs which do well in the ordinary front garden, the following may be mentioned: Aucuba, Berberis,

Choisya, Cistus, Cotoneaster, Daphne, Garrya, Juniper, Ribes, *Veronica Traversii*, and Viburnum. Care should be taken to avoid crowding; also subjects which may tear a hole in your visitor's new summer frock when she makes a call upon you, should not be planted.

The front of the house will usually lend itself to some adornment either by the judicious use of climbing roses such as *Gloire de Dijon* or *William Allen Richardson*, or by such useful climbing shrubs as Forsythia and *Pyrus japonica* (early flowering), *Clematis montana* (May flowering), Pyracantha (crimson autumn berries), Yellow Jasmine (winter flowering). There are many others equally suitable.

The rest of the front garden may be devoted to a border by the house for early bulbs and wallflowers, with a late planting of annuals, or, if something more formal is desired, bright geraniums or begonias.

Turning now to the strip of garden at the back of the house, our thoughts naturally go in the first instance to food production. Before the War I would have hesitated to advise the introduction of any food crops other than such subjects as peas, tomatoes, scarlet runners, and marrows in any but the larger villa gardens. Even now, though so great an interest is taken in vegetable growing by nearly everyone, I will not recommend the planting of cabbages in the villa garden unless you are an entomologist, with a hobby for rearing white butterflies, ichneumon flies, and cabbage moths.

In arranging the position of the vegetables in the villa garden, if possible keep them well away from the house. They will then be much cleaner and healthier, and you will avoid large expanses of brown earth right underneath your windows. On the other hand, the patch of lawn—if you can afford it—may be as near the house as possible, so long as it gets plenty of sun; otherwise it will suffer from moss, and wear damp and sodden.

Planning a Villa Garden.— In planning out my own garden, a narrow plot measuring 24 ft. wide by about 120 ft. long, I aimed first of all at veiling the ugly timber of the boundary fences with greenery, and, secondly, to give the impression of greater size to the garden, by curving paths, the right placing of rose arches and rose screens, the allocation of a section for a miniature rock garden, and another for a perennial border. The fences have been veiled with currant and gooseberry trees, with here and there a Pyrus, Forsythia, Ceanothus, and Jasmine, to give colour in their flowering periods. On the north fence, facing south, a rose screen of *Dorothy Perkins*, *Crimson Rambler*, *Tea Rambler*, and *William Allen Richardson* shields the lawn from observation from the next garden. This gives a little more privacy than would otherwise be the case. An escarpment of rockwork, with shrubs and alpines, catches the eye from the dining-room window, and at the far end of the garden a rather larger piece is devoted to more rock plants and ferns. The perennial border leads from the lawn to the bottom of the garden, with a mixed bed of roses, pinks, etc., on the left hand side of the path. The principal rose arch, a double structure with *Hiawatha*, *Crimson Rambler*, *Gloire de Dijon*, and *Gruss an Teplitz* meeting in gay company overhead, divides the lawn section from the other part of the garden. In this small domain I find it possible to grow over two hundred varieties and species of flowering plants. That there is

crowding at times, I do not deny, especially among the rock plants, but the number and variety add to the joys of the garden, for there is always the expectation of discovering some new favourite in flower. In a small garden, if the aim is variety, the strong-growing plants must be excluded or vigorously cut back. In the herbaceous border, for instance, Paeonies and Oriental Poppies, the larger Delphiniums, Sunflowers, and Michaelmas Daisies should be avoided. It pays better to devote the space to Delphiniums, such as *Belladonna*, to long-spurred Aquilegias, Pyrethrums, Lilies, the less common Irises and bulbs, Lupines, Canterbury Bells, Œnotheras, Salvias, especially *S. patens*, Doronicums, Phloxes, the fairy-flowered Michaelmas Daisies, Heleniums, Anchusas, etc. Antirrhinums and Pentstemons will work into gaps left by the spring bulbs for the summer months. If you can spare a small bed for Crown Imperials and Tritomas, you will be rewarded with a most interesting lily subject in the spring and a grand bit of colour in the autumn. The perennial border may be backed by pillar roses or a rose trained along a chain. *American Pillar* is a good subject for the latter purpose.

For a sunny border there is nothing more delightful than grey-foliaged plants with blue or mauve flowers, sweetly scented, of course. We find Thyme, Rosemary, Lavender, Catmint, Cotton Lavender, and *Salvia patens*, with Ceanothus on the fence, ideal subjects for such a position.

If there be room for fruit trees, a Victoria and Golden Drop Plum, a Cherry, a Siberian Crab as standards, and apples or plums as espaliers or cordons, will all alike add beauty and fruitfulness to the garden.

The Villa Rock Garden.—A word, in conclusion, about the rock garden. If the garden has a sunny aspect, speculate in sun-loving rock plants, and give them plenty of room, especially in the matter of root run. A few include Saxifrages (encrusted varieties), Sedums, Sempervivums, Campanulas, Gentians, Lithospermums, Arenarias, Aubrietias, and Rock Roses. Thus it will be seen that there is a wide selection of sun-loving plants to choose from.

For a shady garden it is better to rely upon Anemones, Primulas, heaths, Violas, mossy and fleshy-leaved Saxifrages, Ramondias, and the rarer species of ferns. After some experience, I have come to the conclusion that it is not worth while devoting time and money to the high alpines in a villa garden. Even in the moraine, they only live for a summer or two, and then often in a semi-consumptive state that worries you every time you look at them. Among the rock plants of greatest value for the villa garden I would name Anemones, Campanulas, Primulas—an extraordinarily interesting family—and Saxifrages. There are enough good things in these four families to give interest all the year through.

S. G.

[Our contributor, who has had a long experience as a villa gardener, ably shows in this article the immense possibilities there are even when the area is excessively small. Those who think their small villa gardens are no use for producing food, fruit, or flowers, should take courage, and try some of the above. See also our article on *Town and City Gardening*.—Editor.]

VILLARSIA.—Now included in the genus *Limnanthemum*.

VINE MILDEW.—See *DISEASES OF PLANTS*.

VINE WEEVIL.—See under OTIORHYNCHUS WEEVILS in *INSECT PESTS*.

VINES (*Vitis vinifera*. Nat. Ord. Ampelidaceæ).—Vines are a very graceful and accommodating fruit, and will grow in almost any kind of soil or structure, where light and air can be given them. Span-roofed, three-quarter-span, and lean-to houses are the general style of structure found most suitable. The width of the house should not be less than 15 ft.; ventilation, heating, and other details may safely be left to the builders. Wires should be 10–12 ins. apart and not less than 20 ins. from the glass; by this means the vine leaves are less apt to get scorched or chilled. Let us suppose the house to be constructed on the above lines in a nice light, open position, away from the shade of large trees, sufficiently high to admit of natural or easy drainage. (Low situations with wet, cold subsoils, we may remark, should be avoided, or precautions taken to raise the borders above the ground line. A well-drained border is much drier and warmer than one too low or water-logged.) Then the depth of the border is our next consideration. This may vary from 2 ft. to 2 ft. 6 ins.; there should not be less than 12 ins. of good drainage. It is, therefore, necessary that a depth of 3 ft. 6 ins. to 4 ft. below the front sill be left to admit of a layer of concrete,—the concrete is not always necessary, — with broken bricks and lime rubble on top for the soil to rest upon.

Making the Border.—Success or failure often depends upon the way the border is made and drained; the concrete, if necessary, should have a gentle slope outwards towards the drains which carry the water away. Rough, broken brick-bats should be placed over the concrete, and no pains should be spared in carefully levelling the top layers with fine rubble, otherwise in course of time the soil will work into the drainage and the roots will follow, with the inevitable result of shanking and other evils. Although the vine is found flourishing in nearly every kind of soil, and new turf cannot always be obtained near large towns, still fresh virgin loam is almost a necessity to ensure a lasting success. This may be obtained from roadsides or a stiff pasture, and corrected with other materials, according to its texture. A good compost consists of two-thirds good, fresh, fibrous loam; the remaining third should consist of lime rubble, charcoal, and burnt earth, with 10–12 per cent. of half-inch bones and bonemeal, to ensure a vigorous, short-jointed growth. No animal manure should be used, but a little soot is good if wireworms are present in the turf. Chop up the soil roughly, mix well, throw the compost into a heap, and keep under cover until required. Not more than 3–3½ ft. of the border should be made the first season; place a layer of turf, or even two, grass-side downwards, to the required width, using a similar turf to build up the retaining wall,

filling in the prepared compost, which can hardly be made too firm. The making up of small borders is now generally done inside, as by adding to the borders every alternate year the vines can be kept in vigorous health for many years. Few good gardeners now make outside borders, but rely on the inside border only. The general practice years ago was to plant in spring ripened canes of the previous year's growth, and where this system is still adopted, shake away the loose soil from the ball, disentangle the roots, spread them out carefully, and plant in March. The planting of young growing vines from April to July, struck from eyes the same spring, is by far the better method, only in this case the ball must not be broken at all. Plant firmly, using fresh, warm soil, water with lukewarm water, shade slightly, and keep the vinery rather close for a few days until fresh growth has commenced. Vines on the single-rod system should be planted 3½–4 ft. apart, and those planted on the two-rod system in proportion. As soon as the former have made growth half an inch long, remove the growth by degrees down to the front sash, leaving one on each side with a leader; pinch the side-shoots once when they are 2 ft. long, and the leader, when it has made about 5 ft. of growth. Spring struck vines will cover the whole roof the same year. Encourage all lateral growth with plenty of good leaves, and so ensure plenty of good roots to build up next year's canes. The temperature for well-ripened vines of the previous year's growth should range about 50–53° F. by night, with 10° to 15° higher by day. The house must be kept moist by sprinkling the paths, etc., with water two or three times daily. Gradually increase the temperature to 60° F. by night as the vines increase in growth. Give top ventilation only as soon as a rising thermometer reaches 70° F., increasing as the temperature rises. Damp the houses, and close early in the afternoon, to dispense with artificial heat as much as possible. Caution is necessary never to damp the house when the temperature is low, as a low, damp temperature produces mildew. Spring struck vines require a close, moist atmosphere, with a night temperature of about 65–70° F., with 10° to 15° higher by day. As the season advances, front ventilators must be opened, and the amount of air increased as the wood begins to ripen, until both wood and roots are thoroughly matured, which will be about the end of September. Taking the young, growing vines first, these should be cut down to the ground, leaving about two buds; by this means a stronger growth will be secured, which must be carefully staked, tied, and guarded against injury until established.

Second Year's Treatment.—Prune the young vines early in January, leaving the leader about 3 ft. long, cutting the side-shoots close to the main rod, leaving two leaders on the two-rod system. Wash the house thoroughly, also the vine, with a strong insecticide, taking care never to damage the buds, and scrub the walls with hot lime-wash. Examine the border, and if many new roots have extended freely outside the border, remove about 3–4 ins. off the retaining wall with a sharp edging iron, adding about 18 ins. of new border as before. By thus cutting back the roots, numerous fibrous roots will result, which is a most important item. A little bonemeal or vine manure may be used with the surface dressing, but when the borders are

made in a proper manner, stimulants must be used with caution, as much harm is often done in the early stages by the too liberal use of artificial manures. Close the house at the beginning of March, always avoiding high temperatures—50° by night, with the usual rise during the day, is quite high enough. Increase the temperatures as the season advances, and supply moisture as previously recommended. The vines may be lightly syringed once or twice a day until the buds burst; the syringe should then not again be used on the vines except in cases of emergency. There is very little danger of the leading shoot running away from the others. When time is given the vines break in a natural manner, without having recourse to a high temperature. Disbudding of young vines is most important; the spurs should not be less than 18 ins. apart on either side, and all except the two strongest should be rubbed off when about ½ in. long, selecting the best placed afterwards. Pinch the leading shoot after it has made about 5 ft. of growth, afterwards allowing the leader to extend its full length, pinching all tendrils as they appear. If the vines have made good progress, a bunch or possibly two may be left on each vine; in this case the side-shoots should be pinched two leaves beyond the bunch. Sub-laterals will start, which should in turn be pinched back to one leaf. Muscats are all the better by being allowed a little more freedom of growth. Do not be in a hurry to tie down the shoots; time and patience is required, since strong young shoots are easily broken. Thin them down by degrees, and, later on, they may be tied into any position without injury.

Pot Vines.—These are the best for very early forcing; by their use permanent vines may be allowed a longer season of rest. Space will not allow us to go into details of their culture; sufficient to say, good loam, rich top-dressings, with liberal supplies of manure and plenty of water, are necessary to bring them to maturity. A slight bottom heat in the early stages is an advantage, but not a necessity. A well-grown vine in a 12-inch pot will mature six or eight bunches of grapes; the right temperatures should not exceed those recommended for permanent vines. Black Hamburgh, Foster's Seedling, Madresfield Court, and Buckland Sweetwater are the best varieties for this purpose, and six months should be allowed from starting to ripening of the fruit.

Permanent Vines.—These should be started in time to have the fruit ripe by the end of September. It is impossible to go into every detail of their cultivation, as no hard and fast rule can be laid down to suit every case; but constant and careful daily supervision is necessary with the house and vines. Thoroughly cleanse before starting after being pruned. Prune the vines to two buds, leaving the leader about 2 ft. long each season, until it reaches the top of the house. After the shoots have made about ½ in. of growth, disbud the vines carefully, always selecting the best placed shoot, which generally shows the best bunch. Stop the shoots one or two leaves beyond the bunch, and tie down the shoots gradually. Stop sub-laterals as they appear at the first leaf. Gradually raise the temperature after the bunches are visible up to 65° F., for free-setting varieties. Muscats require a slightly higher temperature when in flower. It has, however, been proved that all grapes will set and mature their fruit in a much lower

temperature than has generally been considered necessary. We have always been great believers in time and low temperature in the growing of all kinds of indoor fruits, especially in the early stages, as one of the best preventions against red spider, mildew, and other evils. Supply moisture by damping all available spaces to keep the vines healthy according to the outside atmosphere. Reduce the moisture considerably during the time the vines are in flower, and go over the bunches of Muscats and other shy-setting varieties in the middle of the day, with foreign pollen on the brush taken from Hamburgh or other free-setting varieties, tapping the rods of all varieties.

Thinning.—This requires experience and knowledge of the different varieties. You can only thin and regulate the berries in the first place, however; nearly all inside berries should be moved, those left will then place themselves in position as they swell. First remove all surplus bunches, leaving twelve or fourteen of the best, reducing them again at the second thinning. If large exhibition bunches are needed, a healthy rod will carry ten to fourteen bunches. The second thinning, which should be done a week later, is more important, as the size and shape of the bunch has to be considered. Remove all small and weak-necked berries, and tie up the shoulders according to the size of the bunch and variety. Large bunches need to be looked over even a third time.

Ventilation.—This, with watering, may be considered the most important operation connected with growing grapes. It is not only to regulate the temperatures, but to admit fresh air, which helps to keep the foliage clean and healthy. We prefer to close early, with a gradually increasing warmth in the pipes, keeping one eye on the weather, and the other on the boiler. With few exceptions in very cold weather a little night air should always be given, and especially is this necessary during the stoning period of Lady Downes' and Muscats, to prevent scalding, which is caused by imperfect ventilation or too high and moist temperature. Increase the ventilation early in the morning before the temperature rises too high. Reduce the temperature slightly, with a freer circulation of air night and day, while the grapes are colouring, and always keep a gentle warmth in the pipes for the above two varieties.

Watering.—Only from experience can it be realised the quantity of water well-drained borders require, and more young vines are injured from this neglect than from any other cause. A border tester should be used for inside borders; the old plan of withholding water just before the grapes are ripe is wrong. Heavily cropped vines where the finish is doubtful, should be given a good watering, if necessary using a quick stimulant. This, with careful ventilation day and night, and a gentle warmth in the pipes, will generally turn the scales in your favour.

Varieties:—*Black Hamburgh.*—The best early Grape of easy cultivation, medium bunches, covered with fine bloom, suitable for cold houses.

Foster's Seedling.—An early white sweetwater Grape of easy cultivation, an excellent companion to *Black Hamburgh* for early forcing.

Gros Colman.—A very large black Grape of second-rate flavour, handsome, and of good keeping qualities.

Lady Downes' Seedling.—An excellent late-keeping Grape of fine quality, that will keep in bottles in good condition till June.

Madresfield Court.—A fine purplish-black Grape of strong Muscat flavour, handsome and excellent.

Muscat of Alexandria.—Bunches large, golden-yellow when well ripened, excellent in every way.

There are many other varieties of Grapes worthy of cultivation in large establishments. Some of these are—

BLACK:—Alnwick Seedling, Appley Towers, Black Alicante, Gros Guillaume, Gros Maroc, Muscat Hamburgh.

WHITE:—Buckland Sweetwater, Canon Hall Muscat, Chasselas Napoleon, Duke of Buccleuch, Mrs. Pearson, and White Frontignan.

F. J.

VINES: TOP-DRESSING FOR.—See *TOP-DRESSING.*

VIOLA (Nat. Ord. Violaceæ).

The modern Viola is sometimes termed the Tufted Pansy. It is one of the very best bedding and border plants in cultivation, and the finer large-flowered varieties are largely grown by amateurs as "Show" flowers. It differs from the Pansy proper in being more of a perennial in its character, in addition to which it produces a wider range of clear, clean, self-coloured flowers. This perennial character is derived from the parentage on one side. The early raisers who worked on it fifty to sixty years ago used *Viola lutea* and *Viola cornuta* as the female parent and crossed with pollen of the bedding pansies of the day. Both James Grieve and Dr. Stuart put on record these early parentages. The large-flowered pansy is derived chiefly, if not exclusively, from *Viola tricolor*, an annual species.

Culture.—Violas grow well in any good garden soil, but amply repay a little special attention. Having grown them for over thirty years, the writer's advice is to prepare the beds thoroughly in the autumn and plant early in March. In some districts where the soil is free and well-drained autumn planting can be carried out with success, especially with the hardier bedding varieties. In a very free or sandy soil, such as exists in the Royal Horticultural Society's gardens in Surrey, beds for Violas want special preparation to get first-class results. Some 4 ins. of the top soil should be temporarily removed from the beds, and a layer 2–3 ins. thick of old cow dung spread on the surface and forked in, after which the temporarily removed soil may be replaced. The roots soon go down and get hold of the manure, after which they grow amazingly. So much for a very free soil. On a medium or heavy soil the manure need only be thoroughly dug into the top spit. The plants should be set out in lines 12 ins. apart, allowing 8 ins. between the plants.

Propagation.—Violas are the easiest things to propagate. A cold frame is best, but a shaded border does all right for the bedding varieties. In August or September young growths should be pulled out of the centres of the old plants,—if a little piece of root is attached so much the better; if not, cut the growth cleanly across below the lowest joint. Dibble in sandy soil a few inches apart, and make very firm, sprinkling with water immediately, and later as required. In about three weeks they will have rooted. If in a frame with a sash over them, shade the glass with a little whitewash inside, and leave a little air on continuously.

Seed is easily saved from the best flowers if desired, or it can be purchased from any good seedsman. Sow in February in frame or cool greenhouse for late summer flowering. Sow in May or June for spring

and early summer blooms. It is best to sow in a box of fine soil and cover the box with a sheet of glass till germination takes place. When the young plants have got three or four good leaves, transplant into larger boxes or a cold frame or even out of doors. If carefully looked after with water, and a little shade if necessary, they will grow rapidly. Transplant with all soil possible adhering to their roots when nice little bushes, and great will be the interest when they come into flower. If the flowering period is to extend, as is quite possible, from April to November, the dead flower heads must be regularly clipped off.

Varieties.—At first Violas were rayed or marked with lines on the lower and side petals, but now the pure self-coloured varieties are preferred, and the following lists embrace many of the choicest:—

FOR BEDDING: — *Crimson.*—Crimson Bedder.
Crimson Purple.—Councillor Waters.
Indigo Blue.—Archibald Grant, W. H. Woodgate (light blue).
Mauve. — Dunbryan (white centre), Fred Williams (dark), Maggie Mott (soft), Mauve Radiance (radiant colour).
Purple.—Jubilee (dark).
Rose.—William Niel (pale).
White.—Purity, White Swan.
White and Purple.—Mrs Chichester.
Yellow.—Grievii (pale), Kingcup (rayless).
FOR EXHIBITION: — *Cream.* — Jessie Harrison (tinted lilac), Mary Burnie (edged heliotrope), Willie Farmer (edged blue).
Purple.—Coronation (lighter edging).
Rose. — Moseley Wonder (marbled white), Mrs Robertson (large pink).
White.—Agnes Kay (edged heliotrope), Mrs C. Milligan, Mrs Quinton McFadyen (French white with heliotrope), Mrs W. R. Milligan.
Yellow.—Baron Newlands (edged heliotrope), Lord Kitchener (self), Moseley Perfection (deep).

The following twelve varieties of Exhibition Violas were oftenest shown in the winning stands at the National Pansy and Viola Show at Birmingham in 1918: David L. George, Kathleen Coates, Moseley Perfection, Moseley Wonder, Mrs J. Fisher, Mrs J. Smith, Mrs J. Terris, Mrs Mason, Mrs W. Barr, Mrs W. R. Milligan, Oxhill Purple, Sir Edward Grey.

Violettas.—This is a charming race of miniature flowered varieties, mostly very sweetly scented. The first of the race was "Violetta" (white with yellow centre), raised by the late Dr Stuart of Chirnside, Berwickshire, in 1887. Many new colours have been added to the section since.—W. C.

See also under VIOLET in *MEDICINAL HERBS.*

VIOLA RUST.—See *DISEASES OF PLANTS.*

VIOLA SPECIES.

Only a brief reference to these is necessary, for the culture of them is fully dealt with in the preceding and subsequent articles. The most important species are probably *V. cornuta, V. lutea,* and *V. tricolor*; from these the Violas of to-day have been derived. Then we have *V. odorata,* the SWEET VIOLET, and the parent of our Violets. Other species of some importance include *V. canina,* the DOG VIOLET, *V. hederacea,* the NEW HOLLAND VIOLET, and *V. sylvestris,* the WOOD VIOLET. A special word of praise must be given to *V. cornuta* and *V. gracilis,* both of which are useful for rockwork.

NEW SPECIES.

Viola Septentrionalis.—This bears faintly perfumed white flowers, which have violet lines on the base of the petals.

VIOLET.—See *MEDICINAL HERBS, VIOLETS,* and *WATER GARDEN: PLANTS FOR THE.*

VIOLET CRESS (*Ionopsidium acaule*. Nat. Ord. Cruciferæ).—This is one of the most delightful of hardy annuals, and it is seen at its best when filling a little shady recess in a fairly moist position in the rock garden. Sow in spring and thin the seedlings to a few inches apart; after which it will sow itself so freely that there is no difficulty in securing sufficient plants from year to year. It is a miniature plant of dainty and cheerful appearance, producing blue flowers freely all the summer. There is also a white variety of similar height to the blue sort, namely, 2 ins. Modern botanists now place the plant under the genus *Cochlearia*.

VIOLET WILLOW (*Salix daphnoides*). See TREES.

VIOLETS (Nat. Ord. Violaceæ). These grow in most of the temperate parts of the world, though many, especially in the new world, have no scent, or very little. They are not particular as to soil, for the writer of this article has had them do well on Bagshot sands, London clays, and the chalky soils of Hants and Dorset. They all seem to be very tenacious of life, as they will keep alive year after year, even when grown wild among grass.

The finest flowers are to be had on deeply worked loams, but even newly broken heath land that has had a liberal dressing of farmyard manure, and a thick coating of road-sidings, will give a remunerative return for the investment.

The writer grows many acres, the majority of which land is only deeply ploughed; but the best results are where the soil is deeply forked up and broken small with a new digging-fork, a liberal dressing of forty tons of manure to the acre being allowed. One thing is important: the manure must be evenly incorporated with the soil or the crop will be uneven; see that no large lumps of soil are left beneath the surface for the roots to come into contact with.

Planting.—All the large flowering singles should be planted 15–18 ins. apart, in the lines 2 ft. asunder, using single crowns with all lateral growths cleared off. The strong tips of runners soon root if planted in March and April, and if stock is short, the long runners cut into pieces and dibbed firmly in the soil, soon root and make nice plants, which will give some of the very largest blooms in autumn and winter, though they never grow into such huge plants as the strong, vigorous growths that come up from the base of old plants. All must be made firm when planting. All strong growers such as *La France* and *Princess of Wales* are planted in this way.

At our Violet farm we plant the Doubles or Parmas in the same way putting the crowns 12 ins. apart in the lines, and leaving the rows 2 ft. asunder, as it enables a wheel cultivator and hoe to be kept going up and down the lines, to keep down weeds and aerate the soil, which last is an essential point in good cultivation. If the surface soil is allowed to get hard and baked, the plants will stand still and will never be remunerative.

Summer Management.—Till July there is nothing much to do, save to keep the plants scrupulously clear of weeds. All the strong-growing, single varieties will then, however, begin to develop a lot of lateral growths from the main crown, and these should all be pulled off in order to enable the crown to build up its flower buds. We find that with such varieties as *La France* and *Princess of Wales*, one thinning, if done at the end of July, is sufficient; but others, such as *Luxonne* and

Ascania, are best done twice, since these make so many runners and in consequence do not develop such strong stems if allowed to spread out and grow as they would.

Doubles should be gone over three times; they then add to the centre crown, and produce the flowers early from August until May. They are not so easily grown as singles, it is true, nor are they so much sought after, but they are more productive under glass in mid-winter than are singles. If grown at all, they must be made to move on vigorously, or they will never pay the grower.

Lifting for Winter Protection.—All Double varieties such as *Louise, Brazza, Aster, Arthur, Parme*, etc., are best grown under glass in winter. They give a great quantity of flowers in autumn, it is true, but if grown out of doors frost stops them very early, and in many cases severely injures if not actually destroys them. For flowering in winter, plant them in frames or in side-borders of tomato-houses. To do this, nick out a trench about 6 ins. deep and somewhat sloping, placing the plants in the trench with a good ball of earth round them. All leaves will then lie away from the planter, and the soil can be levelled in with the spade and trodden firmly. The soil is then smoothed over again with the spade and made uniformly level, and another nick is made about 8–9 ins. from the first, and so on, till the whole of the frames or house-borders are full. After planting they must be well swamped with water, and kept always moist by a fine-rosed watering-can until new roots are made.

Harvesting the Flowers.—Flowers should be gathered with their full length of stem and tied in bunches of fifteen or twenty blooms. All flowers should be loosely arranged and a few leaves placed round each bunch rather low down the stems and tied tightly, since they take up moisture when loosely tied together. Six of the bunches may then be tied into one, to make a nice bouquet.

Varieties.—The following are strongly recommended:—

For General Use:—*Singles.*—Ascania (a sort with pointed purple-blue petals); La France (round blue petals); and Princess of Wales (a very large, long-stemmed sort, with blue flowers).

Doubles.—Conte de Brazza (pure white); Marie Louise (dark blue with white centre); Mrs Arthur (dark blue with stiff stems); and Swanley White (pure white).

For Market Purposes.—Varieties for this purpose are somewhat of a gamble, as in some years colour plays an important part. Sometimes there is a large demand for light blue, while in other years the main sale may be for dark blue and reddish-mauve sorts. We plant the following sorts most extensively:—

Singles.—Ascania (purple blue); La France (dark blue); Luxonne (purple blue); Mrs David Lloyd George (large, with petals of various colours); and Prince of Wales (dark blue).

Doubles.—Coleroonan (light blue); De Parme (mauve blue); Marie Louise (dark blue with white centre); Mrs Arthur (desirable blue); Mrs J. J. Astor (purple mauve); and Swanley White (pure white).—J. J. K.

VIOLETTAS.—See *Viola*.

VIPER.—See *Snakes*.

VIPER'S GRASS (*Scorzonera*. Nat. Ord. Compositæ).—The plants of this name are hardy biennials or perennials of no great value, but worthy of culture when the collection is extensive. They bear yellow flowers from May to August, on plants 1–2 ft. high. Probably

the most important species from a floral point of view is *S. mollis*, the SOFT VIPER'S GRASS. *S. hispanica* is not grown for its flowers, but for its roots, which are boiled similarly to Salsafy. Its culture is dealt with in the article on *SCORZONERA*.

VIRGINIA CREEPER (*Vitis quinquefolia*).—See *CLIMBING AND TRAILING PLANTS*.

VIRGINIAN POKEWEED or POKE-BURR (*Phytolacca decandra*).—See *PHYTOLACCA*.

VIRGINIAN STOCK (*Malcomia maritima*, Syns. *Malchomia* and *Malcolmia*. Nat. Ord. Cruciferæ). —This is a very popular annual, the most popular of all in the genus, though other species such as *M. bicolor* (pink and yellow), *M. Chia* (lilac-purple), and *M. littorea* (bright purple-pink) are sometimes grown. It and the other hardy annual species are all readily raised from seeds sown out of doors in March, but successional sowings are necessary if a long flowering period is desirable. As the seeds are very small a mere covering of soil is sufficient; and the seedlings should be thinned out to about 4 ins. apart. Virginian Stock may be had in a range of colour from white through mauve to purple and crimson. It flowers throughout the summer, and grows about 8 ins. high.

VIRGINIAN TOBACCO (*Nicotiana Tabacum*).—See *TOBACCO PLANT*.

VISCARIA.—Now included in the genus *LYCHNIS*.

VITIS.—See *CLIMBING AND TRAILING PLANTS* and *VINES*.

VITRIOL.—See *WEED KILLERS*.

VITRIOLATED BONES.—See DISSOLVED OR VITRIOLATED BONES under PHOSPHO-NITROGENOUS MANURES in *MANURES*.

VOLUMES.—See *ARITHMETIC AND GARDENING*.

VULNERARIA.—Now included in the genus *ANTHYLLIS*.

VULPIA.—Now included in the genus *FESTUCA*.

VUYLSTEKEARA.—See *ORCHIDS*.

W

WAHLENBERGIA (Syn. *Edraianthus*, TUFTED HAREBELL. Nat. Ord. Campanulaceæ).—These tufted plants with grassy leaves are all good rock garden plants, and may be easily raised from seeds sown in gentle heat in March.

Wahlenbergia dalmatica. — This biennial bears tufts of grassy leaves. Flowers rich violet in dense heads. Site sunny. Soil gritty, well drained. Flowering Period, June to August. Height, 3 ins.

W. graminifolia.—This biennial bears tufts of downy leaves. Flowers pale blue. Site sunny. Soil gritty. Flowering Period, May to July. Height, 3 ins.

W. Pumilio (Syn. *W. pumiliorum*). —This perennial bears tufts of very short silvery leaves. Flowers lilac or rosy-lilac. Site sunny. Soil rocky. Flowering Period, May to July. Height, 2 ins.

W. serpyllifolia (THYME-LEAVED HAREBELL).—This perennial bears tufts of narrow shining green leaves. Flowers deep violet-blue. Site sunny. Soil gritty. Flowering Period, June to August. Height, 3 ins.

W. vincaeflora (Syn. *W. gentianoides*).—This plant bears tufts of slender stems. Flowers deep blue. Site, half-shade, Soil rich gritty loam. Flowering Period, May to July. Height, 1 ft.

WAHOO (*Ulmus alata*).—See *TREES.*

WAITZIA.— See *EVERLASTING FLOWERS.*

WALL CRESS (*Arabis albida*).— See *ARABIS* and *CRESS.*

WALL GARDENING.

The healthy interest taken in the many beautiful mountain plants we comprehensively embrace within the term "Alpine" has led to an eager inquiry for information in respect of their cultivation and treatment under garden conditions. The most natural and also the most picturesque way of growing Alpines is unquestionably in a properly constructed rock garden. This is not usually a difficult problem in large gardens, but with those of moderate extent and especially with small gardens in or near large cities, it is not always a simple matter to combine variety with a near approach to pictorial effect, for the reason that a large number of the most effective rock plants are somewhat aggressive when placed in company with small growers, and unless close attention is paid to them in the growing season, they are most likely to crowd and smother them out. This difficulty is readily overcome, even in the smallest garden, by surrendering the rock garden to the choicest and rarest subjects, supplementing this by a dry-wall for the more vigorous and showy subjects. The advantage of the last named is that it takes up small space, it readily accommodates a great variety, and it introduces a pictorial feature of no mean order to the garden. Then again, dry-walls may have a place in gardens where space cannot be found for an elaborate rock garden; in such cases the most acceptable form is

that of a retaining-wall, as then it supplies an apparent reason for its existence, and the mass of soil that the wall supports yields a constant supply of moisture, so that even in the hottest summer the roots do not suffer from drought. Positions which suggest reasons for the existence of retaining-walls are when supports for terraces are required, or they may be introduced to force up the levels in forming a "sunk" garden, or the margins of a formal water-lily garden. Again, low walls radiating from the main paths, the borders level with the wall tops, may be introduced into many gardens, and with old rectangular stone slabs forming the pathways an extremely interesting garden results. Dry-walls may also be raised on level ground to form an enclosure much in the way we follow in planting hedges. In this case we take, for example, a wall that will be 5 ft. high when finished; this will require a base 3 ft. wide, and by allowing 2 ins. of "batter" on each side to every foot in height, the top will be 16 ins. wide when finished. In districts much subject to drought, the top should at least be 2 ft. wide, so that in a wall 5 ft. high the base would be 3 ft. 8 ins. wide. This gives a large body of soil to resist the drying influences of sun and air, while the increased width of the top allows artificial watering to be carried out with greater ease and with marked benefit to the plants. A wall of this nature differs from the retaining-wall in that both faces can be planted, as well as the top, and it is scarcely possible to conceive it as other than a charming addition to the garden.

The best material for erecting dry-walls is rough, unhewn stone direct from the quarry; blocks varying in size and thickness and of unequal lengths are to be preferred, and if the stone shows stratification so much the better. A dry-wall that is a prominent feature in the garden design should have the best stone procurable. For low walls it is often most expedient to use stone formed from broken paving slabs, or waste pieces from the local builder's yard; the only disadvantage is, that it takes longer to build; for all practical purposes the result is similar, as plants do equally well, and once they come to maturity, the stone is largely hidden by them.

Dry-walls may also be built with

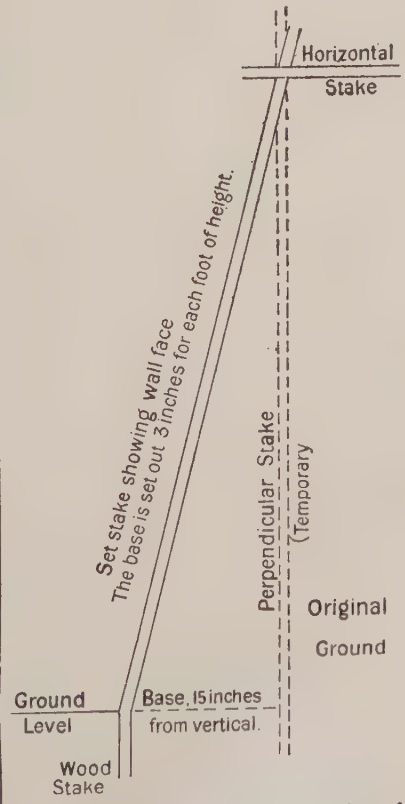

FIG. 1.—Method of finding position of wall face.

well-burnt bricks; these require exceptional care in bedding; they are best arranged laid flat, with the narrow end exposed,—this is what builders call "headers." With bricks, both joints and courses are of necessity very small, as the first object in all building is to secure stability of the structure, and this is readily endangered by leaving large joints and wide courses when dealing with bricks.

Construction.—In setting out a dry-wall the actual front edge where it meets ground-level is first marked out. Drive in a stout wooden stake at each end, perpendicular to the ground line (see Fig. 1). Ascertain the extreme height of the wall, and mark the perpendiculars at the given height. Now drive in a set stake on the higher ground above, where the wall top will come, and bisect the perpendicular at the point marked, nail these together, and make rigid. To find the "batter" of the wall face, take the number of feet in height, multiply by the factors three or four, expressing the result in inches. For example, a wall 7 ft. 6 ins. would give respectively $7\frac{1}{2} \times 3 = 22\frac{1}{2}$ ins., or $7\frac{1}{2} \times 4 = 30$ ins. This distance is set off from each perpendicular *at ground level*, and another stake is set up from this point and connected with each perpendicular at the wall top, thereby forming a diagonal line. This gives the set-back or "batter," and with a builder's line stretched between, the courses can be laid with ease and precision. The idea is illustrated in Figs. 2 and 3. Walls of irregular outline can be dealt with in the same way as straight walls; in this case, however, additional stakes should be used at all outstanding points. Having set out the wall face, proceed to open a shallow trench to receive the first layer of stone, and when the soil is heavy and water trouble is suspected, place a few land drain-pipes in the footing, some 12–15 ft. apart, and cover the inner end with enough ballast to carry off excessive water.

Arrange each of the wall stones so that the inner edge dips forward; make each stone quite rigid and firm by ramming with soil all joints and crevices behind. When one

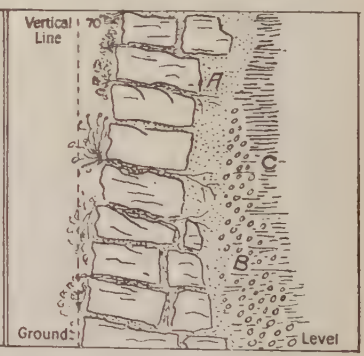

FIG. 3.—Section showing stones laid to form ledges.

NOTE.—Each stone is laid to dip inwards.

A—Special soil. *B*—Rough material to act as drainage. *C*—Natural soil.

course is laid, add a layer of prepared soil and proceed with second course, crossing or "bonding" the joints, making firm with soil as before, this process being continued until the wall is complete.

Planting.—This should be done during the building, as then larger plants can be used, and the roots can be led well behind the wall face. To plant effectively, a rough drawing of the main groups should be prepared beforehand (see Fig. 4); this eliminates haphazard work, and when the wall is finished, we do not find robust and vigorous varieties mixed up indiscriminately with weaker or more fragile sorts.

Aspect does not materially affect dry-walls except in the selection of suitable plants; positions open to sun and air should always be favoured, and overhead shade from either trees or buildings should be avoided, likewise proximity to trees like Elm, Chestnut, Beech, etc., as the roots of these soon overrun and exhaust the better soil in the wall.

Once the dry-wall is planted it requires little after attention; the first season it is advisable to spray the wall face morning and evening, with clear water delivered from a fine-rosed water-pot, care being taken not to wash the soil from the joints. As soon as growth is well advanced this may be discontinued. Then in regard to any vacancies that occur in the wall, these are readily made good either by using rooted cuttings, seedlings, or even seed itself; indeed, any or all of these can be used to plant the wall after building, when it is not practicable to plant while building is going on. In the case of seed, the best results follow by mixing the seed with about four times its bulk of good potting soil, sowing tiny pinches in the courses and joints where a plant is desired. With seedlings and rooted cuttings employ a sharp

pointed tool to open spaces to admit the roots, then fill in lightly with good turfy soil; with seed and small plants spraying with clear water is imperative until the plants are well established.

The soil employed for dry-walling calls for special mention, as, unlike in the rock garden, it is impossible by digging up the plants to renew it. Soil from chalk land gives the best results; in default of this, use good turfy loam, that has been stacked long enough to kill all grass life, in the proportion of—loam 4 parts, leaf-soil 1 part, crushed chalk or old mortar 1 part, and ½ part of sharp sand, the whole to be mixed together before using. Use this compost entirely in bedding the stones and filling the joints, and it may also be added behind the wall, mixing it with the soil *in situ* as the work proceeds.

To those who take up the cultivation of alpines seriously, the dry-wall has more to recommend it than its pictorial aspect; it offers a home for those capricious children of the mountains that are so sensitive to the humidity of our climate in winter, and compares favourably with the rock garden, as here no artificial contrivances are required to protect the plants. Grown in the dry-wall they are stronger in spring, break away earlier, and the harvest of blossom is the most generous one can conceive. This applies generally and is most marked among alpine plants having grey or woolly leaves.

WHAT TO GROW.

LIST OF PLANTS FOR SHADY WALL GARDENS.

Adonis vernalis.
Anemone apennina, blanda, nemorosa in variety.
Arenaria balearica, caespitosa.
Asarum europaeum.
Astrantia carniolica.
Campanula carpatica, pusilla.
Cardamine trifolia.
Cyclamens in variety.
Dicentra formosa.
Epimediums—for wall foot.
Erinus alpinus in variety.
Erodium Reichardi.
Erythroniums.
Funkias—for wall foot.
Galax aphylla (no lime in soil).
Haberlea rhodopensis (no lime in soil).
Hepatica angulosa, triloba.
Mazus Pumilio.
Mentha Requieni.
Myosotis in variety.
Nierembergia rivularis.
Omphalodes verna.
Ourisia coccinea (no lime in soil).
Oxalis enneaphylla (no lime in soil).
Polygala Chamaebuxus purpurea.
Primula capitata, farinosa, frondosa, latifolia, rosea, viscosa.
Ramondia all kinds.

FERNS.

Adiantum pedatum.
Allosorus crispus.
Asplenium Ruta-muraria, Trichomanes cristatum.
Blechnum spicant cristatum.
Ceterach officinarum, crenatum.
Cystopteris alpina (Regia), fragilis, montana.
Lastrea montana, Thelypteris.
Lomaria alpina.
Polypodium calcareum, Dryopteris, Phegopteris, vulgare in variety.
Polystichum Lonchitis, munitum.
Scolopendrium vulgare in variety.
Woodsia ilvensis, obtusa.

PLANTS FOR WALL GARDENS IN SUN.

Acaena Buchanani.
Acantholimon glumaceum.
Achillea argentea, Kelleri, rupestris, umbellata.
Æthionema coridifolium, grandiflorum.
Alyssum alpestre, montanum, saxatile citrinum fl. pl.
Androsace carnea, lanuginosa, sarmentosa.
Anthyllis montana.
Aquilegia glandulosa.
Arabis albida fl. pl., aubrietioides.
Arenaria montana, tetraquetra.
Armeria all kinds.
Artemisia brachyphylla splendens, pedemontana.
Asperula hirta, nitida.
Aster alpinus.
Aubrietias all varieties.
Calamintha alpina.

Campanula pulla, pulloides, garganica, G. F. Wilson, muralis, carpatica, pusilla, Steveni, turbinata, hayiodgensis, Profusion.
Cheiranthus Allionii.
Dianthus alpinus, arenarius, caesius, deltoides, fragrans, frigidus, graniticus, Lereschei, microlepis, neglectus, petraeus, plumarius, suavis.
Draba aizoides, dedeana.
Dryas octopetala.
Edraianthus dalmatica, pumiliorum, serpyllifolius.
Erodium amanum, chrysanthum.
Erysimum pulchellum.
Erythraea diffusa.
Gentiana acaulis.
Geranium argenteum, cinereum, Traversi, lancastriense.
Geum montanum.
Gypsophila cerastoides, repens.
Hutchinsia alpina.
Hypericum Coris, fragile, repens, reptans.
Iberis garrexiana, gibraltarica, Little Gem, Tenoreana.
Iris stylosa.
Jasione Jankae.
Leontopodium alpinum, sibiricum.
Linum narbonense, perenne.
Lithospermum Gastoni, graminifolium, prostratum.
L. prostratum Heavenly Blue.
Lychnis Viscaria splendens.
Morisia hypogaea.
Nepeta Mussini.
Œnothera riparia.
Onosma tauricum, albo-roseum.
Papaver alpinum, nudicaule.
Phlox amoena, reptans (verna), ovata, subulata all varieties.
Phyteuma comosum, orbiculare.
Plumbago Larpentae.
Potentilla ambigua, nepalensis, Wilmottiana.
Primula calycina, marginata.
Prunella webbiana.
Pterocallis pyrenaica.
Saponaria ocymoides splendens.
Scabiosa Pterocephala.
Sedum brevifolium, corsicum, dasyphyllum, kamtschaticum, pulchellum, rupestre, spurium.
Sempervivum arachnoideum, Laggeri, montanum.
Silene alpestris, Elizabethae, Schafta.
Stachys corsica, lanata.
Tanacetum argenteum.
Thymus lanuginosus, micans, Serpyllum in variety.
Tunica Saxifraga fl. pl.
Veronica Bidwillii. incana, rupestris.
Viola gracilis.
Zauschneria californica.

WALLFLOWER MILDEW.—See *DISEASES OF PLANTS.*

WALLFLOWERS (*Cheiranthus Cheiri.* Nat. Ord. Cruciferæ).—Seeds of Wallflowers may be sown outdoors from May to July; but to get good plants they should be sown thinly in lines, 12 ins. apart, during May, and transplanted when about 1–2 ins. high. If the ground is already dug, tread it firmly all over, then dibble the seedlings into

[1] Asterisk denotes species or varieties that succeed in part shade.

lines 12 ins. apart, and 6–9 ins. in the lines. The treading will ensure dwarf bushy plants, capable of flowering profusely the following May; or from autumn till spring in the case of the extra early Wallflowers. They should be transferred to their flowering positions as early in October as possible.

Wallflower Varieties.—We give below a selection of the best sorts :—

	Ins.
Blood Red.—Blood red. Spring.	12
Cloth of Gold. — Golden-yellow. Spring.	12
Darkest of All.—Maroon. Spring.	12
Eastern Queen.—Apricot, changing to rosy-pink. Spring.	12
Ellen Willmott. — Pure ruby. Spring.	12
Faerie Queen.—Pale citron yellow. Spring.	12
Fire King.—Vivid orange. Spring.	15
Giant Blood Red.—Large, blood red. Spring.	15
Giant Vulcan.—Brilliant crimson. Spring.	15
Giant Yellow. — Rich yellow. Spring.	15
Golden Monarch.—Golden-yellow. Spring.	12
Harbinger.—Brown. Winter and spring.	12
Ivory White.—Ivory white. Spring.	12
Linnaeus.—Creamy yellow, passing to pure white. Spring.	16
Orange Bedder. — Rich orange, shading to apricot. Spring.	9–12
Primrose Monarch.—Pale yellow. Spring.	12–15
Purple Queen.—Rich purple or ruby. Spring.	12
Rosy Gem. — Rose-carmine. Spring.	15
Vulcan. — Brilliant crimson. Spring.	9

The following, *Dwarf Red, Dwarf Yellow, Early Flowering Vulcan* (crimson), *Phœnix* (chestnut brown), *Primrose* and *Yellow Phœnix*, are all 9 ins. high; they flower from autumn till spring. All of these are named varieties of Sutton's early flowering strains. *Improved Double* (18 ins.) and *Double Dwarf Branching* (9–12 ins.) include many colours.

WATER GARDEN, THE.

Among the more modern developments of horticulture the water garden has taken an important place. It does not matter whether the site is of large extent, as of lake and river, or quite small as in such a place as may have only a trickle of water artificially supplied; either of these, and everything between, can be adapted for good use in the display of the many beautiful plants of the water and waterside. The diversity of circumstances and way of treatment may be as great as the nature and conditions of the place, but as in all good gardening the natural possibilities of the site have first to be considered and respected, for it is out of these that is formed, in the mind of the competent designer, the conception of the best form of treatment. The nature of the site will govern the main distinction, which is, whether the place is suitable for a free kind of planting on natural lines, or whether, in the case of a restricted area and where it will necessarily be near buildings, it will have to be of a purely formal character. In the first case let us suppose that the water supply is a natural one of pond and stream on the extreme outskirts of garden ground. Here, if the water has a naturally good edge, that is, an edge that is easily accessible and is not much above the water-level, all that is needed will be to clear adequate spaces for planting, leaving the natural growth, especially when it has any suitable character as of Sedge or Bur-reed, undisturbed. There are plants for all degrees of moisture. The noble water lilies for water of some depth, the fine things that thrive in quite shallow water, such as Water Plantain (*Alisma*), the great Water Dock (*Rumex*), some of the Irises, namely, the Yellow Flag, and the Japanese *Iris laevigata*,[1] Buck-bean, the Arrowheads, and the Flowering Rush (*Butomus*). Then there are the many plants that, though in no sense aquatics, rejoice on the banks of streams or ponds, where their roots can always feel the cool moisture of water soaking through the ground. Here may be grown many of the Spiraeas: the double form of our own Meadow Sweet (*Spiraea venusta*), with tender pink bloom and much the same habit; the larger *S. Aruncus* of Alpine torrents, with its handsome foliage and beautiful plumes of cream-white flowers; several of the tall Meadow Rues (*Thalictrum*); the rosy Willow Herb (*Epilobium*); and the crimson Loosestrife (*Lythrum*), the great yellow Loosestrife (*Lysimachia*), and its smaller relative the Creeping Moneywort. Here also is the place for the tall Yellow Mimulus and for Globe Flowers (*Trollius*); the Marsh Marigold (*Caltha*), with the yellow Himalayan Primrose (*Primula sikkimensis*) having nodding sulphur bells, and the Japanese Primrose (*Primula japonica*), of a rather rank magenta colouring in the type form but with varieties of good white and various degrees of pleasant pink colouring. Then there is the Siberian Iris both purplish-blue and white, with some garden improvements, all happy in damp ground, and *Saxifraga peltata* with its great roundish leaves.

Where spaces are large, good use can be made of the great Cow Parsnip (*Heracleum*); the more recently introduced *H. mante-*

[1] Or *Iris Kaempferi*.—Editor.

gazzianum is an improvement on the older *H. giganteum*.[1] The still larger foliage of the giant Gunneras requires cautious placing as it is almost out of scale with ordinary vegetation. In waterside planting, Ferns should not be forgotten. The best for general use are the Royal Fern (*Osmunda*), the graceful Lady Fern, and the Dilated Shield Fern.

The shape of the bank next the water is well worth considering. It is often of a steep, rounded form that seems to plunge suddenly into the water. Such a bank is far from pretty. It gives a sense of insecurity and does not admit of convenient planting. Where there are such banks it is well worth while to make a complete alteration and to shape the ground afresh, so as to leave a level grassy pathway some 7 ft. wide, only raised enough above the water to be sound and dry; thus providing easy access, security, and the best opportunity for good planting. This is shown in Fig. 1.

FIG. 1.

A natural running stream, especially if it flows fast over a shallow pebbly bed, with sides either naturally near the water-level or purposely made so, is one of the very best settings for beautiful plants. It can often be so arranged that the path shall cross it from time to time, either by well-set stepping-stones or by a simple plank or log bridge. But it is most desirable, especially in places that have a natural character, such as the edges of ponds and streams, that a wise restraint should be observed about the numbers of different plants that are to be seen at a glance. If many different kinds are seen together, restful enjoyment of their beauty will be lost. One good thing at a time in fair quantity, or two at most, is the better way, as, for example, Double White Meadow Sweet with Water Forget-me-not, and to let this go on for some yards, and then, after an interval, to pass on to some other grouping, either of one kind of plant, or two in combination. [This point needs emphasising. Many water gardens are completely spoilt by having too many plants showing at the same spot.—ED.] In stream planting also the finer of the hardy Ferns should not be overlooked: the Royal Fern (*Osmunda*), the Lady Fern, and the Dilated Shield Fern. These are best seen on the further side of the stream; in fact, the view of many of the plants will be better and more comprehensive from the opposite bank. In this way the stream has the advantage of the pond, unless the pond is quite a small one.

It sometimes happens that the only available water is a mere trickle at the bottom of a deepish ditch. When this is the case, and when labour can be expended, the sides can be cut down as before suggested and the spare soil thrown out to form raised banks; one side having the space for a path only a little above water-level, while the other is varied by taking the form of an

[1] Now known as *Heracleum villosum*. —EDITOR.

easy bank beginning at the water's edge. The little stream may also be widened and its bed floored with small stones or flattish slabs. The path and the accompanying treatment of the banks can move from side to side so as to give different aspects and points of observation. If it is desired that the place shall be enclosed from outer view, the banks formed by throwing up the waste soil should be planted with some kind of bushy growth, for preference Holly, with Whitethorn, Blackthorn, Spindle Tree, and other shrubs of like character; then the bank on the path side would be an admirable place for growing some of the better kinds of wild Blackberry.

When the water garden is in a more restricted space, or where, as is often the case, it is desired to have water plants near the house or in close connection with formal gardening, it will take the form of a built tank, symmetrical pool, or miniature canal; or a series of tanks may be connected by a narrow rill that may be stepped over. The edges will either have a flat pavement or a raised curb of wrought stone. There is sometimes hesitation about having a tank deep enough for water-lilies on account of danger to children, but there is a way of building the outer yard or two of the tank that minimises the danger and is in any case desirable. This is to have the outer portions only a foot deep for a yard at least from the edge (see Fig. 2). This

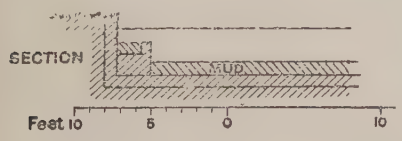

Fig. 2.

also provides a way of having plants in pots that thrive in shallow water; such as the noble Water Plantain and Arrow-heads; or, if the wall to the deeper level is carried up so as to retain 4–5 ins. of soil for the plants to root in, it will be all the better. In all cases where water is employed in conjunction with masonry, as in such tanks or rills or in fountain basins, it is important that the water-level should be placed high and carefully maintained. Nothing is more common or has a more slovenly and uncared-for appearance than a half-empty tank. If it is used for dipping, and the supply is not automatically continuous, it should be turned on at once.

The gardens of the Italian Renaissance show some of the finest examples of the use of water in connection with garden architecture; but it rarely happens in our islands that there is an opportunity of using such vast masses of water; for there are in Italy examples where whole rivers were turned into the garden to form rushing cataracts, water stairs, water theatres, and endless arrangements of fountain, rill, and pool; lasting monuments to the inventions of the designer and the resource and skill of the hydrostatic engineer.—G. J.

WATER GARDEN: Plants for the.

There are a great many beautiful plants suitable for the water garden which are of easy culture, and below we deal with the most meritorious:—

Arrow-head (*Sagittaria*. Nat. Ord. Alismaceæ).—No river or pond side is complete without an example of this plant, which bears attractive, glossy, arrow-shaped leaves. It will live planted in water a foot deep, or where currents only lave its elegant stems. Plant in March, enclosing the roots in a thin cardboard box which will rot away before long,

filling the box with a compost of loam, clay, sand, and old manure, adding a heavy stone to keep it down on the bed of pool or stream. The best sort is—

Sagittaria variabilis. (Syn. *S. japonica*).—This bears white flowers from July to October. Height, 2 ft. Its variety, *flore pleno*, is double white.

Bamboo (*Bambusa.* Nat. Ord. Gramineæ).—The sorts suitable for the water garden are dwarf plants and trees, delighting in rich, damp soil, but liking sunshine. They are apt to be spoilt by cold cutting winds, but may be successfully planted in late March or April. We recommend the following :—

Bambusa Fortunei aurea.—This has golden variegated foliage. Height, 3 ft.

B. Metake.—A foliage plant with greenish-yellow florescence in August. Height, 12 ft. The variety *variegata* has cream and green foliage.

Cape Pond Flower (*Aponogeton distachyum.* Nat. Ord. Naiadaceæ).—This is the fragrant white "weed" that beautifies so many ponds, rivers, lakes, and mill-backwaters during late summer, continuing even into winter. It will succeed in sun or shade, but must be kept severely in check, if near water-lilies. It is propagated by root division and planted in the same way as the Arrow-head, or in sunk pots in water 1–3 ft. deep. If the greater depth exists, a mound of stiff soil should first be made, so as to place the roots only just below the level at the start. The hillock will be washed away as the plants develop strength. Good sorts for the water garden include—

Aponogeton distachyum.—This bears white, Hawthorn-scented flowers from April to October. Height, 9 ins. The variety *roseum* has pink and white flowers.

Creeping Jenny (*Lysimachia Nummularia.* Nat. Ord. Primulaceæ).—A first-rate creeping or trailing plant for wet ground, with yellow flowers, blooming from April to August. Height, 3 ins.

Crowfoot (*Ranunculus.* Nat. Ord. Ranunculaceæ).—The kinds of Crowfoot mentioned here, all of which are hardy and luxuriant both in foliage and flowers, need but to be planted in November or March, and supported by rustic stakes, with ties of green tape, to prepare a grand flower show during spring and summer. *Ranunculus aconitifolius flore pleno* is familiar to most people as FAIR MAIDS OF FRANCE, and will become quite a bush, covered by massed heads of snowy rosette-shaped blooms. *Ranunculus acris plenus* is the old-fashioned BACHELOR'S BUTTONS, and can only be seen in perfection where the roots have a deep run of moist soil, though it is often starved in ordinary borders. *Ranunculus Lingua*, a sort with very fine leaves, requires planting in the mud just beside or beneath the water in November. We give a brief description of the three sorts below :—

Ranunculus aconitifolius fl. pl.—This bears white flowers from May to June. Height, 2½ ft.

R. acris plenus.—This bears bright gold flowers from April to September. Height, 3 ft.

R. Lingua.—This bears yellow flowers from June to July. Height, 4 ft.

Day Lily (*Hemerocallis.* Nat. Ord. Liliaceæ).—Day Lilies are so called because individual blooms of the trusses only open and last in perfection for a day. They create beautiful colour masses in damp places in the water garden, or even under deciduous trees, and are best planted in November. Good sorts for the present purpose include—

Hemerocallis aurantiaca major.—This bears apricot-coloured flowers

from June to August. Height, 4 ft.

H. citrina.—This bears pale yellow flowers from June to August. Height, 4 ft.

H. Dumortierii.—This bears orange flowers from May to July. Height, 2 ft.

H. flava.—This bears pure gold flowers from June to August. Height, 3 ft.

H. fulva.—This bears copper-bronze flowers from June to August. Height, 3 ft. Its variety, *variegata*, bears coppery-orange flowers, and has foliage margined cream.

Flags (*Iris*. Nat. Ord. Iridaceæ).—A small pool could be made sufficiently beautiful by being fringed with irises, reeds, and periwinkles alone; or some varieties of iris will look delightful rising out of St. John's Wort, against a background of foxgloves.

The true yellow WATER FLAG (*Iris Pseudacorus*) will thrive in a bog or grow right up from the bottom of a pond. In ordinary soil, however, the rhizomes should be planted about 2 ins. deep. To establish plants actually in water, obtain a clump, and plant preferably in a heap made up of equal parts of loam, leaf-mould, coarse sand, and old decayed manure, bringing this to within 6 ins. of the surface of the water. The best planting period for this, and indeed most irises, is November.

The JAPANESE IRIS (*Iris Kaempferi*) is best located on the verge of sun-reached water, some margin from which the roots can stretch out naturally to the wetter soil of the bed. It will grow successfully in 9 ins. of water, however.

The SIBERIAN FLAG (*Iris sibirica*) has fine green grass-like foliage, and makes an excellent display, as well as being quite hardy in moist ground. It should be planted not more than 2 ins. deep, and 6 ins. or more apart, in November.

We briefly describe some of the species most suitable for the present purpose below:—

Iris Kaempferi (JAPANESE IRIS).—This bears flowers of combined colours, in shades of blue, lavender, white, crimson, purple, grey, rose, and yellow, from July to August. Height, 2½ ft.

I. Pseudacorus (WATER FLAG).—This bears yellow flowers from June to July. Height, 3½ ft. Two good varieties of it are *alba* (cream), and *Bastardi* (lemon yellow).

I. sibirica (SIBERIAN FLAG).—This bears flowers in combined colours, and selfs of lavender, violet, blue, white, and yellow, from June onwards. Height, 3 ft. The sub-species, *orientalis*, and its varieties *Blue King* (blue) and *Snow Queen* (white), are better than the type.

Other Flags that will succeed in moist soil and are thus suitable for the drier portions of the water garden include—

Iris graminea.—This bears white and blue flowers in June. Height, 1½ ft.

I. Monnieri.—This bears gold and white flowers in August. Height, 4 ft.

I. ochroleuca.[1]—This bears yellow and white flowers in June. Height, 6 ft.

I. spuria.—This bears blue flowers in July. Height, 4 ft.

The MONSPUR HYBRIDS, bearing flowers in shades of blue, violet, lavender, etc., from July onwards, and growing about 4 ft. high, are also suitable.

Forget-me-not (*Myosotis*. Nat. Ord. Boraginaceæ).—*Myosotis palustris*, bearing blue flowers from May to August, and growing 1½ ft.

[1] *Iris orientalis* of Kew.—EDITOR.

in height, is a very useful water-garden plant.

Foxglove (*Digitalis*. Nat. Ord. Scrophulariaceæ).—This is able to bear floods in the water garden, or it may be planted where the river currents lave its lower leaves at times. The varieties of *Digitalis communis* (*D. purpurea* below) can be sown in seed-beds in April, and transplanted the same autumn. The following are useful for the water garden as well as for general borders :—

Digitalis lutea.—This bears yellow flowers in July. Height, 2 ft.

D. purpurea (Syn. *D. communis*).—This may be had in purple, mauve, rose, crimson, cream, or white forms. It blooms from May to August. Height, 2–5 ft.

Globe Flower (*Trollius*. Nat. Ord. Ranunculaceæ).—This is an exceptionally fine subject for the present purpose, and should be placed on terrace tiers, or little mounds of well-manured loamy soil, raised actually upon the boggy edges of the pool or river. As the earliest summer months find it in bloom, it is well to plant as early as possible in November. The following are useful for the present and for general purposes :—

Trollius acaulis.—This bears yellow flowers tinged with sepia, in June. Height, 6 ins.

T. asiaticus.—This bears deep golden flowers from May to June. Height, 1½ ft.

T. europaeus.—This bears golden flowers from April to June. Height, 1½ ft.

T. giganteus.—This bears lemon-yellow flowers from April to June. Height, 3 ft.

Goat's Beard (*Astilbe*. Nat. Ord. Saxifragaceæ).—This should be quite a feature of every water garden. It will bear cold climates or warm, but does best in semi-shade, and is most successfully planted in October. The leaves of all are highly ornamental. A few good sorts include—

Astilbe chinensis.—This bears rose flowers on crimson stems in July. Height, 4 ft.

A. Davidii.—This bears rose or red-purple flowers from July to August. Height, 5 ft.

A. grandis.—This bears white flowers from May to September. Height, 6 ft.

A. japonica.—This also is white, and flowers in July. Height, 2 ft.

A. rivularis.—This bears yellowish-white flowers from May to September. Height, 3½ ft.

Golden Rod (*Solidago*. Nat. Ord. Compositæ).—This is an extremely hardy subject and flourishes in the sun or the shade, bearing a wealth of feathery plumes which last for a long period on the plants. *S. gigantea* is notable as possessing handsome silky seed vessels that remain attractive during the winter months. These subjects should be planted in November or February in good soil near the water's edge. We recommend the following :—

Solidago altissima.—This bears yellow flowers from August to September. Height, 8 ft.

S. canadensis.—This bears yellow flowers in August. Height, 4 ft.

S. gigantea.—This also bears yellow flowers in August. Height, 6 ft.

S. procera variegata.—This bears yellow flowers from July to September. Height, 8 ft.

Grass of Parnassus (*Parnassia*. Nat. Ord. Saxifragaceæ).—This can be grown in boggy soil at the very edge of the water, and is best planted in March. Two suitable sorts are—

Parnassia fimbriata.—This bears white flowers in July and August. Height, 9 ins.

P. palustris.—This bears white flowers from June to August. Height, 6–9 ins.

Groundsel (*Senecio.* Nat. Ord. Compositæ).—The following are very hardy if planted in sunshine-reached bogs, and are meritorious by reason of the late season at which they continue to yield their showy blossom spikes :—

Senecio Clivorum.—This bears yellow flowers from July to October. Height, 5 ft.

S. pulcher.—This bears rosy-carmine flowers from July to December. Height, 3 ft.

Knot Grass (*Polygonum.* Nat. Ord. Polygonaceæ).—There are over 150 species of Polygonum, of small, medium, tall, or towering growth. Many thrive in ground sometimes inundated, or usually wet, and are best planted in March or October. As, however, there are many better subjects, we only describe one species, namely—

Polygonum sachalinense.—This bears greenish-white flowers from July to September. Height, 12 ft.

Lily (*Lilium.* Nat. Ord. Liliaceæ).—Lilies cannot be omitted from any water garden, however small, as they have a special charm near the water. A tall trio will give dignity to the head of a small pond, while the loveliness of thickets of dwarfer species is unsurpassable, whatever the position may be in which they are planted.

The following species should have a damp, but not water-logged soil in a semi-shady site. *Lilium chalcedonicum* and *L. monadelphum* should be planted in November, 5 ins. deep and 4 ins. apart each way, after which a heap of cinders should be put over them for the winter. The American Swamp Lily (*Lilium superbum*) should be planted 6 ins. deep, and 1 ft. apart each way. The Giant Himalayan Lily (*Lilium giganteum*), which has immense, heart-shaped leaves, as well as delightfully scented flowers, must be planted 6 ins. deep also, and 15 ins. apart each way. It should be set in a site which is always wet, and one in shade. We briefly describe the best lilies for the present purpose below :—

Lilium chalcedonicum.—This bears scarlet flowers in July and August. Height, 3 ft.

L. giganteum (Giant Himalayan Lily).—This bears white flowers tinged with purple, in August. Height, 10–12 ft.

L. Martagon (Martagon Lily, or Turk's Cap Lily).—This bears purple and black flowers in July. Its variety *album* is white. Height, 2½–3 ft.

L. monadelphum.—This bears lemon-yellow flowers in July. Height, 3–5 ft.

L. pardalinum (Panther Lily).—This bears orange-scarlet flowers spotted with purple, in July. Height, 5–8 ft.

L. superbum (American Swamp Lily).—This bears orange-red flowers spotted brown, in July. Height, 5–10 ft.

Loosestrife (*Lythrum.* Nat. Ord. Lythraceæ).—This is a family of giant plants that can be set as specimens in bogland, or at the water's edge, to blossom all through the late summer and autumn. They are best planted in November. The following are the best :—

Lythrum Salicaria.—This, and its variety *superbum*, bear deep rose and red-purple flowers from July to September. Height, 5–6 ft.

Marsh Marigold (*Caltha palustris.* Nat. Ord. Ranunculaceæ).—Water may flow over this plant's roots, or merely permeate the surrounding soil, but in either case it will grow well. The best planting period is October, and it may be remarked

that the varieties *flore pleno* (double gold) and *purpurascens* (orange flushed with maroon) are better than the type. All bloom from June to July, and average 1–1½ ft. in height.

Meadow Sweet (*Spiraea*. Nat. Ord. Rosaceæ).—Practically every kind of Meadow Sweet will thrive in moist borders in or out of the water garden if planted in October or November, so that it is impossible to name all the valuable sorts here. The following half-dozen should, however, be grown before all others :—

SpiraeaAruncus.—This bears white flowers in June. Height, 5 ft.

S. astilboides.—This bears cream-coloured flowers in July. Height, 5 ft.

S. gigantea.[1]—This bears white flowers in July. Height, 10 ft.

S. japonica.[2]—This bears rose-coloured flowers in July. Height, 4 ft.

S. Lindleyana.—This bears white flowers in August. Height, 10 ft.

S. palmata.—This bears rosy-crimson flowers in July. Height, 4 ft.

Monkey Flower (*Mimulus*. Nat. Ord. Scrophulariaceæ).—This is an admirable little plant for clothing moist banks, or making carpets near the water, and only requires to be planted in good rich soil in March. The four best species are briefly described below :—

Mimulus cardinalis.—This has scarlet-crimson flowers from June to August. Height, 2 ft.

M. cupreus.[3]—This bears orange flowers from June to August. Height, 1 ft.

M. luteus.—This bears scarlet-crimson flowers from May to August. Height, 1 ft.

M. radicans.—This bears white flowers from May to July. Height, 6–12 ins.

Orchid (*Orchis*. Nat. Ord. Orchidaceæ).—All the members of this family are fascinating gems for boggy places where the soil is lightened by peat or decayed leaves, only requiring to be planted in March. The three best species are—

Orchis foliosa.—This bears purple-crimson flowers in May. Height, 2 ft.

O. latifolia.—This bears purple flowers in June. Height, 1½ ft.

O. maculata superba.—This bears purple flowers in June. Height, 2 ft.

Periwinkle (*Vinca*. Nat. Ord. Apocynaceæ).—This is a family of trailers almost indispensable for water gardens, to cover margins, but seen at their best, perhaps, when overhanging banks or low walls so as to touch the stream or pool. Plant in March or October. There are plain green-leaved or variegated forms of the following available :—

Vinca major.—This bears purplish-blue flowers from June to August. Height, 2 ft.

V. minor. — This bears blue flowers, and its variety *alba* bears white flowers, from June to August. Height, 1 ft.

Phlox (*Phlox*. Nat. Ord. Polemoniaceæ).—Both the summer and autumn blooming herbaceous Phloxes are such moisture-loving subjects that they will live and do well in soil that is nearly always wet. Their vivid colours make them specially valuable for bold effects by lakes and ponds. All they require is to be firmly planted in November or March. We recommend the following :—

[1] *Spiraea camtschatica* of Kew.—EDITOR.

[2] *Astilbe japonica* of Kew.—EDITOR.

[3] *Mimulus luteus cupreus* of Kew.—EDITOR.

Phlox decussata.[1]—This may be had in red, pink, crimson, salmon, vermilion, orange, purple, lavender, mauve, cream, grey, maroon, or pure white forms, and blooms from July to October. Height, 2–5 ft.

P. suffruticosa.—The colours and period of blooming are the same as the above. Height, 1–3 ft.

Primrose (*Primula.* Nat. Ord. Primulaceæ).—The Woodland Primrose (*Primula vulgaris*) should dot the mossy banks of streams and lakes. The handsome Japanese Primrose (*Primula japonica*) revels in moist shady situations. Plant the former in October, and the latter in March. There are countless species of great beauty, such as *Primula Beesiana, P. Parryi,* and *P. sikkimensis,* though these are of somewhat difficult culture, many of them requiring a peaty soil. The two best for the present purpose are—

Primula japonica.—This may be had in crimson, pink, or blush-white forms, and blooms in May. Height, 1½ ft.

P. vulgaris.—This bears flowers of typical Primrose yellow in April. Height, 9 ins.

Reedmace (*Typha.* Nat. Ord. Typhaceæ).—All watersides need masses of foliage plants, and the present plant affords a welcome relief to gay flowers. The leaves are flat and very long, and from these rise the velvety heads of purplish florescence that turn black with age. The best planting period is October, and it is well to note that the heads may be improved in size if the plants are fed from time to time with weak manure water. The best species is—

Typha latifolia.—This bears greenish-purple flowers which change to black, from July onwards. Height, 5–7 ft.

Rhubarb (*Rheum.* Nat. Ord. Polygonaceæ).—This is a family of handsome giant plants suitable for planting near large lakes, or by the sides of very large ponds. They are valuable for their foliage, and are best planted in March. The two best species for the present purpose are—

Rheum collinianum.—This bears crimson flowers in July. Height, 3 ft.

R. officinale.—This bears yellowish-white flowers in July. Height, 10 ft.

Rockfoil (*Saxifraga.* Nat. Ord. Saxifragaceæ).—This is suitable for planting in moist soil, but not within actual reach of the water, and the best time to set it is November. We recommend the following species :—

Saxifraga cordifolia.—This bears rose flowers in March. Height, 1½ ft.

S. peltata.—This bears pale pink or white flowers in May. Height, 2 ft.

S. umbrosa (London Pride).—This, as is well known, bears pinkish-white flowers from May to July. Height, 1–1½ ft.

Royal Fern (*Osmunda regalis.* Nat. Ord. Filices).—This bears the greenest of all green waterside foliage. It is a lovely fern requiring a semi-shady site, and is best planted in October. Height about 2½ ft.

St. John's Wort (*Hypericum.* Nat. Ord. Hypericaceæ).—This is a well-known foliage plant which clothes the ground with glossy foliage all the winter, and supplies good floral effects all the summer. It may be successfully planted from October to March. The best water garden sorts are—

Hypericum calycinum.—This bears

[1] *Phlox paniculata* of Kew.—Editor.

yellow flowers from May to August. Height, 2 ft.

H. japonicum.—This bears yellow flowers in May and June. Height, 1½ ft.

Solomon's Seal (*Polygonatum.* Nat. Ord. Liliaceæ).—This is so graceful when fully grown, and so attractive is its fresh green foliage when shooting up in the spring, that all watersides should have an abundance of it. It is of very easy culture, and only requires to be planted in its permanent position in November. The best species is—

Polygonatum multiflorum.—This, known also by the name of DAVID'S HARP, bears white flowers in May and June. Height, 3 ft.

Sweet Flag (*Acorus.* Nat. Ord. Araceæ).—This is a graceful plant which will thrive in bog or water in cold or genial localities, and is best planted in March. The best sorts are—

Acorus Calamus (MYRTLE GRASS).—This bears greenish-yellow flowers in July. Height, 4 ft.

A. Calamus striatus aureum.—This has greenish-yellow flowers and bold variegated foliage. It blooms in July. Height, 2½ ft.

Violet (*Viola.* Nat. Ord. Violaceæ).—This can be used for studding banks and gentle slopes near the water; but though the roots like moist soil, they cannot live in ground that becomes flooded, and in wet districts are best planted in April, otherwise September is a good time for the work. The best sorts for the present purpose are—

Viola odorata (SWEET VIOLET).—This bears violet, red purple, blue, or white flowers from March to May, and often again in the autumn. Height, 3–6 ins.

V. suavis alba.—This bears white flowers in June. Height, 4 ins.

Water Lily (*Nymphaea.* Nat. Ord. Nymphaeaceæ). — See our special article on *WATER LILIES.*

Willow Herb (*Epilobium.* Nat. Ord. Onagraceæ).—This is a family of useful plants for making thickets close to the water. The best planting periods are November or March. We recommend the following species :—

Epilobium album. — This bears white flowers in July and August. Height, 5 ft.

E. angustifolium (ROSE BAY).—This bears rosy-crimson flowers in July. Height, 4–6 ft.

Winter Heliotrope (*Tussilago fragrans.*[1] Nat. Ord. Compositæ).—Although this subject only bears insignificant lilac-white blossoms in January and February, these are deliciously scented, while the carpet its glossy green leaves make is of the utmost value. The best planting period is March, in order that the plant may become well established before the winter comes on. Its height averages only 9 ins.

M. H.

WATER GLASS.—See POTASSIUM SILICATE in *POTASH AND POTASSIUM COMPOUNDS,* and SODIUM SILICATE in *SODA AND SODIUM COMPOUNDS.*

WATER HEMLOCK (*Cicuta virosa.* Nat. Ord. Umbelliferæ).—This is a hardy herbaceous moisture-loving perennial suitable for the wild or water garden. It bears white flowers in July, and averages 2–4 ft. in height. A dangerous plant with the same English name, but botanically known as *Œnanthe crocata* (Syn. *Œ. apiifolia*), is referred to in our article on *ŒNANTHE.* The two are not synonymous.

WATER HEMLOCK (*Œnanthe crocata*).—See *ŒNANTHE.*

WATER HICKORY (*Carya aquatica*).—See *TREES.*

[1] *Petasites fragrans* of Kew. See article on *PETASITES.*—EDITOR.

WATER-LEAF. — See *HYDROPHYLLUM.*

WATER LILIES (*Nymphaea.* Nat. Ord. Nymphaeaceæ).—Of all the phases of modern gardening none is more charming and attractive than water gardening; and of all the plants used in this connection none is more beautiful and important than the Water Lily.

Many species of Nymphaea inhabit the fresh waters of Europe, Asia, Africa, and Australia, but few are suitable for cultivation out of doors in our own land, except the COMMON WHITE WATER LILY (*Nymphaea alba*) of our lakes and ponds, and its rose-coloured variety (*Nymphaea alba rubra*), often called the SWEDISH WATER LILY. Other species sometimes grown are *N. odorata,* and the variety *rosea,* which, crossed with *N. alba,* probably gave origin to the magnificent coloured hybrids raised by the late M. Latour Marliac in France, and by other raisers in America, and which have completely revolutionised water gardening. *N. pygmaea,* and its variety *helvola,* are tiny kinds suitable for very shallow water by the margins of sunny ponds or fountain basins. *N. tuberosa* is a strong-growing American species suitable for fairly deep water. At the present time, however, the hybrids or seedlings of various beautiful colours are the most important, and a list of them will be given below.

Culture.—This is not difficult given the essentials of a sunny sheltered position, water varying from 1 ft. to 3 ft. deep, and abundance of rich mud in the bottom. Many of the stronger growers will flourish in much deeper water, but the point of interest to most people is the fact that very deep water is not necessary. In cold districts where prolonged hard frost is common and the water is likely to be frozen to a considerable depth, it would be advisable only to attempt the strongest growers which are able to rise to the surface of deep water, but whose rhizomes would be safe from frost in the mud below.

It is not within the province of this article to discuss the construction of artificial ponds and lakes, as this matter is dealt with in our article on *WATER GARDEN, THE,* but if their ultimate object is to form a home for Water Lilies the above essentials must be provided. It is not advisable to utilise swiftly running water, but there should be sufficient movement to prevent stagnation.

Most of the hardy Water Lilies grow by means of rhizomes which spread about among the mud, emitting long fleshy roots. As received for planting they usually consist of a short piece of rhizome with a growing point. The best method is to plant this in an open wicker-basket, using good loam mixed with a little rotten cow manure; sufficient room being left on the top of the basket for a couple of fairly heavy stones to keep it from floating when placed in the water. If the rhizomes should be very small and weak it is better to grow them on in small tubs for a time until strong enough to put out in the pond or lake. The water in the tubs should be kept sweet and clean by adding a few gallons every two or three days.

In subsequent years Water Lilies give little trouble. The strongest growers will in time become a mass of "Crowns," with the result that many of the leaves in the centre of the mass will be pushed above the water and the flowers consequently hidden; also fewer flowers are produced when this condition arises.

The remedy is to thin out the crowns, an operation obviously only possible in comparatively shallow water. The best time to work is just when growth is commencing in the spring and the young leaves can be seen rising to the surface. A sharp spade is a suitable tool with which to cut through the rhizome at some convenient place behind the growing point. When the water becomes muddy a little practice will enable the operator to find the crowded rhizomes by feeling about with the spade. A strong rake or drag is usually necessary to wrench the separated portion out of the mud.

Water Lilies are not often subject to insect pests or fungoid diseases, but occasionally during a hot, dry summer Aphis attacks the leaves. This may be disposed of by spraying once or twice with a weak insecticide. Sometimes a fungoid disease attacks the young leaves, causing them to become discoloured and to decay before full development,—the only remedy is to cut them off as near the base as possible, an operation which cannot be done except in fairly shallow water. Happily such attacks are uncommon and need deter no one from enjoying the most beautiful of all aquatic plants.

What to Grow.—The following species and varieties can be cordially recommended, though new ones are being constantly introduced; and it should be noticed that the figures in brackets do not signify the height of the plants but the depth of water in which they are best planted :—

Nymphaea alba (COMMON WHITE WATER LILY).—White flowers from June to August (*D.* 3 ft.). Its variety *rubra*, the SWEDISH WATER LILY, is red.

N. Arc-en-ciel.—Pink flowers from June onwards (*D.* 1½–2 ft.).

N. atropurpurea.—Deep crimson purple flowers from June to September (*D.* 3 ft.).

N. Aurora.—Rose and yellow flowers, changing to salmon from June onwards (*D.* 1½–2 ft.).

N. Brackleyi rosea.—Pale rose flowers from June to September or later (*D.* 1½–2 ft.).

N. chrysantha.—Yellow flowers, deepening to orange-red from June onwards (*D.* 3 ft.).

N. Colossea.—Soft pink flowers in May and throughout the summer (*D.* 3 ft.).

N. Ellisiana.—Deep rose-red flowers from June to September (*D.* 1½–2 ft.).

N. Escarboucle. — Vermilion-red flowers in June and subsequent months (*D.* 3 ft.).

N. Froebelli.—Large deep crimson flowers from June onwards (*D.* 1½–2 ft.).

N. fulva.—Yellow flowers flushed pink, changing to orange-red from June onwards (*D.* 1½–2 ft.).

N. Gladstoniana.—Large white flowers from end of May onwards (*D.* 3 ft.).

N. Gloriosa.—Carmine flowers in summer and autumn (*D.* 1½–2 ft.).

N. James Brydon. — Rosy-red flowers in June and throughout the summer (*D.* 1–2 ft.).

N. Laydekeri.—The varieties *fulgens* (deep red), *purpurata* (deep crimson), and *rosea* (soft pink, deepening to carmine) are the best, and bloom from June onwards (*D.* 6–12 ins.).

N. marliacea.—The varieties *albida* (white), *carnea* (flesh), *chromatella* (yellow), *flammea* (crimson-purple), and *ignea* (rich crimson) are the best, and bloom from June onwards (*D.* 3 ft.).

N. odorata.—White flowers in summer (*D.* 1½–2 ft.). Its variety *rosea* has rose-pink flowers.

N. Richardsoni.—White flowers in June and onwards (*D.* 3 ft.).

N. sulphurea.—Yellow flowers in June and July (*D.* 1½–2 ft.).

N. tetragona. — White flowers June to August (*D.* 6–12 ins.). Its variety *helvola* has yellow flowers.

N. tuberosa.—Large white flowers from June to September (*D.* 3 ft.).

N. William Doogue.—Soft pink flowers from June onwards (*D.* 1½–2 ft.).

N. William Falconer.—Ruby-crimson flowers in June and throughout the summer (*D.* 1½–2 ft.).

J. W. B.

WATER LOCUST.—A name applied to the genus GLEDITSCHIA, more especially *G. aquatica.* See *TREES.*

WATER MEASURES.—See *WEIGHTS AND MEASURES.*

WATER OAK (*Quercus nigra*).— See *TREES.*

WATER THYME (*Elodea canadensis.* Nat. Ord. Hydrocharidaceæ). — This plant is by some people highly prized as an aquatic. It may be grown in the same way as *WATER LILIES,* on which we give a separate article.

WATER : TO SOFTEN.

Soft water is much better than hard for watering plants, and is much pleasanter to wash soiled hands in after working in the garden. There are two classes of hardness which may be treated as follows :—

Permanent Hardness.—This as a rule contains sulphates of lime and magnesia, and is regarded as difficult to soften. This is not the case. A strong solution of washing soda should be made with rain water, and this poured into a tub of the hard water a little at a time. A certain milkiness will result, and the whitish material should be allowed to settle. The process is then repeated, and repeated until no more white matter settles out, and when it has been filtered it will be found to be perfectly soft.

Temporary Hardness.—This is the most common form of hardness, and the water contains bicarbonate of lime in some quantity. Strong lime water will soften it, and this should be added in the same way as the above until no white matter settles out, when it will be found that the water is soft.

It should be mentioned that water softened in these amateur ways should not be used for drinking purposes.

WATERER'S GOLD WEEPING HOLLY (*Ilex Aquifolium aurea pendula*).—See *HOLLY.*

WATERING.

Watering is the artificial application of moisture to soil for the benefit of plants growing therein. Domestic plants, especially when grown in pots or under glass, are wholly dependent on the cultivator for their water supply, and the seeing to this branch of work occupies a large portion of the gardener's time. Rain water is the best to use, especially for pot plants, being "soft," that is, it contains no lime, and is warmer than spring or well water. River and pond water come next, while that from wells and springs, including tap-water in town areas, is the worst. It is often "hard"—contains much lime—and is distinctly cold. Such water should stand in tubs or open vessels for at least twenty-four hours to become aerated and raised to the level of the general temperature. The use of water much colder than the soil plants are growing in tends to give a check to the roots, resulting in crippled growth and yellow foliage. Too cold water can always be readily warmed by the addition of hot from the kitchen kettle or boiler.

The golden rule in watering crops and plants of all kinds, whether in pots or not, and whether growing

indoors or out, is thoroughly to moisten all the soil occupied by the roots. The quantity used is quite immaterial. A tablespoonful may be sufficient for a small pot plant; a couple of gallons may be required by a subject growing in a tub. The principle remains the same. Watering by driblets at stated intervals is bad gardening; with pot plants it leaves the mass of soil unwetted; with outdoor crops it encourages surface rooting and leaves them peculiarly susceptible to injury from drought. Well-moistened soil acts as a reservoir in dry weather, and if surface evaporation is checked by the use of the hoe or by a mulch of manure, lawn mowings, etc., quite a long drought can be passed in comparative safety. Should the water supply be too little for well watering the whole of a given crop, then do a portion thoroughly, rather than give a little to the whole.

Soil irrigation is useful in the case of fruit trees, shrubs, etc., where the surface is hard or sloping and flooding cannot be adopted. Driving a crowbar into the soil for a depth of 2 ft. or 2 ft. 6 ins. at 3 ft. intervals and then filling the holes with water is a good method. Climbers and fruit trees against walls, also window boxes, often need watering in rainy weather owing to the direction of the rain being such that they receive none.

Outdoor seed-beds should be heavily watered over-night, the seeds being sown the next day; this is much better than trying to water after sowing and generally lasts long enough for germination to take place. Seed pots and pans are best watered by submerging them to the soil-level in a vessel of water, and holding thus till the water percolates upwards through the drainage hole.

Plants growing in pots and hanging baskets, whether indoors or out, need constant attention, especially in warm weather. Once thoroughy dry, irreparable damage is often the result, and in any case the plants suffer. Bud dropping at a later stage is often traceable to such neglect or oversight. Watering in greenhouses is commonly done in the early morning, but in hot summer weather it is necessary to go through the collection again in the late afternoon, and water all that are becoming dry. Plants in a root-bound condition will need two or three times as much water as similar subjects not so well rooted. In dry weather it is allowable to stand very thirsty subjects in saucers and keep these filled with water.

In summer it is not usual to overwater plants, but at other seasons, and especially in low temperatures, this may accidentally be done. The preventive is to test before applying. This is done by rapping the pot with the knuckles or with a padded stick. If a dull heavy sound follows no water is required; if a sharp ring is given off then apply the watering-pot. Do not water by rule of thumb; in winter especially give no water at all unless really needed. Few plants should be dried off entirely, and these are confined to bulbs and tubers. Other deciduous subjects, such as fuchsias and ferns, should have the soil prevented from becoming dust dry. Cacti and other fleshy plants are best not watered during the winter unless shrivelling is apparent.

Plants that accidentally become thoroughly dry are best revived by immersing in a tub for twenty minutes. Hanging baskets are best watered by this method to ensure thorough saturation.

Overhead watering of plants either

by a rosed watering-pot or a syringe is very beneficial in greenhouses during late spring and early summer, imitating the April shower and encouraging a similar growing condition of the atmosphere. Five to 6 p.m. is a suitable hour, closing or partially closing the house at the same time for two or three hours. Tropical plants and orchids need copious waterings and syringings during the growing season, those with aerial roots largely depending on atmospheric moisture for their supply.

The instrument commonly used for watering plants is known as a watering-pot, and is usually fitted with a broad perforated detachable end known as a "rose," which breaks the water up into a spray. There are many varieties and sizes of watering-pots suited to varying requirements, but for indoor work a light size with a shallow body and long spout serves well; for outdoor use a larger one with a short spout is advisable. In applying water, whether to pot plants or garden ground, always hold the spout low and pour over the soil, otherwise the surface may be much disturbed and soil washed away. With pot plants do not pour into the plant's centre but on the surrounding soil. In the case of newly potted plants the rose should be used till the soil has become settled.—H. A. S.

WATERPROOFING.

Garden work often entails a certain amount of getting about in wet weather. Now and again it is useful to waterproof the old garments that are worn in the open. A useful way of doing this is briefly described below. Make a weak solution of size or glue and water. This should set similarly to a badly made jelly when it is cold. Whilst the mixture is hot throw in a lump of alum, allowing half an ounce of this to every pint of the solution. Then add a breakfastcupful of soapsuds to the same quantity of hot solution, and brush it over the garments whilst still hot. It will be found to render them completely waterproof, and the addition of soap prevents the glue from hardening the material. Any kind of cloth can be rendered waterproof by rubbing the underside with a lump of beeswax. A sufficient amount of the wax should be applied to the cloth to give it a slightly greyish appearance.

Making Boots Watertight.—Dry feet are of supreme importance to the gardener, and on this account it is desirable to render boots waterproof. The liberal application of almost any kind of grease will of course keep out the damp. But in time, however, this treatment will rot the leather, and the boots will get into a very unsatisfactory state. A well-tried preparation is made as follows: Mix together ½ pint of linseed oil, 4 oz. of mutton fat, 3 oz. of clean beeswax, and 2 oz. of resin. These ingredients should be mixed in a pot over a slow fire, and the preparation applied when the boots are clean and dry. It is brushed on whilst warm, but

it must not be put on very hot or it will shrink the leather. One application is sufficient to make the boots absolutely water-tight for a considerable period, during which the leather remains in a pliant state. Boots that have been waterproofed should never be placed near to a fire when they are damp. By far the best plan is to wipe away the external moisture with a dry cloth and then stand them in a cool place.—S. L. B.

WATSONIA (Nat. Ord. Iridaceæ). This is a very beautiful free flowering bulbous plant for pot culture in a cool greenhouse, and is increased by offsets. It should be potted in good loamy soil, leaf-mould, and sand. Temperature needed, 40–50° F.

Greenhouse Species :—*Watsonia angustifolia.*—Delicate pink. Flowers in June. Height, 1–1½ ft.

W. densiflora.— Rose. Flowers in May. Height, 1–1½ ft.

W. iridifolia Ardernei.—Large pure white flowers borne on elegant spikes. Specially recommended for cutting, as the cut flowers will remain in good condition for a fortnight. Flowers in June. Height, 2–2½ ft. high.

W. Meriana. — Bright rose. Flowers in May. Height, 1½–2 ft.

W. plantaginea.—Pink. Flowers in June. Height, 1–1½ ft.

WAUKEGAN JUNIPER (*Juniperus Sabina procumbens*).—See *TREES.*

WAX GOURD.—See *ORNAMENTAL GOURDS.*

WAYFARING TREE (*Viburnum Lantana*).—See *SHRUBS.*

WEATHER AND GARDENING. There is a certain class that pours out scorn on the type of man known as "the fair-weather gardener." Up to a point the scorn is applaudable, but after that it is ridiculous. While we may admire men who work on the land in all weathers to some extent, we have to admit that it is really very little use working out of doors in awful weather.

Take, for instance, two examples of gardening work—digging, and sowing seeds.

The fair-weather gardener says that he will not dig frost and snow into the ground. The all-weather gardener does not hesitate to do so, however; he says that his garden must be dug somehow or other by a certain date. So he digs the frost and snow in.

He is wrong, however, and the fair-weather gardener is right. Snow and frost if dug into the land are both exceedingly harmful, and it would be far better to leave the land alone on such days, or to do some necessary work such as stacking manure, or wheeling it on to the ground when the land is hard. It is a different matter to dig during rain. That is only unpleasant. The fair-weather gardener is wrong to leave his land alone then, if the season is getting late, for it shows he is afraid of a wetting; he probably thinks he will melt like a lump of sugar or a piece of salt. But he will not. Again, immediately after a very heavy thaw the land is best left alone, since to dig in mud is almost as bad as to dig in frost.

In the question of seed sowing much the same holds good. The all-weather gardener first of all proceeds to construct for himself a time-table of work, based on facts given him by some other equally old-fashioned all-weather gardeners. This time-table fixes dates for sowing every kind of seed. The all-weather gardener puts the time-table up in his potting shed and keeps rigidly to it. To him it does not matter what sort of state his

soil is in, provided it is not frozen too hard to cut with his hoe; he must get his seeds in by those certain fixed dates. I have known men to rake off snow to sow parsnips, and to plant peas and broad beans in a soil little else than a puddle. They expect good crops, and they sometimes even get them, more by fluke than by anything else.

The fair-weather gardener is again more sensible. He looks at his soil, he tests it in the usual way by clenching and releasing it in his hand, and when it binds into a ball of mud he rightly concludes that it is not the least use sowing seeds. If he is energetic he takes steps to dry the surface of his soil by frequent deep hoeing, and if not he waits for the weather to mend. Even though he sows a little late he has a much better chance of getting a really good crop than has his brother the all-weather man—a point worth remembering.

From the above it will be seen that the all-weather man should be more chary about scorning his fair-weather brother than he is. There is a time for doing all things connected with gardening, as the Calendars in this book amply show. But if successful results are ultimately to be attained, the weather conditions at the start must be of a suitable nature for carrying out the work. I could go on to speak of the folly of doing any form of planting in bad weather, but the foregoing will be sufficient to make gardeners study the weather when working.—E.

WEED KILLERS.

These are essential if there is much in the way of pleasure grounds under the gardener's care. Various proprietary articles are on the market, useful though expensive, and thus some gardeners prefer to make their own. This is easily done as follows:—

Carbolic Acid.—A 1% solution of the pure acid (*i.e.* 1 part acid to 99 parts of water bulk for bulk) makes quite an effective weed killer, but the pure acid being difficult to obtain in some places the common commercial acid can be substituted and 1 lb. of this mixed with every 14–15 gallons of cold water. Care must be taken that the acid does not float on the surface but is evenly mixed with the whole, and on no account must any come in contact with the clothes or flesh, as it is very corrosive. The liquid is applied through the fine rose of a watering-can to weedy gravel paths, etc., and a good soaking given.

Caustic Soda.—A solution of this made by dissolving 1 lb. in 10 gallons of water is recommended by some as a weed killer, but is still rather in the experimental stage. Its use should be limited to very hot weather on gravel paths, and a good soaking given as before.

Copper Sulphate.—Copper sulphate, or BLUE STONE, has an undoubtedly corrosive effect on green leafage, as is evidenced by scorching if potato-spraying liquids are improperly mixed. This may be turned to advantage as a weed killer in districts where this material is cheap. The use is still in the experimental stage, but a solution of 1 lb. per 5–10 gallons of water may be used with some success in hot weather.

Salt.—This is of undoubted value as a mild weed killer. It is best applied dry and scattered freely over weedy paths on the first really hot day in the early summer. The weeds will wither in a few hours, and can then be got up without much difficulty. HOT BRINE, made by dissolving as much salt as is possible

in each gallon of boiling water, is also a splendidly effective weed killer if a thorough soaking of the boiling liquid is applied to young weeds on paths through a fine-rosed can.

Sodium Hydrogen Sulphate. — This also is of great value as a weed killer. A strong, almost saturated solution should be made as the material is cheap, and this applied hot through a fine-rosed can.

Vitriol.—A 4% solution of oil of vitriol (Sulphuric Acid) in water makes a weed killer of enormous value—it is probably the most useful of all. The acid must not be measured in a metal utensil, but in one of pot or well-glazed earthenware to prevent damage. The water should be measured into a wooden tub and the acid poured very slowly into it with constant stirring. If the water-can is used this must be repainted all over before and after use on account of the corrosive action of the acid. This solution may be used at any time, a thorough soaking being given as before.

Besides these materials there are one or two mixtures which make good weed killers. Many gardeners swear by a mixture of equal parts quicklime and salt applied in dry weather, but this is objectionable in wet districts. A good solution for watering paths may be made by boiling about 1 lb. of White Arsenic and the same weight of Caustic Soda together in 4–5 gallons of water until a clear solution results. Then filter and bottle the liquid, using a pint of this stock solution per gallon of water.

Warnings on Weed Killers. — If any of these liquids remain over after use it should be bottled and labelled "Poisonous" to prevent accidents. These bottles should not be left about, but are best locked up in the tool shed.

The clothes and hands must not come in contact with the majority of the liquids, or bad burns will result.

The liquids must be kept away from live edgings, grass verges, dwarf hedges, etc., or the latter will be greatly damaged, if not destroyed.—E.

WEEDING.

From the beginning of April to the end of October the gardener should never cease weeding, since, if he does, his land and crops will be robbed right and left of food and water. Many gardeners err by reason of the fact that they start weeding too late in the season. They let the ground assume a verdant meadow-like appearance and then, late in May, instead of early in April, they start attacking the weeds. They are too late. Already the soil has been robbed of food and moisture, already the crops have suffered for lack of air and light, and the prospects of the best results have vanished into space. Had weeding been done earlier, in fact as soon as the rows of crops were sufficiently above the ground to show their presence, much less labour would have been needed, and the ultimate results would have been better in every way.

The writer well remembers some weeding experiences, a record of which is published elsewhere. He thinks that gardeners on the whole are a very lazy lot as regards weeding. It is so easy when one sees a few weeds between the lines of our crops to say: "These are not worth troubling about." But soon these few neglected weeds seed, and breed hundreds more. It is surely a case of being in time.

There are many modes of weeding. And here opinions differ. The present writer is fully convinced of

the enormous value of the Dutch hoe as a weeding tool, except in certain cases. There are weeds such as trefoil, wild strawberry, ground ivy, and twitch which no sensible gardener should attempt to raise with a Dutch hoe or any other hoe. Such weeds should be got up with a weeding fork, and broken as little as possible, since every little piece broken off seems capable of growing. The use of the hoe for such weeds serves to break them up into many pieces—just the opposite of what should be done. Then again the Dutch hoe is very little use in the case of long-rooted weeds such as dandelions. It only cuts their crowns off; then they immediately form a callus and three or four more crowns. A digging fork is the right tool to use for raising dandelions and similar deep rooting weeds.

But for surface rooting weeds, not in seed, such as charlock, groundsel, chickweed, feverfew, etc., the Dutch hoe is a splendid tool to use. A few sharp reaches or cuts with this removes the top growth of the weeds, and a deeper cut (which should in every case immediately follow the surface one) throws out most of their roots.

Weeds should not be left lying on the surface soil except on hot dry land, and even then it is a risk. The gardener should remember what terribly strong constitutions weeds have and treat the subject of weeding with the respect due to it. If the weeds are left lying about on cold damp soils even in the strongest sunshine, they may suddenly shoot into growth again. On hot dry soils the weeds soon wither when hoed up, but the first shower of rain frequently makes them start growing again. Flowers are prematurely formed and seeds ripened, so unless the gardener gets rid of weeds in some satisfactory manner immediately after hoeing them up, he is likely not to have to do his work merely over again, but ten times over again. No saying is truer than that which tells us that "one year's seeding means ten years' weeding."

Hand weeding demands a little consideration. There are some portions of the garden where the hoe cannot be used and where the weeder would be tiresome. In such cases rather than let the weeds get a hold and spoil the effect, as well as spoil the plants, the weeding should be done by hand. In very dry weather this is almost impossible if the work is to be done thoroughly, owing to the grip the weeds have on the soil. The best time, and the safest as regards the growing plants, is to do the work immediately after, or during a heavy shower. The weeds are firmly gripped towards their base with the right hand, and a slight but sudden twist brings them out root and all. Care must be taken not to leave the roots of the weeds in the ground, otherwise there will be more trouble in the course of a week or two.

Our aim should be not to let the weeds ever grow to any size. To keep the ground clear, there is no better practice than to hoe the borders and vegetable garden regularly at least once, or, better still, twice each week. Weeds cannot grow in the loose friable layer of soil obtained by frequent hoeing, and advantage of this fact should be taken.

There is only one safe way of destroying deep rooted and creeping weeds, also weeds which are in seed. That is by burning them. The method of working is dealt with in a separate article, to which article (*Burning Garden Rubbish*) the reader is referred.

Soft weeds which are not in flower may also be burnt, but it is wasteful. The best method of disposing of these is dealt with in the article on *Vegetable Matter*, to which the reader is asked to refer.

E. T. E.

See also *Orchards: Making and Management of; Trees: Raising from Seed; Vegetables: General Considerations.*

WEEDS.

The kinds of weeds with which a gardener has to contend are determined by various factors, such as locality, soil, climate, and cultivation. The number of species that may occur as garden weeds is very large, but comparatively few are so generally found as to need special consideration. The most important of these are as follows:—

Annual Meadow Grass (*Poa annua*. Nat. Ord. Gramineæ).—Annual. Occurs in tufts. Leaves bright green, usually somewhat wrinkled in places. Found in all sorts of situations, though the individual plants are often very short lived. Flowers all the year round. Height, 2–6 ins.

Means of Control.—Constant hoeing, to prevent seeding.

On Paths.—The weeds should be hoed or cut down, and the paths then dressed with one of the following weed killers:—

(1) Common salt, applied dry, sufficient to whiten the surface.

(2) Washing soda, applied in a solution containing 5 lb. in 10 gals. of water.

(3) Bluestone (copper sulphate), 5–10 parts to 100 parts of water.

(4) Carbolic acid, 1 part to 100 parts of water.

(5) Sulphuric acid, 4 parts to 100 parts of water. This needs special care in handling, as it is very corrosive and poisonous. It should be mixed in a wooden vessel, and applied as rapidly as possible with a can, which must be washed out directly after use.

(6) Patent weed killers of various descriptions, of which many are advertised.

Bent Grass (*Agrostis vulgaris* and *A. alba*. Nat. Ord. Gramineæ).—Perennial; tufted or creeping. In the latter case it roots freely as it spreads. Leaves flat, rather rough on the upper side. Flowers very small, borne on a slender, dainty, branched head called a panicle, which is sometimes spreading, sometimes close, and often tinged with brown. Flowers throughout summer. Height, 2–24 ins.

Means of Control.—Constant hoeing, hand pulling, and entire removal of plants by digging.

Bindweed (*Convolvulus arvensis*. Nat. Ord. Convolvulaceæ).—Perennial, with slender, creeping underground stems, climbing by means of twining aerial stems. Leaves stalked, rather heart-shaped. Flowers bell-shaped, white or pink. Fruits containing four large seeds. The twining stems tend to strangle the plants up which they clamber, and to pull them to the ground in many cases. Flowers summer.

Means of Control.—Underground stems should be dug out and burned, and all green stems be pulled up or hoed out whenever seen.

Black Bindweed (*Polygonum Convolvulus*. Nat. Ord. Polygonaceæ).—Annual; climbs by means of twining stems. Leaves heart-shaped. Flowers white or pink, in loose, stalked clusters. Fruits black, triangular. Flowers summer and autumn.

Means of Control.—Constant hoeing, and hand pulling where necessary.

Uses.—The seeds are very similar to those of buckwheat, and have been used for the same pur-

poses, including the preparation of flour for human consumption.

Black Nightshade (*Solanum nigrum.* Nat. Ord. Solanaceæ).—Usually annual, sometimes biennial. Stems angular; much branched. Leaves stalked and angular. Flowers small, white, and in clusters. Fruit a black berry. Flowers summer and autumn. Height, under 2 ft.

MEANS OF CONTROL.—Constant hoeing.

Buttercup.—See CREEPING BUTTERCUP.

Chickweed (*Stellaria media.* Nat. Ord. Caryophyllaceæ).—Annual. A much-branched trailing plant with opposite leaves and small white flowers. Forms an abundance of seed, and is often very troublesome in kitchen gardens. Can be recognised by a row of hairs that runs up one side of the stem from leaf to leaf, and then changes its position to the opposite side between the next pair of leaves. Flowers practically all the year round.

MEANS OF CONTROL.—Constant hoeing.

Coltsfoot (*Tussilago Farfara.* Nat. Ord. Compositæ).—Perennial, with stout creeping underground stems. Leaves heart-shaped and radical, the undersides covered with white cottony down; appear after the flowers. Flower heads pale yellow; arise on separate stems, with small leaves or scales arranged on the stalks. Fruits with a pappus or tuft of hairs or plumes, which aid in distribution by the wind. Flowers early spring.

MEANS OF CONTROL.—The underground stems should be removed as much as possible during cultivation, and the flower heads be cut early to prevent seeding. The weed is often associated with poor soil, and judicious manuring may help to eradicate it in such cases.

Common Orache (*Atriplex patula.* Nat. Ord. Chenopodiaceæ).—Annual, varying much in height and habit. Numerous branches, which come off at right angles to the stem and to one another. Leaves stalked and angled, with broad bases, often covered with a whitish meal. Flowers greenish and insignificant, in slender spikes. This is a most variable plant in every way. The colour may be anything from a very deep green to a light whitish-green, though it is rarely as white as Fat Hen, which it often resembles rather closely. Flowers summer and autumn.

MEANS OF CONTROL.—Constant hoeing.

Common Sow-thistle (*Sonchus oleraceus.* Nat. Ord. Compositæ).—Annual. A strong growing, succulent plant, with prickly leaves and a milky juice which exudes whenever any part is broken. Leaves have no stalks and clasp the stem with their broad bases. Flower heads numerous, flat, pale yellow. Fruits with a tuft of hairs or plumes, by which they are scattered by the wind. Flowers summer and early autumn. Height, 1–3 ft.

MEANS OF CONTROL.—Constant hoeing. If any plants become established they should be dug out, as the roots are stout and run deeply in the ground.

Couch Grass (*Agropyron repens*, or *Triticum repens.* Nat. Ord. Gramineæ).—Perennial. One of the most pestilent of grasses. Is easily recognised by the white or brownish creeping underground stems which send out roots and aerial stems from every joint. The growing tip is characteristically sharp and pointed, and is well adapted for piercing its way through the soil or even through any obstacle that comes in its way, provided it be not too hard. Flowers summer. Height, 1–2 ft.

MEANS OF CONTROL.—This weed should be dug out and destroyed whenever seen. It is useless merely to pull up the green tops, as fresh shoots constantly arise from below ground, and every joint can produce a new plant if it be broken off.

USES.—Makes a useful compost if decomposed with lime. The underground stems can be used as fodder for farm stock, as horses and cattle will eat them readily, and they may also be fed to pigs. They contain much nutritive matter which can be extracted in the form of a starchy powder resembling arrowroot, suitable for human food.

Creeping Buttercup (*Ranunculus repens*. Nat. Ord. Ranunculaceæ). —Perennial. A creeping plant that roots at the joints or nodes from which the leaves spring. Leaves divided, with the top segment removed to a little distance from the lower two. Flowers yellow, closely resembling those of the common tall buttercup. Fruits numerous, arranged in clusters at the top of the flowering stalk. Plant is covered with scattered soft hairs. Flowers summer and autumn.

MEANS OF CONTROL.—Constant hoeing and removal by digging.

Creeping Thistle (*Cnicus arvensis*. Nat. Ord. Compositæ). — Perennial, with creeping underground stems. A very prickly plant. Leaves spiny, cut up at edges. Flowering heads dull purple, several on a stem. Fruits small, plumed. Plant spreads partly by the plumed fruits, but chiefly by the creeping underground stems. Flowers summer. Height, 2–4 ft.

MEANS OF CONTROL.—See BINDWEED.

USES.—The seeds of the thistle family are a favourite food of small, hard-billed birds, especially goldfinches.

Daisy (*Bellis perennis*. Nat. Ord. Compositæ). — Perennial. Leaves rather spoon-shaped with toothed edges, arranged in a rosette pressed flat on the ground. Flowers crowded into solitary close heads, the outer florets being white, tipped with pink, and the inner florets bright yellow. Fruits not provided with plumes. Flowers practically all the year round. Height, about 2 ins.

MEANS OF CONTROL.—Hoeing and hand weeding.

On Lawns.—Great improvement in weedy lawns may be effected by dressing in spring with sulphate of ammonia at the rate of 1 lb. per square rod, mixed with fine dry soil. This application may be repeated every month from April to July.

If a pinch of salt or sulphate of ammonia be placed in the crown, the weed will be poisoned and die off, but this has the disadvantage of making unsightly patches and leaving the large roots in the soil. It is better to root out as many weeds as possible, not merely cutting them off below the surface. If large bare patches are left they should be raked over, scattered with fine soil and resown with grass seeds.

Dandelion (*Taraxacum officinale*. Nat. Ord. Compositæ).—Perennial. Roots long, thick and tapering. Leaves in a rosette, long, rather narrow, edges cut into triangular lobes which generally point downwards. Flowers yellow, crowded into solitary heads. Fruits rather prickly, plumed, carried by the wind. Whole plant possesses a milky juice. Flowers spring and autumn. Height, usually 6–8 ins.

MEANS OF CONTROL.—*On Lawns*. —See DAISY.

On Paths.—See ANNUAL MEADOW GRASS.

USES.—Blanched leaves can be eaten as salad. In some places

the roots are dried, roasted, and ground for use as a substitute for coffee. They are also much used in medicine.

Deadnettle.—See RED DEADNETTLE.

Dock (*Rumex sp.*, usually *R. crispus* and *R. obtusifolius*. Nat. Ord. Polygonaceæ).—Perennial, with stout rootstocks penetrating the ground to some distance. Leaves stalked, rather large, with thin membranous stipules which form sheaths round the stems. Flowers numerous, but rather insignificant, usually reddish, clustered on more or less branched stems. In the fruit the winged perianth persists as a covering to the three-angled nut, which is usually dark brown in colour. Flowers summer. Height, 2–3 ft.

MEANS OF CONTROL. — Hand pulling to remove the entire plant is the only effective remedy. Extra deep rooting plants may have to be lifted with a fork.

Enchanter's Nightshade (*Circaea lutetiana*. Nat. Ord. Onagraceæ).—Perennial, with creeping underground stems. Leaves opposite, stalked, heart-shaped, thin and downy. Flowers very small, white or pink, somewhat resembling London Pride in appearance. Fruits two seeded, covered with small hooks. This is not a very common weed in gardens, but is exceedingly troublesome where it occurs, on account of the persistent vitality of the underground stems. Flowers summer. Height, 1–1½ ft.

MEANS OF CONTROL.—See BINDWEED.

Fairy Rings are caused on lawns by various kinds of fungi, chiefly toadstools. A multitude of delicate branched white threads, called mycelium, spread through the soil and periodically throw up fruiting bodies, which are familiarly known as toadstools. As the mycelium spreads outwards from a central point, and the fruiting bodies arise from the youngest part, on the outer edge, a ring is formed. The fairy rings can be traced even when no toadstools are visible, as the grass near the edge is usually of a very dark green colour.

MEANS OF CONTROL.—Slaked lime should be applied at the rate of 1–2 tons per acre. As fairy rings often indicate poverty of soil, infested lawns should be well manured. The Board of Agriculture has recommended 1 ton of slaked lime applied in winter; 3–4 cwt. of superphosphate, 3 cwt. kainit, 4½ cwt. nitrate of soda in early spring; followed by 1–2 cwt. superphosphate and 1 cwt. nitrate of soda in late spring (quantities given are per acre). If lawns are damp, sulphate of ammonia may well be used instead of nitrate of soda.

Fat Hen (*Chenopodium album*. Nat. Ord. Chenopodiaceæ).—Annual. Leaves stalked and rather variable in shape, simple. Flowers in dense, leafy spikes, greenish, unattractive. Fruits dark coloured and bun-shaped, remaining enclosed in the floral envelope. Plant is very pale green and is usually covered with a white meal, especially on the flowers and underneath the leaves. Flowers summer and autumn. Height, 1–2 ft.

MEANS OF CONTROL. — Constant hoeing and hand weeding.

USES.—Pigs will eat it greedily, and sheep and cattle do not dislike it. In some parts of Eastern England and in Scotland it is occasionally boiled for use as a vegetable. Commercially the seeds are valuable in the manufacture of shagreen.

Fool's Parsley (*Æthusa Cynapium*. Nat. Ord. Umbelliferæ).—Annual. Leaves finely divided. Flowers white, arranged in flat heads called

umbels, with two or three narrow reflexed green leaflets or bracts at the base of each cluster of flowers. Poisonous, and not very common as a garden weed. Flowers summer and autumn. Height, 1–2 ft.

MEANS OF CONTROL.—Constant hoeing.

Goosegrass (*Galium Aparine*. Nat. Ord. Rubiaceæ).—Annual. Stems long and straggling. Leaves simple, long and narrow, arranged in whorls of six or eight. Flowers white and inconspicuous, followed by all-like fruits. The whole plant scrambles by means of reflexed hooks which occur on every part. Flowers summer and autumn.

MEANS OF CONTROL.—Constant hoeing and hand pulling.

USES.—In Sweden the seeds are dried, roasted, and used as a substitute for coffee, and the dried plant is sometimes infused in hot water to make a herb tea. From very ancient times the rough stalks have been used as a filter for straining milk, and this still survives in country districts in England when a proper sieve is not available. A red dye has been obtained from the roots.

Goutweed (*Ægopodium Podagraria*. Nat. Ord. Umbelliferæ).—Perennial, with creeping underground stems. Leaves coarse, compound, with segments in threes. Flowers numerous, white, arranged in crowded umbels. Where this weed is allowed to spread it carpets the ground densely and chokes out everything else. Flowers summer. Height, 1–1½ ft.

MEANS OF CONTROL.—See BINDWEED.

Greater Bindweed (*Calystegia sepium*. Nat. Ord. Convolvulaceæ).—Perennial, clambering over hedges and bushes, spreading by creeping rootstocks. Stems slender. Leaves stalked, large, rather triangular and pointed. Flowers large, white, and bell-shaped. Fruits containing four seeds. Flowers summer.

MEANS OF CONTROL.—See BINDWEED.

Greater Plantain (*Plantago major*. Nat. Ord. Plantagineæ).—Perennial, with a short, stout rootstock. Leaves grow from the ground-level in the form of a rosette, from the middle of which the slender flowering spike rises. Leaf stalks grooved. Leaves often 5 ins. long, broad and oblong, marked with five, seven, or nine strong ribs. Flowers small and greenish, arranged closely along the flowering stalk. Fruits containing several irregular dark coloured seeds. Flowers summer and autumn. Height may reach 1 ft.

MEANS OF CONTROL.—*On Lawns*.—See DAISY.

On Paths.—See ANNUAL MEADOW GRASS.

USES.—Seeds are much valued as food for cage birds. The leaves have certain healing properties, and have been applied to wounds.

Groundsel (*Senecio vulgaris*. Nat. Ord. Compositæ).—Annual. One of the most pestilent garden weeds. Erect and branching. Leaves cut up, rather irregularly lobed. Flowers yellow, in numerous tiny heads. Fruits provided with plumes, by which the seeds are scattered far and wide by the wind. Flowers all the year round. Height, 6–12 ins.

MEANS OF CONTROL.—Constant hoeing or hand pulling. It is specially important to prevent this weed from seeding.

USES.—Is much employed as a food for cage birds. The plant was once much in favour for medical purposes, but it has now fallen into disuse.

Hoary Plantain (*Plantago media*. Nat. Ord. Plantagineæ).—Perennial, with a short, branched root-

stock. Leaves downy, marked with five or seven ribs, no leaf stalks, arranged in a rosette lying close to the ground. Flowers in a short, dense spike, silvery green, with pink stamens. When it occurs on lawns all the vegetation under the leaves is destroyed. Flowers June to October. Height may reach 8 ins.

MEANS OF CONTROL.—*On Lawns.* —See DAISY.

On Paths.—See ANNUAL MEADOW GRASS.

USES.—See GREATER PLANTAIN.

Horsetail (*Equisetum arvense.* Nat. Ord. Equisetaceæ).—A leafless perennial, spreading by underground stems. Aerial stems are hollow, jointed, and brittle, with a sheath at each joint from which ten or twelve branches spring. Fruiting stems are unbranched and appear in the spring, being succeeded by the branched barren stems.

MEANS OF CONTROL.—See BINDWEED.

USES. — Plant contains many coarse particles and is very useful for polishing tin vessels, hard woods, brass, etc. This species, among others, has been much used by dairymaids in the North of England for polishing their milk pails. An allied species has been imported from Holland under the name of DUTCH RUSHES.

Knot-grass (*Polygonum aviculare.* Nat. Ord. Polygonaceæ).—Annual, creeping. Stems much branched and wiry. Leaves small and simple. Flowers pink or red, in tiny clusters at the bases of the leaf stalks. Fruits triangular, black. Flowers May to October.

MEANS OF CONTROL.—Constant hoeing.

USES.—Pigs are fond of Knot-grass, and it is often made into hay in Alsace. In Japan a blue dye resembling indigo is manufactured from this plant.

Meadow Grass. — See ANNUAL MEADOW GRASS.

Moss.—This name is given to a group of small plants varying in height from half an inch upwards, which consist of a fine stem and delicate green leaves but do not bear flowers or seeds. Instead of these a fruiting capsule is produced, containing a large number of tiny spores, which are scattered by the wind, and spread the plant from place to place.

MEANS OF CONTROL.—The presence of moss on lawns usually indicates bad drainage or poverty of soil. A mossy lawn should be well raked to remove as much moss as possible, and should then be dressed with a mixture of one part of lime to four parts of soil, together with a little artificial manure. The lawn should be kept well rolled. Good results have been obtained by first watering with a 5 per cent. solution of sulphate of iron, and then sprinkling frequently with a weak (3 per cent.) solution of nitrate of soda.

Nettle.—See RED DEADNETTLE and STINGING NETTLE.

Nightshade.—See BLACK NIGHTSHADE and ENCHANTER'S NIGHTSHADE.

Orache.—See COMMON ORACHE.

Persicaria (*Polygonum persicaria.* Nat. Ord. Polygonaceæ).—Annual. Stem branched. Leaves long and narrow, usually with a dark spot in the middle. There is a fringed membranous sheath round the stem at each joint, formed by the stipules or appendages to the leaves. Flowers pale pink or red, in rather dense clusters. Upper part of the plant often turns red. Flowers summer and autumn. Height, 1–2 ft.

MEANS OF CONTROL.—Constant hoeing.

Petty Spurge (*Euphorbia Peplus.* Nat. Ord. Euphorbiaceæ).—A low-growing annual, repeatedly branched

from the base. Leaves small, simple, and alternate, without leaf stalks. A forked, three-rayed umbel of greenish flowers occurs at the end of almost every branch. Fruit a three-seeded capsule. Whole plant contains a milky juice. Flowers summer and autumn. Height, 1 ft.

MEANS OF CONTROL.—Constant hoeing.

Pimpernel.—See SCARLET PIMPERNEL.

Plantain.—See GREATER PLANTAIN, HOARY PLANTAIN, and RIBWORT PLANTAIN.

Red Deadnettle (*Lamium purpureum.* Nat. Ord. Labiatæ).—Annual. Stems square. Leaves stalked, heart-shaped, toothed, and opposite. Flowers in whorls at the base of the upper leaf stalks, reddish-purple, hooded. Fruits plentiful, four nutlets being formed from each flower. Flowers April to October. Height, about 1 ft.

MEANS OF CONTROL.—Constant hoeing.

Ribwort Plantain (*Plantago lanceolata.* Nat. Ord. Plantagineæ).—Perennial, with a short, thick, and branched rootstalk. Leaves long and narrow, with three or five ribs, arranged in a rather erect rosette. Flower stalks long, bearing a short, close head of greenish flowers. Fruits two-seeded. Flowers spring to autumn. Height may reach 1 ft.

MEANS OF CONTROL.—*On Lawns.*—See DAISY.

On Paths.—See ANNUAL MEADOW GRASS.

USES.—The seeds of various kinds of plantain are surrounded by mucilage, which is used for stiffening muslin.

Scarlet Pimpernel (*Anagallis arvensis.* Nat. Ord. Primulaceæ).—Annual. A much-branched trailing plant with smooth, opposite leaves and bright scarlet flowers which close at the approach of rain (hence the name POOR MAN'S WEATHER GLASS). Seed vessels open by a circular cap; seeds numerous. Flowers May to October.

MEANS OF CONTROL.—Constant hoeing.

Shepherd's Purse (*Capsella Bursa-pastoris.* Nat. Ord. Cruciferæ).—Annual. Leaves more or less cut up, very variable in shape, arranged in a rosette, from the middle of which arises a flowering stalk bearing numerous insignificant white flowers. Fruits heart shaped, splitting into two boat-like pieces to allow the numerous seeds to escape. Flowers practically all the year round. Height about 1 ft.

MEANS OF CONTROL.—Constant hoeing and hand weeding.

USES.—Was originally boiled and eaten as greens, and in some parts of North America it has been sold in the markets for this purpose.

Sow-thistle.—See COMMON SOW-THISTLE.

Spurge.—See PETTY SPURGE and SUN SPURGE.

Stinging Nettle (*Urtica dioica.* Nat. Ord. Urticaceæ).—Perennial, with creeping underground stems. Leaves opposite, simple, and deeply toothed. Flowers inconspicuous, greenish, in drooping tassels at the bases of the upper leaf stalks. Pollen and seeds are usually borne on different plants. Seed abundant. Whole plant is covered with stinging hairs. Flowers summer and autumn. Height, 2–3 ft.

MEANS OF CONTROL.—See BINDWEED.

USES.—A most valuable plant. The fibrous stems are converted into cordage, fishing-lines, and even textile fabrics and sewing thread. A decoction of nettles and common salt makes a good rennet for coagulating milk. The young tops are boiled and eaten as spinach, and the

chopped-up leaves are said to encourage egg laying if they are fed to fowls. In Sweden nettles are cultivated as fodder for farm animals, which eat them readily when dried. A dye is obtained from the roots, which gives a yellow colour to wool when boiled with alum.

Sun Spurge (*Euphorbia helioscopia*. Nat. Ord. Euphorbiaceæ).—Annual. Little branched. Leaves alternate, simple, notched at the edge, rounded at the tip. Flowers golden-green, in a flat, five-rayed umbel at the top of the stem. Fruit a three-seeded capsule. Whole plant contains a milky juice. Flowers the whole season. Height, 6–12 ins.

MEANS OF CONTROL.—Constant hoeing.

USES.—Is used for removing warts. It is said to cure toothache if the juice be rubbed on the skin behind the ear.

Thistle. — See COMMON SOW-THISTLE and CREEPING THISTLE.

Twitch or **Twitch-Grass.**—These names are often applied to BENT GRASS and COUCH GRASS, which see.

In addition to the weeds described above, various other kinds may occasionally be met with as garden weeds, and in certain cases, under specially favourable circumstances, an unusual weed may be exceedingly troublesome.

As a general rule the plants should be prevented from forming seed by constant hoeing. Annual weeds can be easily kept down in this way; but with perennial plants as much as possible of the underground stem or root system should be removed by digging or trenching, as they spread more readily by vegetative reproduction than by seed formation.—W. E. B.

[It should be noted that the English and Botanical names in the above article are those in general use, and do not necessarily conform to the newer nomenclature adopted at Kew.—EDITOR.]

WEEDS AND WEEDING.

When Chickweed chokes our flowers
and plants,
And Nightshade over food crops
pants,
The gardener must use his hand,
And pull these weeds from out the
land.

When Dandelion thrives and blooms,
And Bindweed over all else looms,
With Couchgrass, Nettles holding
sway,
We need a fork, and that to-day.

Where Creeping Buttercup is seen,
We have to fork to keep land clean.
The same with that Convolvulus,
We dig it up with little fuss.

Fat Hen comes up quite quick by
hand,
And so does Groundsel from the
land.
Not so the Greater Bindweed, or
The Horsetail weed we often saw.

The last two weeds are terrors true,
At least to me, and you will rue
If they are left to romp about,
When every scrap should be dug out.

The Pimpernel and Shepherd's Purse—
These weeds are very little curse—
Are easily pulled up by hand,
Especially if soil be sand.

The Thistles—truly awful weeds,
Don't speak to me of Thistles' seeds—
Need scything down before they
bloom,
And burning is, of course, their doom.

The Sun Spurge, but a lowly plant,
Is not the subject for much cant;
The same applies to Celandine:
They decompose to humus fine.

A naughty weed is Stinging Nettle,
It stings to show its own high mettle.
We glove our hands, or grasp it tight,
And jerk its roots out to the light.

And there are many other weeds,
Too many for the gard'ner's needs.
Some weeds are terrors, some are not,
But all on neatness form a blot.

And ev'ry weed where'er it lie,
A robber is of blackest dye.
A fact, but seldom recognised,
Which often makes me quite surprised.

Then let us each with hand and hoe,
Or fork or spade, move down each row,
And knock the weeds up with a will,
Then quickly our big barrow fill.

The weeds with long tap-roots or seed
Must burn to ash, our plants to feed.
All others in a hole may rot
To give us humus pure and hot.

WEIGHTS AND MEASURES.

Although it is perhaps natural that every trade and profession should have methods of computation peculiar to itself, it is doubtful if there is one in which such a variety exists as in horticulture. Technical terms are, of course, inseparable from any particular industry, but one would think that in the twentieth century some attempt should be made to standardise as much as possible all commodities that are sold by weight or measure. Apart from the "tricks" that are in all trades (except our own), it would be a great convenience if standard weights and measures could be established for the sale of fruits and vegetables, seeds, and perhaps manures and certain classes of sundries. So far as flowers and many kinds of vegetables are concerned it may be impossible to establish anything approaching a standard, as the articles are so varied in nature and in bulk. For example, take the term "bunch." It is used in every conceivable way and for a great variety of saleable stuff, but can any one define what a "bunch" is? The difficulty will be at once apparent when one mentions a bunch of, say, carnations, forget-me-nots, gypsophila, lilies-of-the-valley, carrots, onions, radishes, turnips, etc. Again, take the well-known term "bundle." Look at the difference between a "bundle" of rhubarb in January and a bundle of rhubarb in May. One is vastly bigger than the other. The terms "bunch" and "bundle" are, therefore, undefinable in practice. At the same time, everyone who sells flowers or vegetables in bunches or bundles knows very well just about how large or how small a bunch of any particular subject has to be to secure a ready sale in the market.

But even when we come to recognise measures that are supposed to be "standard" ones, we find totally different meanings attributed to them in different parts of the kingdom; or the same kinds of produce are sold in different ways, and in quite different measures. Some of these measures are well known in some parts of the country, but are quite unknown in other parts. Thus the "bushel" and "half-bushel"—also known as the "sieve" and "half-sieve"—is universally used in the London markets for measuring apples, gooseberries, pears, plums, etc. But in the midlands and northern markets the "pot" is the recognised standard of measure for similar articles, while in Glasgow and the West of Scotland the "sleek" becomes the measure. In London, raspberries (except when sold to jam manufacturers) are offered in "punnets," but in other places in "gallons" or "pecks." Tomatoes are sold in "strikes" holding 12 lb. nett, but are also sold in pecks or other measures in different weights. Strawberries are sent to market in "chip" baskets supposed to hold 4 lb. nett, but the "nett," as often as not, includes the weight of the basket. Mushrooms are sold in punnets holding 1 lb., also in "strikes" or peck baskets. Mustard and cress (the well-known "hot and cold" of the market) is always sold in punnets, but there is no comparison beyond the name between the mustard and cress "punnet" and the "punnet" in which seakale is sold.

Taking the larger vegetables and salads, cabbages, etc., are sold by the "tally"—a measure meaning five dozen. Cabbages as "greens," however, are sold in bushels or boxes, while cauliflowers may be sold by the tally, and in "crates," or other measures holding a definite number. Lettuces

are sold by the score, but a "score" of lettuces numbers 22 and not 20. The same applies to endive. Spinach is sold by the bushel, but there is no recognised weight, so much depending upon the method of packing. The same applies to sorrel, and one must be careful not to secure a good weight at the cost of sadly bruising the tender leaves. Rhubarb is sold in bundles, as already mentioned, but there is no recognised number of "sticks" or stalks to the bundles. Celery is sold in "rolls" which may contain six, eight, or twelve "heads" or plants. Radishes, turnips, leeks, and carrots are sold in "bunches," but the number of roots to a bunch varies considerably with the period of the year and the ruling prices. Carrots are also sold by the "bag" weighing perhaps a cwt. or more, but they are also sold by the bushel or half-bushel, and other measures in different localities. The same applies to parsnips and often to beetroot. The last named is, however, an article by itself, as it is often sent to market already cooked, and is then sold by number. Potatoes are sold in sacks containing 1 cwt. (dirt and all), but also by the bushel, half-bushel, peck, gallon, quarter,[1] pottle, or pound when retailed. Jerusalem artichokes are usually sold in half-bushels holding about 28 lb., and brussels sprouts are sold in the same way, but only about 15 or 16 lb. go to the half-bushel well heaped up.

It will thus be seen from what has been outlined above that to attempt anything like "standardisation" of weights and measures for horticultural produce is by no means a light task. What might be done with advantage in many cases would be to sell by "weight" when possible and not by "measure." Everyone understands the exact meaning of a pound, a cwt., and a ton. But when bushels, sieves, pots, strikes, bundles, etc., are used, the weight may be anything at all according to the nature of the goods. There is of course nothing unfair in using these measures, but care should be taken to see that they should all be of standard size, and not of different sizes, some larger or smaller than others.

[1] This "quarter" is a quarter of a peck, not a quarter of a cwt. It is a measure never heard of in the south of England.—EDITOR.

If a man buys 1000 bushels of apples or 1000 half-bushels of plums or cherries, he naturally expects that each measure holds approximately the same weight. That, however, only appertains if the article is also the same variety. It is well known that all apples are not of the same weight or solidity. A bushel of one variety, therefore, will weigh more or less than a bushel of another variety. But with this reservation similar measures of any one variety of fruit should contain about the same weight.

Fertilisers, Manures, and Soils.—Much confusion often arises as to what is meant by bushels of soil, fertilisers, or manures. The directions to add so many bushels of this or that to a ton of soil, or conversely to add so much fertiliser to so many bushels of soil, are constantly occurring in the press, but as far as we are aware no list of weights of these common materials has ever been published. It has thus been thought useful to determine by actual experiment the approximate weights of a number of these materials, and although, of course, incomplete, the list which follows covers, we think, the majority of materials that the amateur is likely to handle. Here it should be remembered that 8 gallons go to a bushel, and 4 pecks one bushel, so that these equivalents can easily be found if wanted, though it would be waste of space to give separate columns to them in this work. The weights given are, of course, approximate; the actual weights depending so much on the amount of moisture in the materials at the time of weighing.

TABLE OF WEIGHTS OF BUSHELS, OF FERTILISERS, MANURES, AND SOILS.

Material.	Weight of Bushel, lb.
Alum	84
Bacterised Peat	29
Basic Slag	80–100
Black Leather Dust	28
Black Sulphur	82
Blue Vitriol	100
Bone Dust or Flour	56
Bone Phosphate	144
Bonemeal	56
Bones, Burnt	89
Building Sand	132
Calcined Magnesia	15
Carbonate of Magnesia (Heavy)	40
Carbonate of Magnesia (Light)	12
Carbonate of Soda (Crystallised)	64
Catch Pit Refuse (Dried)	54

Material.	Weight of Bushel, lb.
Chalk (Ground)	100
Chalk (Lump)	96
Cinder Ashes	40
Copper Sulphate	100
Desiccated Fish Guano	55
Dried Tank Sewage Sludge	40
Epsom Salts	82
Fish Guano	40–50
Fish Manure	50–56
Flour of Sulphur	78
Flue Dust	40–50
Fresh Pressed Sludge Cake	48
Gaslime	56
Glaubers Salts	72
Green Vitriol	68
Ground Chalk	100
Ground Lime	56
Guano	50–56
Guano, Fish	40–50
Guano, Ichthemic	62
Guano, Native	40–66
Gypsum	60
Heavy Carbonate of Magnesia	40
Horn Dust	10
Horn Shavings	9
Iron Sulphate	68
Ivory Dust	45
Kainit	56–60
Leaf-mould	46
Leather Dust (Black)	28
Leather Dust (Red)	20
Light Carbonate of Magnesia	12
Lime	56
Limestone	106
Loam	72
Maiden Loam	60–70
Muriate of Potash	56–60
Nitrate of Lime	80
Nitrate of Potash	56–60
Nitrate of Soda	56–60
Nitrolim or Nitrolime	80
Old Sewage Sludge Cake	64
Peat	76
Phosphate of Lime	92
Phosphate of Potash	82
Phosphate of Soda	68
Pigeon Manure	66
Potting Loam	74
Poultry Manure	66
Pressed Sewage Sludge (Fresh)	48
Pressed Sewage Sludge (Dried)	38
Proprietary Fertilisers	56–72
Quicklime	80
Red Leather Dust	20
Roll Sulphur	99
Salt	65
Saltpetre	96
Sand, Building	132
Sand, Silver	130
Seaweed	40
Shoddy	18
Slaked Lime	74
Sludge Cake	48
Soot	25–30
Spent Hops	40
Sulphate of Ammonia	57
Sulphate of Iron	68
Sulphate of Lime	60
Sulphate of Magnesia	82
Sulphate of Potash	120
Sulphate of Soda	72
Sulphur, Black	82
Sulphur, Yellow	78
Superphosphate of Lime	56–62
Tank Sludge (Dried)	40
Tricalcium Phosphate	92
Vegetable Humus	46
Washing Soda	60
Wood Ashes	40–50

Fruit.—The following tabulation will give some idea of the variation in weight of a "bushel" or half-bushel of fruit, the figures given being approximate as tested in most cases by actual weighing.

TABLE OF FRUIT MEASURES WITH THEIR EQUIVALENT WEIGHTS.

Fruit.	Bushel or Sieve.	Half-Bushel or Half-Sieve.
Apples	40–45 lb.	20–22 lb.
Cherries	36–40 ,,	18–22 ,,
Gooseberries	40–48 ,,	20–24 ,,
Pears	56–60 ,,	28–30 ,,
Plums	48–52 ,,	24–26 ,,

Vegetables.—In the following table the weights of measured quantities of Vegetables are given, which will again show great variation. The cwt. of any vegetable is always 112 lb., so a column devoted to that is unnecessary. It should, however, be specially noted that the "Quarter" mentioned in the case of Vegetables is not the same as the "Quarter" for Manures. That for Vegetables is a quarter of a peck, and that for Manures is a quarter of a cwt. It must also be noticed that a peck, though by some regarded as the same as a stone, is by no means always equal to it in weight owing to the difference in the articles weighed.

[TABLE

TABLE OF VEGETABLE MEASURES WITH THEIR EQUIVALENTS.

Vegetable.	Weight of Bushel.	Weight of Peck.	Weight of Stone.	Weight of Quarter.

,, Seed	56–60	14 –15	14	3½

[1] In some cases, as will be seen, the peck is approximately half a stone, and the quarter a quarter of a stone, but this is the exception rather than the rule.—EDITOR.

[2] Here the weight of the peck is approximately two stones or a quarter of a cwt., and the quarter is approximately half a stone.—EDITOR.

[3] This is another case of the absurdity of our Weights and Measures. To have a difference of 7 lb. between pecks of different kinds of potatoes provides food for mirth and ridicule to many foreign countries.—EDITOR.

Water Measures.—If the previous tables contain many strange differences, the water measures contain more, and it is a problem too difficult for us to answer why a hogshead of water should not contain as many gallons as a hogshead, say, of methylated spirits. Again, the terms barrel, cask, and hogshead are at times considered synonymous, but they all contain a different number of gallons. It seems childish to measure spirit in one way and water in another, but it is done. Again, grave confusion arises on account of the Noggin or Gill being considered to contain half a pint instead of a quarter.

The table above is useful for estimating the weight of any quantity, say, a gallon of soot. Weigh a pint, multiply by 8 and you have it.

Miscellaneous Measures. — Besides the water measures there are others. For instance, there are two DRY MEASURES—one for measuring coal, and one for corn and seeds. That used for corn and seeds is also used for measuring manures and fertilisers, but at times the other is used, so confusion arises. The IMPERIAL HEAPED MEASURE, as the one for coal is called, has 8 gallons in each bushel, 3 bushels to a sack, and 12 sacks to the chaldron. The following table shows the various equivalents of the dry measure. Great care must be taken not to confuse "one load" with "one ton," as they are often quite different,[2] the former may contain over 1000 lb. more than the latter.

The table below will prove a

TABLE OF WATER MEASURES WITH WEIGHTS IN POUNDS.
(Two Glasses = One Noggin or Gill; Four Gills = One Pint.)

Pints.	Quarts.	Gallons.	Barrels.	Casks.	Hogsheads.	Weight of Water in lb.

512	256	128	64	32	8	1	1/5	640
2560	1280	640	320	160	40	5	1	3200

[1] One hogshead of spirits, or indeed any other liquid save water (and beer), contains 63 gallons, while casks and barrels are of many capacities.—EDITOR.

[2] The weight of a cartload of anything varies between wide limits. A cartload of feathers would weigh very little. A cartload of flue dust weighs 12–15 cwt., while one of sand will weigh about 22–25 cwt. The "load" in our table is from the Imperial Corn Measure by which eating potatoes are measured in some parts of the country. The weight of a load of these is 3360 lb., not 2240 lb. as in a ton.—EDITOR.

ready means of ascertaining the weights of any bulk quantities of fertilisers which may not be in our previous table. Thus, for instance, if the gardener is instructed to apply a bushel of a certain fertiliser, and he has not got a bushel measure, all he need do is carefully to weigh a pint, multiply the result by 64, and he has got what he requires. He can then proceed to weigh out the fertiliser instead of having to measure a pint out 64 times. A way of quickly finding the weight of a bushel may also be useful: First estimate the number of ounces in a pint of the material, multiply by four, and call the result pounds instead of ounces, and it will be the weight in pounds of a bushel of the material.

LINEAL MEASURE. — Having disposed of measures of capacity, we now come to measures of length. Here, again, as many gardeners know to their cost, calculations are made as difficult as they can be owing to our awkward constants. Every gardener, of course, knows that 12 ins. make one foot, and 3 ft. one yard, but where fathoms, leagues, links, etc., and such like are spoken of many are "at sea." The following table shows the relations of all lineal measures one to another:—

TABLE SHOWING AT A GLANCE RELATIONS OF LINEAL MEASURES TO EACH OTHER.

Inches.	Hands.	Links.	Feet.	Yards.	Fathoms.	Poles.	Chains.	Furlongs.	Miles.	Leagues.
1	$\frac{1}{4}$	$\frac{1}{8}$	$\frac{1}{12}$	$\frac{1}{36}$	$\frac{1}{72}$	..	..	..	..	..
4	1	$\frac{1}{2}$	$\frac{1}{3}$	$\frac{1}{9}$	$\frac{1}{18}$	..	..	..	..	..
8	2	1[1]	$\frac{2}{3}$	$\frac{2}{9}$	$\frac{1}{9}$	..	..	..	..	..
12	3	$1\frac{1}{2}$	1	$\frac{1}{3}$	$\frac{1}{6}$	..	..	..	..	..
36	9	$4\frac{1}{2}$	3	1	$\frac{1}{2}$	..	..	..	..	..
72	18	9	6	2	1	..	..	..	..	..
198	$49\frac{1}{2}$	$24\frac{3}{4}$	$16\frac{1}{2}$	$5\frac{1}{2}$	$2\frac{3}{4}$	1	..	..	..	..
800	200	100	66	22	11	4	1	..	..	..

..	..	..	15840	5280	2640	960	240	24	3	1

MEASUREMENTS OF AREA.—We now come to measures of area. These are by no means as simple as they might be, but the following table shows the relation of one to another, the largest and most awkward numbers being purposely omitted:—

TABLE SHOWING AT A GLANCE RELATION OF SQUARE MEASURES TO EACH OTHER.

Square Inches.	Square Links.	Square Feet.	Square Yards.	Square Poles.	Square Chains.	Square Roods.	Acres.
$62\frac{1}{4}$ nearly	1	..	..	..	..	..	..
144	$2\frac{1}{3}$ nearly	1	..	..	..	..	..
1,296	$20\frac{2}{3}$ nearly	9	1	..	..	..	..
39,204	625	$272\frac{1}{4}$	$30\frac{1}{4}$	1	..	..	..
..	10,000	4,356	484	16	1	..	..
..	..	10,890	1210	40	$2\frac{1}{2}$	1	..
..	..	..	4840	160	10	4	1

[1] For all practical purposes one link may be taken as 8 ins.—EDITOR.

SOLID MEASUREMENT. — It often happens that gardeners want to know the equivalents of bushels, gallons, etc., in cubic feet. As far as we are aware no such data has yet been published in works of gardening reference, and in books on mathematics it is usually put in too obscure a manner to be easily understood. The following table, however, will clearly show the relation of these one to another.

WEIGHTS AND AREAS. — Another matter on which the gardener often wants information is that of transferring ounces per square yard into cwts. per acre. Here the inconvenience

TABLE OF EQUIVALENTS OF CAPACITY MEASURES WITH SOLID MEASURES.

Cubic Inches.	Quarts.	Gallons.	Pecks.	Cubic Feet.	Bushels.	Barrels.	Casks.	Hogsheads.	Quarters.	Cubic Yards.

48	91	1536	13 5/7	34 2/7	140	7
50	94	1600	14 2/7	42 6/7	150	7 1/2

of our present system is shown up more than in any other case. There are, as is well known, 16 ounces to each lb., 14 lb. to the stone, 28 lb. to the quarter, and 112 lb. to the cwt., but these bear no relation to the fractions of an acre. We saw in a previous table, that 30¼ sq. yds. were equal to a sq. pole, perch or rod, that 40 poles equalled one rood, and that 4 roods were one acre. An acre, we found, was 4840 sq. yds. As there is no relation evident from the above, we have worked them out and give them in the table on p. 1182.

WILD GARDENING.

The term "Wild Garden" is applied to the placing of hardy plants in places where they will take care of themselves. It does not mean the picturesque garden, for a garden may be picturesque and yet in every part the result of ceaseless care. What it does mean is best explained by the Winter Aconite flowering under a grove of naked trees in February; by the Snowflake abundant in meadows by the Thames; and by the Apennine Anemone staining an English grove blue. I wish the idea to be kept distinct from the various important phases of hardy plant growth in groups, beds, and borders, in which good culture may produce many happy effects; from the rock garden or borders reserved for choice hardy flowers; from growing hardy plants of fine form; and from the ordinary types of spring garden. In the smaller class of garden there may be little room for the wild garden; but in the larger gardens, where there is often ample room on the outer fringes of the lawn, in grove, park, copse, or by woodland walks or drives, beautiful effects may be created by its means.

Many hardy flowers will thrive better in rough places than ever they did in the old mixed border. Even small ones, such as the Ivy-leaved Cyclamen, are naturalised and spread all over the mossy surface of the woods. In consequence of plant, fern and flower, with climber, grass and trailing shrub, relieving each other, they will look better than in stiff gardens. No ugly effects will result from decay and the swift passage of the seasons; it will enable us to grow many plants that have never yet obtained a place in our "trim gardens"—multitudes that are not showy enough for a place in the flower-garden. Among the plants often thought unfit for garden cultivation are a number, such as the Asters and Golden Rods (*Solidago*), which overrun the choicer border-flowers when planted among them. To these might be added plants like the Winter Heliotrope, and many others which, while interesting in the flower garden, are apt to spread so rapidly as to become a nuisance.

In this way we may settle the question of spring flowers, as well as that of hardy flowers generally; and many parts of the grounds may be made alive with spring flowers, without in the least interfering with the flower garden itself. An example or two of what has already been done with Daffodils may serve to show the way and explain the gains of the wild garden, and there is no more charming flower to begin with than the Narcissus, which, while fair in form as any

orchid or lily of the tropics, is as much at home in our climate as the kingcups in the marsh and the primroses in the wood. And when the wild Narcissus comes with these, in the woods and orchards of Northern France and Southern England, it has also for companions the violet and the cowslip, hardiest children of the north, blooming in and near the stiff, leafless woods. This fact should lead us to see that it is not only a garden flower we have here, but one which may give much beauty to our woods and fields or meadows as well as to the pleasure grounds. In our country in many places there is room to grow them in other ways than in the garden proper, and this is not merely in country seats, but in orchards and cool copses, and by woodland rides. To chance growth in such places, we owe it already that many Narcissi or Daffodils, which were lost to gardens in the period when hardy plants were wholly set aside for bedding plants, have been preserved to us, at first probably in many cases thrown out with the garden refuse. In many places in Ireland and the West of England, Narcissi lost to gardens have been found in old orchards and meadows.

There are many gardens in the kingdom which are disfigured by vain attempts to grow trees, shrubs, and flowers that are not really hardy, and it would often be much wiser to devote attention to things that are absolutely hardy in our country, like most Narcissi, to which the severest winters make no difference; and we know from their distribution in Nature how fearless they are in this respect. Three months after our native kind has flowered in the weald of Sussex and in the woods or orchards of Normandy, many of its allies are beneath the snow in the mountain valleys of Europe, waiting till the summer melts the deep snow. Soils which are cool and stiff and not favourable to a great variety of plants, suit Narcissi perfectly. On the cool mountain marshes and pastures, where the snow lies deep, the plant has abundance of moisture —one reason why it succeeds better in our cool soils. In any case it does so, and it is mostly in dry, light soils that Narcissi fail.

At the same time we may be mistaken as to failures which now and then arise from other causes than the soil. I planted, years ago, some Bayonne Daffodils on the northern slopes of a poor field, and thought the plants had perished, as so little was seen of them after the first year. Despairing of the slope, it was planted with Alder, a tree which grows in any cool soil. Years afterwards, walking through the Alder, I found the Bayonne Daffodil in perfect bloom.

As to the kinds we may naturalise with advantage, they are almost without limit, but generally it is better to take the groups of Star Narcissi, the Poets, and the native Daffodil, of which there are so many varieties. We can be sure that these are hardy in our soils, and, moreover, as we have to do this work in a bold way, we must deal with kinds that are easiest to purchase.

There is hardly any limit except the one of rarity, and we must for the most part put our rare kinds in good garden ground till they increase, though we have to count with the fact that in some cases Narcissi that will not thrive in a garden will do so in the grass of a garden or orchard. The fine distinct effect of Narcissi in groups in the grass should not be forgotten. It is not only their effect near at

hand that charms us, but as we walk about we may see them in the distance in varying lights, sometimes through and beyond the leafless woods. And there is nothing we have to fear in this charming work save the common sin of overdoing. To scatter Narcissi equally over the grass everywhere is to destroy all chance of repose, of relief, and of seeing them in the ways in which they often arrange themselves. It is almost as easy to plant in pretty ways as in ugly.

How to Plant.—I usually plant Narcissi in grass by turning back the sod, making two cuts with the spade at right angles, and then pressing the sod up and back, laying it back on a hinge, as it were, putting in a few bulbs, mostly round the sides of the hole, turning the sod back, and treading firmly upon it. The question is largely one of convenience and the ground one has to plant. If one could improve the subsoil it would be better for some soils, no doubt, but if the work is done in a bold way and there is much other planting going on, it is not easy to get time to plant things in the grass with care. Sometimes, in breaking new ground or carrying out changes, one gets a chance of throwing in some bulbs before the surface is levelled up. Once, in planting Grape Hyacinths in an uneven grassy slope, they were placed on the turf in the hollows, and then levelled up with earth, and both grass and bulbs soon came through. In certain soils seeds may be sown betimes—seeds of Foxglove, Evening Primrose, and stout biennials. Fragile bulbs will want more care, and less depth than the bolder Narcissi. All planting in the grass should be in natural groups or prettily fringed colonies, growing to and fro as they like after planting. Lessons in this grouping are to be had in the woods, copses, heaths, and meadows, by those who look about them as they go. At first many will find it difficult to get off formal masses, but they may be got over by studying natural grouping of wild flowers. Once established, the plants soon begin to group themselves in pretty ways.

The Soil.—In the cultivation of hardy plants, and especially in wild gardening, the important thing is to find out what subjects really do in the soil, without which much good way cannot be made. Many people make errors in planting things that are tender in our country, and very often fail in consequence; but apart from such risky planting, perfectly hardy plants may disappear, owing to some dislike of the soil. They flower feebly at first and afterwards gradually wane, in spite of all our efforts. I have made attempts to establish spring Snowflakes (*Leucojum vernum*) in grass, none of which succeeded, owing to the cold soil, yet one of the Snowflakes in the Thames Valley grows with the vigour of a wild plant. The Narcissus, which is so free and enduring in cool, damp soil, does little good on warm, light, or chalky soil. What will do or not do is often a question of experience; and the point is, when we see a plant doing well in soil like our own, to take the hint.

People often complain of the texture of the grass as a cause of failure, yet I have thousands of the Tenby Daffodil, and have had them for ten years, in rich and rank masses of Cocksfoot and other coarse grasses in coverts never mown or the old grass taken away at any time, and the Narcissus gets better year by year. So it is a question of finding out the plant the soil will grow. Some things are so omnivorous in their appetites that they will grow

anywhere; but some, the more beautiful races of bulbous and other early flowers, will only thrive and stay with us where they like the soil. It should be clearly seen, therefore, that what may be done with any good result in the wild garden cannot be determined beforehand, but must depend on the nature of the soil and other circumstances, which can be known only to those who study the ground.

Flowers Beneath Trees.—Where the branches of trees, both evergreen and summer-leafing, sweep the turf in pleasure-grounds, many pretty spring-flowering bulbs may be naturalised beneath the branches, and will thrive without attention. It is chiefly in the case of deciduous trees that this can be done; but even in the case of Conifers and evergreens, some graceful objects may be dotted beneath the outermost points of their lower branches. We know that a great number of our spring flowers and hardy bulbs mature their foliage and go to rest early in the year. In spring they require light and sun, which they obtain abundantly under the summer-leafing tree; they have time to flower, and grow under it before the foliage of the tree appears. Then, as the summer heats approach they are overshadowed, and go to rest; but the leaves of the trees once fallen, they soon begin to reappear and cover the ground with beauty.

WINDOW GARDENING.

The cultivation of a few plants in a sunny window appeals to almost everyone, but more particularly those having no greenhouse; and although the number of really choice plants which could be relied upon to pass through a severe winter in an ordinary living-room without fire-heat through the night is necessarily somewhat limited, with ordinary care a room may be kept bright at all seasons of the year.

Possibly the chief reason why so many window gardeners fail to get the full benefit either of flowers, or beautiful healthy looking foliage, is owing to the fact that they will insist upon following a set rule for watering, instead of giving this only when the plant really is in need of it, the result being that a plant which at the time of its introduction to the window was to all intents and appearances a perfect specimen, soon becomes sickly in appearance, a welcome prey to insects, and if not taken in hand by others having more experience comes to an untimely end.

Certain people fail to maintain their window plants in a healthy condition by giving water only in a spasmodic way, which when dealing with the majority of plants can have but one end—stunted growth, and early loss of beauty, if not actual death.

But perhaps the plan most generally followed by the more timid class of window gardeners is, to act upon the little-and-often principle, which perhaps is the least desirable of all.

If window gardening is to be a success, the plants should be given into the care of one person only. It is when all members of the household are interested, but no one directly responsible, that the most disastrous results follow; but where the person in charge of these is really interested, and tries hard to keep the plants in health throughout the year, there is no reason why most of the plants mentioned below should not be equally as attractive when grown in the window ledge, or in the case of some stood on a stool some little distance away from the window, as others grown in a cool greenhouse or conservatory.

As a guide to watering, we may at once say, no hard-and-fast rules can be laid down; the temperature of the room and the number of the roots made by the plant very largely determine this, but the observance of the few hints below will largely help to keep the plants in a healthy state.

When potting, always leave a good margin for water.

Allow ample drainage, and keep the bottom hole open.

Pot very firmly, leaving the surface level.

Never use soil for potting which is dust dry.

Never use soil in a sodden condition.

When re-potting, if the soil is dry, give a good watering an hour before.

Always bury the stems of the plant a trifle deeper than before.

Should a plant get dust dry, stand in a pail of water for a quarter of an hour.

Should a plant have an overdose of water and show signs of distress, stand away from bright sun for a few days.

When in doubt, don't water. It is far easier to bring a half-starved plant back again to a healthy state than one persistently over-watered.

Do not give stimulants of any kind to a plant until the pot is well filled with roots, and in the case of flowering plants, discontinue to give

manures after the flowers begin to open.

A good general soil for window plants is three parts good turfy loam, one part old manure, one part leaf-soil, and an eighth silver sand.

Always use clean pots, which should be thoroughly dry before filling, and when new ones have to be used, soak these in water for half an hour.

Window Gardening Plants : PLANTS EASILY RAISED FROM SEED. — *Agathaea coelestis*, Begonias, Calceolarias, Cinerarias, Cockscombs, *Francoa ramosa*, Mimulus, Petunias, Primulas, Solanums.

ORNAMENTAL PLANTS FROM SEED. —Acacia, *Aloysia citriodora*, Aralia, *Asparagus Sprengeri*, *Dracæna indivisa*, Eucalyptus.

PALMS.—*Cocos Wedelliana*, *Geonoma gracilis*, *Kentia Belmoreana*, *Kentia Forsteriana*, *Phœnix Ropicela*, *Phœnix reclinata*, and *Phœnix Robelini*. In addition to these there is quite a large family of Dracæna ; nearly all of what are termed cool greenhouse varieties will do equally well in an ordinary living-room where plenty of light and air reaches the plant.

The well-known *Aspidistra lurida variegata* is perhaps the most easily managed of all popular plants available for large windows, its nearest rival being the Asplenium, or Pteris Ferns, while of late years, *Araucaria excelsa* has made many friends among window gardeners. *Coronilla glauca* and *Diplacus glutinosus* make splendid specimens for a large window, while nearly all the more popular members of the Cactus tribe will flourish if not over-watered.

The above by no means exhausts the list of excellent material for window decoration ; in fact, where proper attention is given, many of the best known occupants of small greenhouses will flourish here.

In order that growth may be even, it is very desirable that plants intended as specimens be turned round occasionally, in order that growth may be the same on all sides.

During frosty weather the plants should be taken from the window as the fire declines, or, failing this, place several sheets of paper between the plants and the window.—F. R. C.

[Should the soil turn sour owing to over-watering, and re-potting be impossible, a good watering with lime-water will probably put matters right.—EDITOR.]

WINTER GARDEN, THE.

Every gardener is of the opinion that the winter is the dullest and idlest time of the whole year, many, especially amateurs, having said to the present writer, "Oh, there is nothing to do in the garden now, so it is no good going out into it." However, certain things must be done in the winter which cannot well be done at any other time; thus there is no need to be idle, and little occasion to be dull.

An amateur once told the writer a long story about the difficulties of winter gardening. He was one of the kind who wished to get his digging done before Christmas, and that year it appeared that the Clerk of the Weather had conspired against him, and all other gardeners and allotment-holders alike. Every day, so this amateur said, the Clerk sent either rain, snow, or hail. One night it blew his greenhouse down; the next night it blew his frame into the next garden; the following night it blew his cloches away and broke most of them against a stone wall, and then the Clerk of the Weather tried to blow his house down. He terminated his story by asking me how he could work under such great disadvantages? Of course, in cases of that kind, it is not possible to carry out the work one would wish, and as one sits at home hearing the wind and rain beat against the windows, or watching the snow fall thick and fast early in December, one's spirits are apt to sink at the prospect of the work not getting done by the time it should be done. The black earth which one picks up by the pound on one's boots, when working on allotments, or in small gardens during December, seems very far removed indeed from the lovely colour borders or useful vegetable plots of June, July, and August. However, when the wrath of Nature has abated, we can, at least, be ready to take advantage of those fine days that come, and get to work on the land.

Digging.—Naturally one's thoughts first turn to digging. We cannot get good results in either flower or vegetable gardening unless we thoroughly dig, delve, and manure the soil. Deep digging and early digging are of very great importance, and very few gardeners realise the necessity of doing the work really thoroughly. Trenching, too, is an operation which cannot be done except during the winter, and as this operation takes up a considerable time, the earlier it is started the better. Proper trenching will take at least a month, if an acre is to be done, on a light soil, and it will take very much longer if the soil is of a strong, heavy nature. Bastard trenching will take about a week or ten days less for the same area.

Applying Artificials. — Another matter of importance in the early winter is the application of certain artificial fertilisers which cannot well be put on the land at any other time, if the results are to be worth the dressing. Such artificials include Basic Slag, Calcium Cyanamide (though this last may also be used in the early spring), various salts of Magnesia, as well as Kainit, Bone Flour, Bonemeal, Bone Phosphate, Flue Dust, and Wood Ashes. It would be out of place to describe here the best purposes to which these artificials are applied, as these matters are fully dealt with in the earlier parts of this work.

Getting in Compost.—The winter is also the best time for getting in supplies of the various composts such as turf, and so on. There is no time to bother about obtaining these materials in the spring, and also there is no opportunity then with pressure of extra work, for the proper stacking of them. Readers should turn to our article on *Composts* for various notes on these matters. While one is getting in composts, supplies of manure should be obtained in addition to those required for immediately digging into the ground. Few gardeners realise the enormous increasing value of very old stable or cow manure for potting purposes, or for digging in round the roots of choice subjects in the herbaceous border.

Seed Lists.—The seed list should also be made out not later than the beginning of January, and usually this is no small matter. The various points in favour of one variety or another must be weighed up carefully, so as to be sure of getting that variety which is most suitable for any given purpose. Seed catalogues should be studied most carefully, almost every winter evening until the order has been sent, and the descriptions of the various flowers and vegetables should not be too seriously read unless the gardener only buys from the bigger firms. It is an open secret among horticulturists that these descriptions are often not accurate, and that a new variety with a glorious description, which is published in a catalogue, may be merely a well-known variety under another name. We need hardly add that gardeners should not put cost first, but they should buy the best seeds only, and be willing to pay a fair price for them, since cheap seeds are not usually satisfactory as regards germination.

Planning Next Year's Garden.—This is a most interesting and necessary job in the winter. Plant lists from specialists should be carefully studied, also the known varieties commended by the Royal Horticultural Society. Any notes which the gardener has made during the summer for future planting should be gone through, and care taken that no choice sort is missed. During the winter evenings we can work out the colours with more care than is possible in the busy spring planting time, and we need hardly say that carefully planned borders are much more likely to give pleasure to the gardener and his friends, than are borders in which the colours are mixed up anyhow. Here the making of, and the working to, a plan is strongly to be recommended in order that the colours may be correctly placed. When making a plan do not, however, keep strictly to what is known as "height sequence." Have a few bold subjects towards the front.

This by no means exhausts the work for the winter, but it covers the more important matters. Those gardeners with a greenhouse should turn up the section on Winter Management in the article on *Greenhouse: Management of.*

WOMEN GARDENERS.

In dealing with the subject of Gardening as a career for women, it would be a pleasure to dwell simply on the attractive side of the subject, if only because it affords such a broad field of interest and such endless opportunities for ability and skill. But to enjoy gardening as a hobby and to practise it as a profession are widely different things. The one presupposes a taste only : the other demands vocation—with all that the word implies.

And if the true gardener is born, she must certainly also be made—and by this we mean to imply thorough training, grafted on a healthy disregard to comfortable conditions and an unlimited capacity for hard work.

A foundation of capability being assumed, it is well to decide as to the probable branch of gardening which will best suit the individual to take up. To make a success of "Landscape Gardening"—the much-abused name must be employed until a better be found—a woman gardener should have the best sort of technical training for this difficult craft, plus an inborn feeling for colour, form, and line. She will be fortunate if an opportunity offers to enter an architect's office ; but failing this, as sound a knowledge as possible of mathematical drawing should be obtained, and every possible opportunity taken in the practice of Design.

It is in this matter of Design that the Horticultural Training Colleges need just now to look especially to the needs of their pupils. They have rightly given of late years a vast amount of attention to the importance of (literal) spade-work. But it is obvious that, beyond all which is included in this, any special talent that a woman possesses must not stand in danger of being overlooked. It is, of course, important that a woman should be able to carry out every practical operation in a garden, in case no other help is available, but it is equally important that she should be possessed of certain special *fortes,* without the exercise of which it is by no means clear as to why she should receive higher pay than a man. In a word, the woman gardener ought to be able to command good prices by reason of her unmistakable *value,* whether it be as organiser of a gardening business, as horticultural instructor, or as garden designer and consultant. And in the rôles of garden designer and consultant, her work may well be found in establishing that better tradition of which the newer English gardens stand so badly in need and which cannot fail to have its influence from the large estate down to the suburban strip of ground.

The College Course.—To come now to the consideration of practical training for the gardening profession, this should take up not less than two years or, better still, three, and be followed by continental travel if possible. Now that the war is over, a definite stand must be made against the "Short Course" worker, since she can be no expert, as she has not had

[1] *Viburnum cassinoides* of Kew.—EDITOR.

the time and opportunity to study her subject under varying conditions. A woman gardener deserving real success should first qualify by taking a thorough training in her craft—following upon the best type of High School education, in which drawing, science, and handicrafts have played a preparatory part.

Typical Training Centres.—It will be useful here to mention a few typical examples of gardening courses. Needless to say, other good training colleges exist in plenty; and the proper agencies to which to apply for information on the subject are the Central Bureau for Women's Employment and the Women's Farm and Garden Union—which latter is also the recognised society for representing the interests of both women farmers and women gardeners, and to which a social and residential Club for the benefit of members has been recently attached.

The Horticultural Department of University College, Reading, offers a careful and practical training on University lines, both in the manual work and in its scientific bearings. Students may enter either for the "Certificate," "Diploma," or "Diploma with Distinction" Course, of two and three years respectively.

At Swanley Horticultural College (Kent) and at Studley College (Warwickshire), a special feature has always been made of market work, for which the large area of ground and glasshouses give ample opportunity. The courses of instruction at Swanley and Studley extend normally over two and three years, and afford opportunities for specialising on the scientific side of gardening, in Nature Study with a view to teachers' training, in Colonial work, and in many other branches. Nature Study in relation to gardening is further represented at the School of Gardening at Clapham, near Worthing (Sussex).

The excellent exhibits frequently seen at shows are a recommendation of the market work and specialisation in intensive French gardening as practised at the Thatcham Fruit and Flower Farm at Newbury (Berks).

An intending woman gardener whose home is in Ireland will be fortunate if she be one of those allowed the privilege of receiving a training in return for her services at the Royal Botanic Gardens, Glasnevin, Dublin. In Wales, the chief centre of gardening training is at Aberystwyth. This is in connection with the University.

For a girl who can live in or near London and to whom it is convenient to attend daily, rather than to reside in College, the Royal Botanic Society's Practical Gardening School, held in their Gardens at Regent's Park, is excellent, supplying sound practical training under skilled instructors on most careful lines. Produce from the kitchen and flower gardens is not sent to market, as the work to a great extent resembles that of a large private garden, with the special advantage, in addition, of grounds devoted to "botanical" and economic plants. The students take part in every kind of work, excellent experience being afforded them in the propagating department and in flower gardening in and out of doors. The kitchen garden, which has been recently enlarged, also affords good experience in that department of which the war has shown us the immense importance, whether as small-holders or as teachers and superintendents.[1]

Some Openings for Women Gardeners.—Training completed, the question clamours for a definite answer: "What is my future as a gardener to be?" The following remarks are intended to give some indication of the openings available:—

PRIVATE SERVICE.—In this the duties are included of a small or a large garden, undertaken either single-handed or with help. Although not generally well paid, such posts provide very useful experience, and the life is usually a pleasant if a distinctly strenuous one for the worker. An under-gardener's place on the staff of a large "place" with a first-class head gardener (preferably, as a rule, a man) is, of course, one of the most advantageous opportunities for the

[1] It may be remarked here that at some gardening colleges the tendency is to make the course too light and pleasant. Young women have confessed to the editor that they had the happiest of times at their colleges but that when they came to take posts they found gardening a very different matter, for then the hard work started. College authorities might with great advantage remedy this matter and let their students "know the worst" long before they leave to start on their own.—EDITOR.

freshly trained but not very experienced woman gardener to take.

NURSERY AND MARKET GARDENS.—In these branches a woman gardener will almost invariably look forward to owning eventually "her own place." It may be pointed out, however, that in whatever line of work she may be employed, the all-round experience of a good nursery will be found invaluable.

JOBBING GARDENING.—The management of a nursery apart from a market garden involves less risk than the latter, owing to the fact that the grower is dealing with stuff which does not cease to be marketable at a given moment. Nursery work, moreover, can be combined with other departments of gardening, more especially with the working up of a consulting practice, or with the business of what is inelegantly known as "jobbing gardening." For both of these last, a proper knowledge of Design should first be acquired. But in the second type of work—that of the jobbing gardener—it must also be recognised that a thoroughly adequate staff is required, for the business side is exceedingly arduous in its demands. Speaking from a fairly wide personal experience a few years since, the present writer can say that where town work is concerned, it will prove most often a more satisfactory and certainly a more lucrative concern for a woman to devote all her energies to managing the actual gardens without keeping her own Nursery. She will, of course, *supply* all materials and plants, obtaining these directly from growers and contractors on wholesale trade terms. Such a business has been known to prove highly successful, and it certainly provides an interesting and varied existence for the right type of woman, although at the same time it is certainly one of considerable strain.

Advice on Market Gardening.—For the woman who wishes to run a market garden as distinct from a nursery garden and its kindred activities, great forethought is necessary. So variable indeed are the circumstances and conditions upon which success will depend, and so completely do they govern the situation, that an intending market gardener should take advice from one who knows the ropes before she risks her capital in this enterprise. But to the woman who makes the decision the following brief counsels are offered:—(1) Specialise, if only in one or two good things. (2) Aim at producing early vegetables and salad plants (*i.e.* "primeurs") on the French intensive system where possible. (3) Agitate for increasingly better conditions affecting the transport and marketing of stuff—at present a scandal to this country. (4) Supply direct to the consumer as much as you can, at all events until conditions improve.

Training of Students.—The owners of a nursery or a market garden may arrange to take pupils, provided that they can give the requisite time to do justice to their instruction, and that they are careful in the first place to admit only a serious (or sensible) type of woman student. During the war, one of the finest gardens in the country provided a splendid training ground for a number of women gardeners, following upon the introduction of one partially trained student who impressed the head-gardener favourably by her good and steady work; and the example had a wide effect for good from every point of view.

To those women gardeners who can join theory with practice, and add the gift of teaching to both, or who are able to furnish adequate premises and the necessary staff, the starting of a gardening school on sound practical lines will appeal as a work really worth doing—as indeed it is. Preparation will here be given for the usual examinations of the Royal Horticultural Society, and a sound foundation laid in theory and practice (more particularly the latter) for the National Diploma Examinations in Horticulture, and further still for the Degree in Horticulture under London University.

Horticultural Teaching. — Good posts are available for women gardeners as instructors in both public and private schools. The teaching thus given is, of course, entirely distinct from the training of professional gardeners as such. A Science degree or its equivalent is naturally desirable for this work, and in many cases essential; although it is actually true that more stress could often usefully be laid upon the practical side of the pupils' work and its essential relation to nature study and to other subjects of general education, rather than to emphasise a purely scientific interest in plant-life.

The action of the Ministry of Agriculture in organising, through its Horticultural Department, the services of lecturers, instructors, and superintendents throughout the country is one of the most hopeful signs towards developing a vast field hitherto largely untouched.

It may be interesting to mention that one of the highest authorities in the Horticultural Department of the Ministry, speaking unofficially to the writer early in the present year (1920), gave as his opinion that the appointment of women gardeners to posts such as those indicated above should not suffer the least prejudice on a question of sex.

There is no doubt that work of this type, both educationally and productively, opens up, under Government organisation, an immense field. Here again, it is practical experience, whether on the part of man or woman, which will count. The woman gardener who can demonstrate on a plot and not merely lecture on a platform, should command "equal pay for equal work" in the joint service she renders to education and food production on the small-holding and school garden ground.

In a former capacity as lecturer to teachers on school gardens under the London County Council, and as having a fairly wide experience through the holding of classes, organised publicly and privately, for allotment holders and teachers, the present writer can speak confidently of the extremely interesting character of, as well as need for, this work of horticultural education; and of its far-reaching results.

Conclusion.—To refer even distantly to the subject of education as a whole cannot fail in giving rise to ideas which it is beyond the scope of the present article to discuss. None the less, they are rooted in the need for a more constant recognition of Horticulture in its true position as an art, a science, and a craft; and to the consequent necessity for the best possible training of skilled gardeners who will also be fitted to organise, to inspect, and to teach.

We need such men and such women, experienced, thoughtful, and intelligent, whose balanced outlook and all-round knowledge will make them able to deal wisely with situations which present some of the most fascinating—if some of the most difficult—problems in the future of modern education and of modern life.—H. WOOD LILY.—See *TRILLIUM*.

WOOD PRESERVATIVES.

Rose poles, trellis poles, pergola poles, etc., will not last long unless the wood is treated in some way before the poles are let into the ground. Charring is recommended by some authorities, but this is not very satisfactory, and by far the best way is to paint the portions of the poles to be buried, with hot tar or pitch.

Creosote.—As regards the wood which is above the ground, this, too, should be treated especially in districts where the rainfall is heavy, or where there are frequent falls of snow. Apart from the advertised proprietary wood preservatives we know of none better than ordinary creosote. Two or three liberal paintings of this will increase the life of such poles by very many years, and not injure the plants in the least. Poles should, of course, be allowed to become thoroughly dry before being exposed to the elements.

WORM ERADICATORS.—See *WORMS.*

WORM GRASS (*Sedum album*).—See *SEDUM.*

WORMS.

Earthworms are the best friends of the gardener on account of the work they do in passing the soil through their bodies and mixing it with lime from their glands. They should thus be encouraged, and no attempt made to destroy them except when they are in pots or lawns.

Worm Eradicators.—In the cases just cited worms are a nuisance and must be eradicated. This is not hard to do without injury to plants or grass. For pot plants the best method is to give a good soaking of lime water.[1] The worms come to the surface of the pots without delay and may be taken out into the garden.

On lawns a different method of procedure is advisable. A 40-gallon hogshead is filled with water, and into this is stirred about 3 oz. of commercial corrosive sublimate. A thorough soaking of the liquid (which is very poisonous) is given to the lawn, and the worms swept up into heaps as they come to the surface. They should either be buried deeply or burnt, since they will kill poultry if fed to them.

Injurious Worms.—Besides earthworms there are, as gardeners know, many other worms, as, for instance, EELWORMS, SLUGWORMS, and WIREWORMS. These are exceedingly injurious and must be destroyed, or banished from the garden. Their general appearance and the best modes of dealing with them are given in our article on *INSECT PESTS.*

WORMWOOD.—See *ARTEMISIA* and *MEDICINAL HERBS*, and under ARTEMISIA in *SHRUBS.*

WOUNDS ON TREES.—See *TREE WOUNDS.*

WOUNDWORT.—See *STACHYS.*

WULFENIA (Nat. Ord. Scrophulariaceæ).—This genus consists of only two species, both of which are shade-loving plants and thrive in damp sandy and peaty soil. They are propagated by division of the roots in autumn or spring.

Wulfenia amherstiana.—This bears tufts of evergreen leathery foliage. Flowers rich purplish-blue on slender spikes. Flowering Period, July. Height, 9 ins.

W. carinthiaca.—Similar to above but bearing smaller purple-blue flowers in denser spikes in July. Height, 9 ins.

WYCH ELM (*Ulmus montana*).—See *TREES.*

[1] This is made by stirring up fresh quicklime with cold water until no more will dissolve. The excess of lime is then allowed to settle, and the clear liquid used.—EDITOR.

X

XANTHISMA (Nat. Ord. Compositæ).—The summer flowering *Xanthisma texanum* (Syn. *X. Drummondii*) is a very free flowering annual, with yellow flower-heads, growing about 2 ft. high. Sown out of doors in April, so as to form a group, and thinned to 1–1½ ft. apart, it is attractive in the flower border, or in spaces between shrubs.

XANTHIUM (Clot Bur. Nat. Ord. Compositæ).—This is a genus of weedy hardy annuals the value of which in the garden is practically *nil*.

XANTHOCERAS.—For the best species see *Shrubs*.

XERANTHEMUM.—See *Everlasting Flowers*.

XEROPHYLLUM (Turkey's Beard. Nat. Ord. Liliaceæ).—Only one species of this genus (*X. asphodeloides*) is at all generally grown. This is a pretty hardy herbaceous perennial useful for a sunny perennial or mixed border, and bears white flowers in May, averaging 1½ ft. in height. It may be grown, propagated, and planted in the same way and at the same time as other hardy perennials (see article on *Perennials: General Culture of*), but requires a peaty soil, and a damp situation.

XIPHION.—Now included in the genus *Iris*.

XIPHOPTERIS.—Now included in the genus Polypodium, for which see *Ferns and Fern Gardening*.

XYLEBORUS.—See Orchid Borer in *Insect Pests*.

XYRIDION.—Now included in the genus *Iris*.

Y

YAMA GUMI (*Elaeagnus glabra*).—See *Shrubs*.

YAMS.

We do not recommend our readers to attempt the cultivation of these in this country.

YARROW.—See *Achillea* and *Medicinal Herbs*.

YELLOW ADDER'S TONGUE (*Erythronium americanum*).—See *Dog's Tooth Violets*.

YELLOW ARCHANGEL (*Lamium Galeobdolon*).—See *Lamium*.

YELLOW BARK OAK (*Quercus velutina*).—See *Trees*.

YELLOW BIRCH (*Betula lutea*).—See *Trees*.

YELLOW CENTAURY (*Chlora perfoliata*).—See *Chlora*.

YELLOW CHESTNUT OAK (*Quercus Muehlenbergii*).—See *Trees*.

YELLOW CYPRESS (*Cupressus nootkatensis*).—See *Trees*.

YELLOW FUMITORY (*Corydalis lutea*). See *Corydalis*.

YELLOW GENTIAN (*Gentiana lutea*). See *Gentiana*.

YELLOW HAW (*Crataegus flava*).—See *Trees*.

YELLOW HUNDREDWEIGHT.—A decorative Gourd. See *Ornamental Gourds*.

YELLOW LUPINE (*Lupinus arboreus luteus*).—See *Lupine*.

YELLOW OAK (*Quercus Muehlenbergii*).—See *Trees*.

YELLOW PIMPERNEL (*Lysimachia nemorum*).—See *Lysimachia*.

YELLOW PINE (*Pinus mitis*).—See *TREES*.

YELLOW SPANISH BROOM (*Spartium junceum*).—See *SHRUBS*.

YELLOW STAR OF BETHLEHEM (*Gagea lutea*. Nat. Ord. Liliaceæ).—Gardeners must keep this distinct in their minds from the *STAR OF BETHLEHEM* proper (*Ornithogalum*), on which a separate article appears. The Gageas are dwarf-growing hardy bulbs bearing greenish-yellow flowers in April, and growing about 6 ins. high.

YELLOW TURK'S CAP (*Lilium pyrenaicum*).—See *LILIES*.

YELLOW UNDERWING MOTH.—See under SURFACE LARVÆ in *INSECT PESTS*.

YELLOW WATER LILY (*Nuphar*. Nat. Ord. Nymphaeaceæ).—This is a hardy water lily of some merit available in several forms. It succeeds best where there is about a foot of water above it. Its general culture is the same as that outlined in our article on *WATER LILIES*, which see. We recommend the following species :—

Nuphar advena.—Yellow flowers throughout the summer.

N. luteum (BRANDY BOTTLE).—Yellow flowers with strong spirituous odour throughout the summer.

N. minimum. — Yellow flowers from June to July.

N. polysepalum.—Yellow flowers from June to September.

YELLOW WOOD (*Cladrastis tinctoria*).—See *TREES*.

YESSO FIR (*Picea ajanensis*).—See *TREES*.

YEW (*Taxus baccata*).—See *TREES*.

YORK AND LANCASTER ROSE (*Rosa damascena variegata*).—See *ROSE SPECIES*.

YOUTHWORT (*Drosera rotundifolia*). See *SUNDEW*.

YUCCA (Nat. Ord. Liliaceæ).

This is a genus of most useful evergreens for the rock garden or wild garden as well as for the general borders and for sub-tropical bedding. Most of them are of easy culture and hardy enough to stand an average English winter, though in ultra-cold districts some protection may be advisable. Any good, light, rich, sandy soil suits them admirably, and they may be successfully propagated by seeds, cuttings, and suckers in the usual way. For bedding purposes they should be raised in the same manner as half-hardy annuals or propagated by cuttings the previous season.

What to Grow.—All those mentioned below bear white flowers from July onwards to September. Owing to the popularity of the genus many synonymous species are now offered, but to add these would be waste of space and would confuse readers considerably. The following may be regarded as distinct: *Yucca angustifolia*, and its variety *stricta* (2–3 ft.); *Y. filamentosa*, and its varieties *flaccida* and *variegata* (SILK GRASS, averaging 1½–3 ft. in height); *Y. glauca* (2–3 ft.); *Y. gloriosa*, the well-known ADAM'S NEEDLE, and its varieties *Ellacombei* and *variegata* (4–6 ft.); *Y. orchioides* and its variety *major* (1–3 ft.); *Y. recurvifolia* and its variety *variegata* (3 ft.); and *Y. rupicola* (1½–3 ft.).

In addition to the above species the following half a dozen of the best hybrids should be grown if space admits: *Albella*, *arnottiana*, *Orion*, *sanderiana*, *Sirius*, and *Vomereuse*. All have white flowers.

YULAN (*Magnolia conspicua*).—See *CLIMBING AND TRAILING PLANTS* and *TREES*.

Z

ZAUSCHNERIA (Californian Fuchsia. Nat. Ord. Onagraceæ).—There is only one species of this genus. It requires a warm, dry position in sandy loam fully exposed to the sun, and is propagated by division of the roots in spring.

Z. californica (Humming-Bird's Trumpet).—This has branching stems and hoary leaves. Flowers brilliant vermilion. Site sunny. Soil sandy, well-drained loam. Flowering Period, August to September. Height, 1 ft. The variety *mexicana* has less hoary leaves. It produces vivid scarlet flowers earlier than the species, namely, in July.

ZEA (Nat. Ord. Gramineæ).

This is an unimportant genus of annuals the hardiness of which is doubtful. The best known species, grown at times in the borders but chiefly in the kitchen garden, is *Zea Mays*, popularly known by various names, such as Guinea Wheat, Indian Corn, Indian Sugar Corn, Maize, Mealies, Sweet Corn, and Turkey Wheat. Its culture is described in our article on *Maize, or Indian Sugar Corn*.

ZELKOVA.—For the best species see *Trees*.

ZEPHYRANTHES (Atmasco Lily. Nat. Ord. Amaryllidaceæ).—This is a very ornamental early summer flowering pot plant, requiring ordinary greenhouse treatment and of easy culture. It is propagated by offsets, and should be potted in sandy loam, peat, and leaf-mould. Temperature required, 40–50° F.

Greenhouse Species :—*Zephyranthes Atamasco.*—Pure white. Flowers in May. Height, 1 ft.

Z. carinata.—Delicate rose. Flowers in May. Height, 1 ft.

Z. flava.—Pale golden-yellow. Flowers in May. Height, 1 ft.

ZEUZERA.—See Wood Leopard Moth in *Insect Pests*.

ZINC COMPOUNDS.

Very little is known of the horticultural value of the compounds of Zinc, though suggestions have been made to use such as Zinc Arsenide and Zinc Sulphate as fungicides. One point of importance to gardeners is that Zinc Sulphide is a white compound instead of a black one, as is Lead Sulphide. Thus when the greenhouses are syringed with Liver of Sulphur, no ugly blackening of paint results if Zinc is used instead of Lead when making the paint. We understand that Zinc Paint can be obtained without much difficulty, for after all it is only a matter of substituting Zinc Carbonate, or Zinc White as it is popularly called, in place of Lead Carbonate. Zinc Paint should be universally adopted by gardeners, since Liver of Sulphur cannot be done without, and then there will be no more complaints of spoiling the appearance of the houses by spraying to check diseases.—E. T. E.

ZINNIA (Nat. Ord. Compositæ).

This is an interesting genus consisting chiefly of half-hardy annuals some of which are particularly handsome when in bloom, and very valuable in gardens when the autumn is fine and warm. All the kinds mentioned below should be treated as half-hardy annuals and raised in gentle heat in spring. They require liberal treatment at all times to develop their beauty to the fullest extent, but a warm and sunny position is equally essential

from the time they are planted out in early June. They are very showy and give a wide range of harmonious colouring from almost white and fawn, through pink, yellow, and scarlet to crimson and purplish-red.

Zinnia elegans.—This is the most popular species of all both for border displays and as an exhibition flower. It is available in varied colour forms, flowers in the late summer and autumn, and averages 1½–2½ ft. in height.

Z. haageana.—This bears orange-yellow flowers from August to September, and grows 1½ ft. high.

Z. pauciflora.—This is a red, autumn-flowered species, about 2 ft. high.

Z. tenuiflora.—This seedsman's name probably indicates a variety of *Z. pauciflora.*—C. H. C.

ZIZIA.—Now included in the genus *Carum.*

ZONAL GERANIUMS.—The same as Zonal Pelargoniums.

ZONAL PELARGONIUMS. — See *Pelargoniums.*

ZONED PINK (*Dianthus callizonus*).—See *Dianthus.*

ZYGADENUS (Nat. Ord. Liliaceæ). This is a comparatively unknown but pretty genus of hardy herbaceous plants useful for the shady and moister parts of the herbaceous border. They will flower freely under these conditions if a little peat is added to the soil. They may be propagated by seeds sown in the usual way for hardy perennials, or by division of the root-stocks in November or March, at which times also they are most successfully planted. A large number of sorts have been described, but only five of them are grown. Four of these we briefly describe below :—

Zygadenus elegans (Syn. *Helonias glaberrima*).—A white sort blooming from May onwards, and growing 12 ins. high.

Z. glaberrimus.—A species producing creamy-white flowers about midsummer, and growing 12 ins. high.

Z. muscitoxicum (Syns. *Amianthimum muscitoxicum* and *Helonias laeta*).—This, popularly known as Fly Poison, bears white flowers in June, and averages 1½ ft. high.

Z. Nuttallii.—This also bears white flowers in June, and grows about 18 ins. high.

ZYGOCOLAX.—See *Orchids.*

ZYGONISTA.—See *Orchids.*

ZYGOPETALUM.—See *Orchids.*

CALENDARS
FOR WORK THROUGHOUT THE YEAR

CALENDARS
FOR WORK THROUGHOUT THE YEAR

THE pages which follow contain Calendars of work to be done in the various branches of the garden throughout the year. The writers, we may say, are all of them thoroughly practical men and well acquainted with their subjects, and it is hoped that this section of the Dictionary, which is included by special request, will be found extremely useful.

Very great effort has been made by each writer to make his Calendar as complete as possible, but since it is unlikely that any truly "complete" Calendar of Gardening ever has been or ever will be written, no apology is necessary for any omissions there may be.

The idea throughout has been to supply details of *When* to do the various things in the garden, and to leave the question of *How* to do them to the other contributors of the Dictionary. Calendars of this kind are extremely rare; on the other hand, the opposite kind are as abundant almost as are the new books on gardening which appear every year. Writers of such Calendars make a big mistake; they supply what is not wanted by the readers of any book or paper which has for the most part articles full of cultural details.

In the Calendars which follow explanatory cultural details have been carefully omitted, and the reader will not find many of them to worry him. We shall welcome suggestions for improving these Calendars.—THE EDITOR.

The Authors of the Calendars which are here combined are as follows :—

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS	THE EDITOR.
THE GREENHOUSE	CHARLES COMFORT.
HARDY FRUIT GARDEN	J. G. WESTON.
INDOOR FRUIT AND VEGETABLES	D. LEWIS.
VEGETABLE GARDEN	F. R. CASTLE.

NOTE.—In these Calendars it is assumed that the reader will use his discretion about carrying out the instructions here contained. It is extremely foolish, for instance, to attempt to plant shrubs or make structural alterations during frost. See article on *WEATHER AND GARDENING*.

JANUARY.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Trench all land intended for the making of new flower borders, whether for annuals, biennials, or perennials.

Lightly fork over the surface of existing perennial borders, working in some manure, if this was not done last November.

Lay turf for new lawns, after first levelling and rolling the ground.

Make new garden paths and renovate old ones. Frequent rolling of gravel or any loose surface paths is desirable.

Make any needful alterations in the flower garden, such as the formation of new borders, etc.

Plant shrubs of all kinds. Firm planting is essential for success.

Weed the surface of lawns if it has become bad. Brush the surface regu-

larly to distribute worm casts, and roll at least once a week.

Plant hardy perennials of all kinds. Make them very firm.

Go over perennial borders planted in November and December, treading the soil firmly round the plants again after a thaw.

Re-set any edging stones which may be inclined to sink into the borders.

Make out the flower seed order and get it dispatched as early as possible. A penny or twopence spent on each variety of flower will give you ample seeds unless the garden is one of great size.

Protect herbaceous plants, such as Aquilegias and others which are not quite hardy, by putting mounds of cocoanut fibre or ashes over them.

Protect alpines, especially Androsaces and certain Sedums and Saxifrages possessed of hairy foliage by placing sheet glass over them.

Re-write or renew all weathered garden labels.

Make out the order for new herbaceous plants early in the month if you have not had time to do it before.

Make plans for new bedding or planting schemes in the garden. The long evenings in January are just the time for this work.

Trim grass verges of paths to give the pleasure grounds a neat and smart appearance.

Layer hardy shrubs provided the weather is exceedingly open.

Loosen the surface soil amongst bulbs to give them a chance of rapid growth.

Lay in a stock of turf, peat, leaf-mould and manure for further work, and especially for top-dressing the rock garden.

Refrain from mulching perennial borders and rose-beds until later on, or much good food will be wasted.

Prepare trenches for Sweet Peas without delay.

Prepare sites for Dahlias, Chrysanthemums, and other plants if showing is contemplated.

Dust Carnations and other choice plants in the special borders of the garden with lime or soot, remove dead leaves from them, also weeds and other rubbish.

Protect Auricula and Polyanthus plants in very severe weather.

Protect the less hardy shrubs in hard weather with mats, etc.

Plant hardy bulbs left over from the winter—the sooner the better.

Rake dead leaves and rubbish off the surface of shrubberies as early as possible.

THE GREENHOUSE.

Introduce batches of bulbs fortnightly from the "plunge" or cold frame.

Introduce a few pots of Doronicum and Solomon's Seal to furnish cut flowers.

Propagate Chrysanthemums for bush plants, selecting for cuttings shoots which have been well exposed to the light.

Give a top-dressing of rich soil to any Chrysanthemum plants which are backward in furnishing cuttings.

Cut over and remove Chrysanthemum plants when they have finished flowering and sufficient cuttings have been secured.

Shift Chrysanthemums intended for the production of big blooms into 3½-inch pots.

Give Herbaceous Calceolarias their final shift into 7-inch pots towards the end of the month.

Sow tuberous-rooted Begonias in shallow pans and place in heat.

Propagate the following edging plants by cuttings in heat: *Fuchsia Cloth of Gold*, *Fuchsia procumbens*, *Origanum Dictamnus*, and Tradescantias in variety.

Shift Hydrangeas intended for the production of single trusses into 5-inch pots, using a rich compost.

Re-pot ferns if pot-bound or if drainage be deranged.

Top-dress ferns requiring this attention.

Stand bulbs in a cold frame to ripen off, as they go out of flower, and gradually reduce the supply of water to them.

Prune and train climbing plants on wall or rafter.

Shift Pelargoniums into their flowering pots, ramming the soil rather firmly.

Give close attention to ventilation in cold weather with fitful periods of sunshine.

Damp down the fire during the day, unless the conditions be cold and sunless.

Drain and provide with suitable soil the site where any permanent climber or other specimen is to be planted.

Pot varieties of *Lilium auratum* and *L. speciosum*, and stand in a cold frame or in the coolest part of the house.

Order all necessary seeds, relying chiefly on well-tried varieties.

Make hanging baskets with wire netting, by means of a cutting-pliers.

Paint the inside of watering-cans as a preventive of corrosion by rust.

Remove promptly all spent blooms, dead foliage, and other decaying matter.

Prune specimen Fuchsias, and return to their former position.

Give Freesias liquid manure bi-weekly.

HARDY FRUIT GARDEN.

Proceed with planting operations of all kinds of fruit trees, especially on light well-drained soils.

Prepare cuttings of bush fruits, and insert during mild weather.

Carry out draining operations during the winter months. This is particularly necessary in heavy retentive soils for the choicer fruits, such as Nectarines, Peaches, dessert Plums, and Cherries.

Prepare stakes, labels, and soils for planting, in bad weather.

Renovate neglected orchard trees during the winter.

Grub out useless worn-out trees. Head back inferior varieties for future grafting, if stocks are healthy.

Prepare fruit tree washes for use in calm weather.

Spray fruit trees after pruning with a concentrated alkali wash, to remove mosses and lichens.

Continue root pruning in mild weather.

Examine fruit trees for American blight, and if found, dress thoroughly with an approved specific.

Protect Fig trees from severe frosts in cold districts, but do not leave them permanently covered.

Prune outdoor Vines this month, and afterwards paint with a sulphur mixture to prevent mildew.

Top-dress the vine-roots with a compost consisting of good loam, lime rubble, and crushed bones.

Plant out red, white, and black Currants on well-prepared ground.

Prune Raspberries and train on strained wires, or tie on strong stakes if preferred. Avoid crowding the canes in either case.

Shorten the stronger canes of Raspberries to about 5 ft. Clear the beds of all weeds and rubbish, afterwards digging between the rows.

Mulch raspberry beds with a good dressing of farmyard manure, late in the month.

Stake and securely tie all newly planted fruit trees.

Examine labels on fruit trees, and replace with new ones if necessary.

Prune yearling Black Currant bushes to within a bud or two of the ground, thus ensuring strong fruiting wood for another season.

Continue all pruning operations in suitable weather.

Burn all prunings, rubbish, and perennial weeds in a slow fire. Mix the ashes with some new soil and manure, and return to the ground as a top-dressing.

Use lime-rubble freely when planting any stone fruits.

Examine bush fruit cuttings regularly, and re-firm all loosened by frost.

Wheel out manure to the fruit quarters during frosty weather.

Treat fruit trees and bushes bearing regular crops generously with manure.

Trench ground for new raspberry beds, digging in plenty of farmyard manure, and some crushed bones and lime as the work proceeds.

Clean all rubbish from strawberry beds, and lightly fork between the rows.

Examine all old stakes to fruit trees, replacing any decayed at the base.

INDOOR FRUIT AND VEGETABLES.

Water permanent Fig tree borders. Close the house and maintain a night temperature of 50° F. Open ventilators a little on sunny days: closing early after syringing and damping down.

Sow seeds of Melons singly in 3-inch pots for the first crop.

Start early Peach trees in the usual way. Syringe the trees.

Bring the first batch of Strawberry plants into the greenhouse.

Maintain temperature of 55° F. for Vines started in December, and cease syringing when well on the move. Water the border.

Cleanse late Vines and top-dress the borders.

Make up hotbeds of leaves and manure for forcing early vegetables.

Plant Asparagus roots on hotbeds, or in heated frames, for an early supply of grass.

Sow Dwarf Beans for early work in house or pit where a temperature of 60° F. can be maintained. Pot up December sown plants.

Sow Cucumbers for early work.

Sow Lettuce seed in a warm house, pricking out in due course and growing on rapidly.

Sow Mustard and Cress in boxes under the stage of a warm house, transferring to near the glass as soon as germinated.

Lift a few roots of Mint and Tarragon to force in mild heat for early cutting.

Start forcing Potatoes in early fruit houses.

Sow seeds of early Dwarf Peas in 9-inch pots, placing in a warm greenhouse.

Plant a few Seakale crowns weekly to maintain supply.

Sow Tomato seeds in a temperature of 65° F. Put autumn sown plants into 5-inch pots, placing them near the glass in a warm house.

Keep hotbed and Lettuce frames matted nightly until danger of frost has passed.

VEGETABLE GARDEN.

Sow Mazagan, or if preferred, one of the white-seeded Broad Beans on a warm border.

Select seed tubers of early varieties of Potatoes, setting these eyes upward in shallow boxes in a light frost-proof shed.

Get all ground operations completed as early in the month as possible.

Use soil fumigants for pest-ridden soils.

Sow round seeded sorts of Peas on dry soils.

Sow seed of exhibition Onions now in a warm greenhouse if extra fine bulbs are wanted.

Sow seed of Cabbage or Cos Lettuce in pans or boxes, to give hearts from a warm outside border, early in May.

Sow Radishes in a warm border, always selecting a rich bed, and in the event of extra sharp frosts give the bed a covering of straw or hay.

Lift strong clumps of Rhubarb for forcing, to succeed the clumps put into heat earlier in the winter.

Prepare hotbeds for forcing Asparagus, or Carrots of the shorthorn type, using a light soil for the carrots.

Sow seeds of early Cauliflowers in a heated greenhouse.

Sow Cucumbers for an early crop in single pots.

Sow Tomato seed early in the month.

Look frequently over Lettuce or Endive in cold frames, removing every decaying leaf, and giving air when conditions are favourable.

Protect rows of Celery growing in exposed situations. Dry straw or bracken is best for this purpose.

FEBRUARY.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Push forward all kinds of structural alterations, amendments, and additions to the garden.

Build new rock gardens, wall gardens, etc.

Make Japanese Gardens, Water Gardens, etc., as advised in the special articles on these subjects.

Plant hardy perennials of the following and many other sorts: Achillea, Anchusa, Anemone, Aquilegia, Aster (Hardy), Campanula, Centranthus, *Chrysanthemum maximum* and *C. uliginosum*, Delphinium, Digitalis, Doronicum, Erigeron, Galega, Geum, Helenium, Helianthus, Inula, Lupinus, Lychnis, Paeony, Papaver, Pentstemon, Phlox (Hardy), Polemonium, Pyrethrum, Ranunculus, Rudbeckia, Solidago, Trollius, Verbascum, and Veronica.

Plant all perennials very firmly, in borders which have been prepared well in advance.

Plant Roses of the following and many other sorts:—

Climbers.—Alister Gray, Bouquet d'Or, Gloire de Dijon, Climbing Caroline Testout, Gruss an Teplitz, Climbing Kaiserin Victoria, Climbing Lady Ashtown, Maréchal Niel, Climbing Mrs Grant, Madame Berard, W. A. Richardson, Reve d'Or, American Pillar, Philadelphia Rambler, Crimson Rambler, Blush Rambler, Alberic Barbier, Dorothy Perkins, Hiawatha, Excelsa, Minnehaha, etc.

Dwarfs, etc.—Captain Hayward, Avoca, Bessie Brown, Earl of Dufferin, Lady Roberts, Hugh Dickson, Mrs Sharman Crawford, Countess of Gosford, Dean Hole, Lady Ashtown, Mildred Grant, Killarney, La Tosca, Madame Ravary, Lady Pirrie, Mrs Alfred Tate, William Sheen, Richmond, Pharisaer, Viscountess Folkestone, Mrs Myles Kennedy, Prince Arthur, Ulrich Brunner, Ben Cant, Harry Kirk, etc.

Continue laying lawns if this work was not completed last month.

Prune hardy shrubs.

Thin growths on climbing Roses.

Erect new arches, arbours, pergolas, etc.

Fork over shrubberies, working in a little manure.

Overhaul the rock garden. See to its plants and its labels, renewing any of either which are done for.

Go over the winter bedding and make any plants which have been loosened by recent frosts firm again.

Re-firm any newly planted stock of any kind, whether it be shrubs or perennials, after frost.

Roll lawns and paths regularly at least once each week.

Prick over the surface of existing borders should this get caked after rain and sun.

Lift and divide any perennial plants which have grown too thickly.

Remove weak dying wood from climbing Roses in mild weather.

Inspect rock plants and see that the protection afforded is sufficient. February rains and fogs often do more damage than February frosts.

Plant any remaining spring flowering bulbs without delay, or the bloom they give will be very late. All the commoner ones in addition to Fritillaries, Scillas, Anemones, Ranunculuses, Ixias, Aconites, etc., may be planted this month.

Protect early flowering Irises.

Plant hardy shrubs.

Complete all trenching of flower garden land by the end of the month.

Plant bulbs after forcing, in the wild garden.

Dress vacant flower borders with naphthalene or other fumigating material to destroy soil pests.

Paint labels in readiness for further planting next month. Write them while they are still wet.

Complete as early as possible any work in the flower garden which has had to be held over from January.

THE GREENHOUSE.

Stake Daffodils and Hyacinths before there is danger of the flower stems getting damaged.

Introduce more bulbs from the "plunge" or cold frame, and see that they are well supplied with water.

Sow seeds in moderate heat of *Asparagus Sprengeri*, *Cordyline indivisa*, *Eucalyptus citriodora*, and *Grevillea robusta*.

Break up old plants of *Francoa ramosa* and pot up the pieces furnished with aerial roots, into 4-inch pots.

Pot off autumn-struck cuttings of *Crassula* (*Kalosanthes*) *coccinea* into 3-inch pots, using a sandy loam compost with some charcoal in it.

Propagate Perpetual Flowering Carnations, inserting the cuttings in sandy soil in a heated structure.

Cut over plants of *Salvia splendens*, to induce them to break and furnish a supply of cuttings.

Give weekly applications of liquid manure to Mignonette in pots.

Shift into 6-inch pots autumn-sown Sweet Peas to be flowered indoors.

Introduce *Azalea mollis*, *Dielytra spectabilis*, Lilacs, and other shrubs intended for flowering indoors.

Re-pot, towards the end of the month, established plants of *Agapanthus umbellatus*; *Crassula coccinea*; *Hydrangea hortensis* and its varieties; *Sparmannia africana*; and *Trachelium coeruleum*.

Remove all decayed parts, trim and top-dress Selaginellas, or other plants growing alongside the pathways.

Remove a little of the surface soil in borders where climbing plants are growing, and give a top-dressing of fresh soil suitable for the different subjects.

Pot off rooted cuttings of Chrysanthemums intended for bush plants, placing two plants in each pot.

Stake and tie Mignonette in pots, using quite short slender stakes.

See that there is a sufficient stock of labels and stakes in hand.

Continue to look over the plants for water in the morning, taking care not to spill water about the house.

Remove any moss or weeds from the surface of the pots, and wash any dirty pots.

Keep a sharp look-out for aphis, and on its first appearance vaporise or fumigate, but if only a few isolated plants are attacked, apply a little tobacco powder with a "puff."

Increase the ventilation as the month advances, but avoid cold draughts.

Apply liquid manure to Cinerarias and Primulas twice a week.

Remove bulbs as they go out of bloom, and rearrange the occupants of the house from time to time.

HARDY FRUIT GARDEN.

Trench ground for new strawberry beds, working in plenty of well-rotted manure.

Plant wall fruit trees in favourable weather.

Postpone planting of fruit trees during wet weather, or when the ground is sticky.

Mulch newly planted fruit trees with light material only; heavy yard manure keeps the soil cold.

Prune and train Apricots on walls.

Thin the spurs on old Pear and Plum trees, cutting back to a healthy bud at the base.

Fork over fruit-tree borders lightly, after pruning and training is completed.

Prune Cobnuts and Filberts this month; keep the centres of dwarf nut-bushes quite open, and restrict the number of main stems.

Clear off all suckers springing from the base of Cobnuts and Filberts, and give a dressing of lime, forking into the surface.

Give a good dressing of manure to nut-trees that have borne heavy crops.

Watch Apricots, and early Peaches on warm walls, and prepare blinds for protecting the blooms against frost.

Avoid heavy permanent coverings for the hardy fruits: a double thickness of fish netting is usually a simple and effective protection.

Avoid putting on protective material before the blooms commence to open. If thick blinds are used they must be removed in the day-time.

Root-prune unfruitful Fig trees and restrict their root-run.

Postpone transplanting or root-pruning fruit trees on heavy soils during wet weather.

Complete all spraying operations before the buds commence to burst.

Fill up blanks in the raspberry beds.

Look over fruit nets in bad weather, repairing all damaged ones for future use.

Top-dress peach and nectarine borders with a mixture of new loam, lime rubble, bonemeal, and wood ashes, treading or ramming it very firm.

Prune and train Morello Cherries, discarding any old fruiting wood, and giving the young shoots plenty of room.

Scrub the bark of any old fruit trees infested with scale insects with a reliable insecticide, to ensure a thoroughly clean start for the season.

Train the shoots of Loganberries and American Blackberries very thinly if on a trellis, and give the roots a heavy dressing of manure.

Net Gooseberries and Red Currants against bullfinches and tits, or use black thread liberally through the branches.

Cut down to within a few inches of the ground late-planted Raspberry canes, to ensure strong canes for future fruiting.

Plant autumn fruiting Raspberries in an open sunny position.

INDOOR FRUIT AND VEGETABLES.

Disbud early Fig trees in pots to avoid overcrowding, stopping the shoots retained at the fourth joint.

Prepare and plant early beds for Melons.

Ventilate freely all hardy fruit houses, fumigating when growth commences. Afford a little fire-heat when the trees are in bloom and maintain a buoyant atmosphere. Pollinate the blooms on sunny days.

Give a little top air daily to Peach trees in bloom, and increase the temperature 5°. Distribute the pollen by tapping the trellis work about noon daily.

Gradually increase the temperature for early Strawberry plants and syringe daily, starting further plants for succession.

Rub off the weak shoots on early Vines, retaining only one growth to each spur, tying down with care. Pinch out the tips of the shoots at the second leaf beyond the bunch.

Plant more Asparagus roots for succession, admitting a little air daily as growth proceeds.

Sow Dwarf Beans at intervals of three weeks, syringing daily plants in active growth.

Plant a few Chicory roots in a warm house and keep quite dark.

Sow Early Shorthorn Carrots on a hotbed, and thin out to 3 ins. apart.

Plant out Cucumber plants on hillocks 3–4 ft. apart.

Apply salt and water, or weak stable manure water to Mushroom beds showing signs of exhaustion.

Plant Potatoes on hotbeds, and keep those growing in pots near the glass, admitting air whenever possible.

Sow Radish seed very thinly on hotbeds.

Pot Tomato seedlings in 3-inch pots,

giving a little air on sunny days. Repot autumn sown plants to 10-inch pots.

Sow Early Forcing Turnips on hotbeds, thinning out the seedlings to 6 ins. apart.

Sow Vegetable Marrow seeds in heat of 65° F., for early cropping in frames.

VEGETABLE GARDEN.

Prick out Tomatoes from seed sown last month, using a nice sandy compost. When the roots have taken well hold of the new soil, give ventilation but avoid draughts.

Lift the crop of Jerusalem Artichokes if not already done and store the tubers in dry quarters, or in a heap under the shelter of a wall, covering with a few inches of soil.

Sow a little more Cauliflower seed in a heated greenhouse this month to give heads outside in June.

Force strong clumps of Rhubarb growing in the garden by covering with a good depth of fermenting material.

Fill any gaps which frost or insects may have caused in the cabbage bed. Give well-established runs a good dressing of old soot or a light sprinkle of nitrate of soda.

Sow Cabbage seed in heat for a succession.

Sow further supplies of Carrots, either in a cold frame or in a gentle hotbed. Thin those sown last month and give air on all suitable occasions.

Sow maincrop Parsnips, protecting the young plants from slugs.

Plant a few rows of early Potatoes at the end of the month where the soil is exceptionally light, and warm borders can be spared to the crop.

Prepare the bed intended for Onions, using manure freely. Leave the surface of the bed in a rough state.

Thin out autumn-sown Onions where these are crowded, transplanting the surplus to other quarters where manure has been freely used.

Earth up rows of early-sown Peas or Beans as soon as the plants push through the soil.

Make further sowings of Peas and Beans, selecting a warm position.

Make the first sowing of Spinach in a warm border when land is dry enough. Either the prickly or round-seeded variety is suitable.

Lightly fork over the surface of established asparagus beds, afterwards applying a good coating of rich manure.

Prepare ground for new asparagus beds.

Get all ground operations finished by the end of the month, in preparation for next month's busy time.

MARCH.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Complete the digging over of vacant borders as early as possible.

Rake down and break the surface soil of borders in readiness for sowing seeds.

Sow seeds out of doors of any of the following among many other hardy annuals: Acroclinium, Asperula, Calendula, Candytuft (*Iberis*), Clarkia, *Convolvulus minor*, Eschscholzia, Eutoca, Gaura, Godetia, Jacobaea (*Senecio*), Leptosiphon, Lupinus, Malope, Mignonette, Nemophila, Nigella, Phacelia, Saponaria, Shirley Poppies, Silene, Sunflowers, Sweet Sultan, and Virginian Stock.

Sow Sweet Peas very thinly in the prepared trenches. Plant out what were sown indoors last month towards the end of this month.

Complete the planting of most hardy perennial plants by the middle of the month, or late flowers of poor quality will result.

Thin out autumn-sown annuals and hoe the ground between them. Weed them thoroughly.

Push forward the work without delay, if rose-beds and perennial borders have not yet been lightly turned over and manure worked in. Do the work with great care so as not to injure the roots.

Complete any garden alterations not yet accomplished without delay, for delays are dangerous.

Complete the planting of hardy shrubs and Roses if the weather last month did not admit of this being done.

Finish the winter pruning of hardy shrubs and climbers, and commence the pruning of Rose trees towards the end of the month.

Plant out Carnations which have been wintered in frames, surrounding them by rings of lime or soot.

Slightly loosen the soil around choice bulbs which are now appearing in the borders.

Continue planting bulbs which have been forced, out into the wild garden.

Commence mowing the lawn towards the end of the month.

Commence tying up perennial plants (Doronicums, etc.) towards the end of the month. These plants will be flowering early in April.

Prepare sites for early flowering border Chrysanthemums and Dahlias, if this has not already been done.

Top-dress the rock garden with a mixture of light, sandy loam, leaf-soil, and old manure, making the new soil very firm.

Go over the whole of the contents of the rock garden at the end of the month, removing protection. Remove at the same time any dead leaves or shoots. Renew labels.

Tie up newly planted shrubs and mulch them with peat or manure.

Complete the tidying up of existing shrubberies without a moment's delay.

Top-dress Azaleas and Rhododendrons with a mixture of equal parts old hotbed manure, oak leaf-mould, and turfy loam, to encourage them to do their best in flowering.

Sow Anemones in small drills for future use.

Plant hardy Gladiolus.

Plant hardy Lilies.

Sow Stocks out of doors in a warm bed.

Dress rose-beds with Tonk's formula, rotted dung, or sewage.

Protect all young perennials, especially Delphiniums and Pyrethrums, from slugs by rings of soot or lime.

Complete as early as possible all work held over from last month.

THE GREENHOUSE.

Shift *Clarkia elegans* and *Schizanthus Wisetonensis* into their flowering pots, those of 7-inch diameter being generally suitable.

Make sowings of *Kochia trichophylla* and *Zea japonica Four-Coloured Perfection*, in gentle heat.

Propagate *Libonia floribunda*, *L. Penrhosiensis*, *Sparmannia africana*, and *Trachelium coeruleum* by cuttings.

Give young plants of Malmaison Carnations their final shift into 6-inch pots.

Re-pot Malmaison Carnations retained for a second year.

Pot off rooted cuttings of Perpetual Flowering Carnations into thumb pots.

Pot off autumn-sown Cyclamens into 3-inch pots, taking great care not to injure the brittle, fleshy roots.

Give Clarkias and Schizanthuses a final pinching towards the end of the month.

Propagate by cuttings Zonal Geraniums for winter flowering.

Shake out and re-pot Zonal Geraniums to be retained for a second year.

Divide Cannas with a sharp knife and start into growth in shallow boxes, among leaf-mould, in moderate heat.

Sow the following Primulas in gentle heat: *P. malacoides*, *P. obconica*, and *P. sinensis*.

Divide and re-pot *Primula Kewensis*.

Start Crinums into growth by standing them in full light and applying water in increasing measure as growth proceeds.

Shift on Crinums if necessary, bearing in mind that they succeed best when somewhat confined at the root.

Give *Vallota purpurea* rather more liberal supplies of water now, and when growth becomes active give occasional doses of weak liquid manure.

Dust Roses affected with mildew with flour of sulphur, or spray with potassium sulphide.

Start tuberous-rooted Begonias in gentle heat, by arranging them in a tray on which some flaky leaf-mould has been placed.

Shift Sweet Peas into their flowering pots, and supply them with dwarf twiggy stakes to support them till placed in their permanent positions.

Give occasional applications of liquid manure to Deutzias, Richardias, and Roses.

Keep a sharp look-out for frost, and if it occurs increase the fire-heat as necessary.

HARDY FRUIT GARDEN.

Mulch fruit trees which bear regular crops heavily, especially on light shallow soils.

Cut autumn fruiting Raspberry canes down to ground-level, as the fruits are produced on the current year's growth.

Mulch all newly planted fruit trees before drying March winds are experienced.

Plant Strawberries from pots wintered in cold frames, or from nursery beds.

Protect the various wall fruit trees as they commence to blossom.

Complete all arrears of pruning

immediately, as the sap will now be on the move.

Prune any Gooseberries which were left till late to avert damage by birds.

Prune Gooseberries severely now if extra large dessert fruits are wanted.

Fork the soil up lightly under fruit bushes, following this up with a mulching of half-decayed manure.

Sow seeds of Alpine Strawberries in pans or boxes, and place same in a temperature of about 50–60° F., to germinate. Keep them moist.

Dispense with winter coverings for Figs. Train and prune the trees.

Complete all arrears of fruit planting, and do not let the roots get dry by long exposure to the air.

Spray Pear trees with a suitable insecticide for the pear fly, just before the blossom opens.

Paint Apple trees infested with American blight with pure paraffin.

Examine Black Currants for big bud. If attack is slight, hand pick and burn. Burn badly infested bushes.

Tread the soil round bush fruit cuttings if loosened by frost, to make them quite firm in the ground.

Remove all sucker growths from the roots of Nectarine, Peach, and Plum trees.

Top-dress any exhausted Peach trees with rich soil and manure, using bone-meal, charcoal, and lime rubble, with a good proportion of new loam.

Spray Nectarine and Peach trees before growth commences, to prevent leaf-curl.

Continue planting Loganberries and other brambles, but mulch immediately as a protection against drying winds.

Cut down to ground-level all extra late-planted Raspberries and Loganberries.

Prune maiden Nectarine and Peach trees to from four to six buds, weak shoots to three buds.

Cut back maiden Plum trees to six buds, in order to make a good foundation for the future tree.

Shorten the growths on maiden Apricots to four buds.

Complete the pruning of Fig trees, and train all growths very thinly.

INDOOR FRUIT AND VEGETABLES.

Spray Fig trees with soap and liver of sulphur solution to prevent red spider. Attend to the thinning and pinching of the shoots.

Pinch out the points of all lateral growth of Melons at the second leaf, and syringe the plants two or three times a day. Sow seeds for general crop.

See February Calendar for remarks on hardy fruit trees in pots. These apply for present month.

Disbud early Peach trees and tie the shoots neatly on the trellis. Thin out Peach fruits on the trees, leaving two per square foot. Fumigate the early Peach house to ward off attacks of fly and aphis, maintaining a buoyant atmosphere in the late Peach house when the trees are in bloom.

Thin Strawberry fruits to seven on a plant and increase the temperature as the fruits are swelling. Give the plants weak liquid manure two or three times a week, admitting plenty of air to maintain a buoyant atmosphere as the fruit ripens and cease syringing.

Bring more Strawberry plants into the house for a succession.

Start the late vinery, and guard against too high a temperature until growth is active. Increase the temperature by 5°, and admit a little air daily for Vines in bloom. Water the borders.

Thin early Grapes while the berries are small.

Thin bunches of Grapes to one on each shoot.

Give liquid manure to Dwarf Beans twice a week after the pods are set.

Syringe Cucumbers freely and maintain a warm, damp atmosphere.

Plant Lettuce in frames and keep fairly close until growth is active.

Make up a late Mushroom bed.

Hoe up Potatoes in frames, giving air on all favourable occasions.

Grow on Peas in pots in a very light house and afford them plenty of air.

Sow Radishes in a cold frame for succession.

Plant a few Seakale crowns weekly in an unheated dark shed for late supplies.

Plant out maincrop Tomatoes, and pinch out side growths as they appear. Sow seeds for May planting in deep frames and cold greenhouses.

Put Vegetable Marrow plants into 5-inch pots, and keep them growing in a warm house near the glass.

VEGETABLE GARDEN.

Remove all weeds from asparagus beds and give a light dressing of salt. Make up new beds in readiness for planting early next month.

Complete the planting of Jerusalem Artichokes.

Plant out Broad Beans, which have been raised in heat early in the year, into the open. Sow again for succession.

Divide Chives, replanting them in well-manured soil.

Sow any of the shorthorn varieties of Carrots in a sheltered border early in the month.

Sow maincrop Leeks out of doors. Harden off Leeks sown in January in heat.

Keep seedlings of large growing varieties of Onions (sown early in the year) near the glass, and give air freely.

Plant Potato Onions, as early in the month as possible; also Onion Sets, or large bulbs for seed.

Plant Shallots if not already done.

Sow any of the most hardy varieties of Peas early, delaying the marrowfats until after the middle of the month.

Make a small very thin sowing of Turnips in a warm border, giving these a well-manured soil.

Plant earliest varieties of Potatoes, burying the sets at least 6 ins.

Sow French Breakfast, or one of the turnip-rooted varieties of Radishes.

Sow Spinach Beet and Kohl Rabi out of doors.

Sow Couve Tronchuda in a frame early in the month.

Sow Marrowfat Peas after 15th March, whenever the state of the soil allows this to be done without being sticky.

Plant out Peas sown in boxes or pots early in the year, protecting these with dwarf bushy sticks.

Sow Broad Beans any time this month.

Force Seakale outside.

Make new beds of Seakale this month.

Sow the maincrop of spring Onions as early in the month as the state of the soil allows.

Use the hoe freely among all growing crops.

Plant Jerusalem Artichokes early in the month.

Continue to plant out Cabbages, making the soil about the roots very firm.

Prick out Celery sown in boxes last month.

Sow Broccoli outside for early autumn use.

Sow Cauliflower and any of the small hearting varieties of Cabbage.

Make small sowings of Leeks, Lettuce, and Savoy Cabbage.

APRIL.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Sow seeds of any and all the annuals named last month in good finely raked soil, either in clumps, irregular patches, or lines.

Sow any of the following hardy annuals in little pockets in the rock garden: Alyssum (Sweet), *Asperula azurea*, *Kaulfussia amelloides*, *Leptosiphon densiflorus*. *Limnanthes Douglasii*, Meconopsis, *Nemophila insignis*, *Omphalodes linifolia*, *Silene pendula compacta*.

Commence hoeing the perennial border. Care is needed early in the month not to injure young shoots of plants.

Hand-weed lawns to remove plantains, dandelions, etc. Apply lawn sand.

Clip Ivy climbing on the house, garden walls, banks, or tree stumps in the wild garden, choosing a calm day for the work.

Rake over shrubberies and herbaceous borders after well hoeing them to impart a neat appearance, and to remove surplus stones.

Plant out Sweet Peas sown indoors last month.

Plant out Calceolarias and Pentstemons with an edging of *Alyssum maritimum*.

Plant out Violas of all kinds which have been wintered in frames, as early this month as possible.

Plant out Pansies in rich soil.

Give plenty of water to perennials planted last month if the weather is dry, to enable them to establish themselves in their new quarters.

Prick off hardy annual flowers sown last month in reserve beds.

Thin out all hardy annuals as soon as they are large enough to handle conveniently.

Complete the work of planting alpines in the rock and moraine garden as early in the month as possible, and do not let them lack water.

Complete the pruning of Roses this month.

Mulch Roses with manure this month. The mulching is of special importance in the case of newly planted trees.

Gather flowers regularly from the

herbaceous border. If the plants are not allowed to produce seed and ripen it, their flowering periods will be considerably extended.

Continue the routine work of staking and tying up, also the protecting of choice plants from garden enemies, which was commenced last month.

Plant out Border Chrysanthemums in firm, rich soil.

Trim up both plant and grass edgings to give the garden a neat, smart appearance.

Remove dead flowers from rock plants as fast as they go out of bloom.

Prune rampant growing rock plants such as Arabis, Aubrietia, Cerastium, Vinca, etc., if they are inclined to overrun their quarters.

Sow more Sweet Peas about the end of the month to give ultra-late blooms.

Sow more hardy annuals during the final week of April for succession.

Plant out Spiraeas from the greenhouse, also Ericas, etc. etc. Those required again for indoor work may simply be plunged. Thus they need much less care and water.

Plant out perennials and biennials raised in heat.

Complete the renovation of paths, drives, etc., to give the garden a neat appearance.

Feed Polyanthuses and Auriculas with dilute liquid manure.

Plant out Hollyhocks.

Fill up gaps in mixed borders caused by late frosts, with young annuals, biennials, and perennials from reserve beds.

Commence propagating various perennial plants by removing small basal growths now being freely produced. Insert these in sandy soil in a shady site, preferably covering them with a frame or hand-light.

Cut bulbous flowers now open in the pleasure and wild garden freely, and, above all, prevent them from ripening seed, or they will be much weakened.

Loosen the land in which Ranunculuses are planted, and later in the month assist them in their growth with liquid manure.

Sow Herbs for the herbal section of the flower garden.

Clip dead flowers off Pansies and Violas regularly once or twice a week. If this is continued throughout the summer they will continue blooming until October.

Protect choice Daffodils, Tulips, etc., which are going to be exhibited, from rain and wind, otherwise they will be spoilt.

Sow Carnation seed for next season.

Sow seeds of sweet-scented flowers in a special section of the pleasure garden. They may be associated with herbs.

Make or complete plans for summer bedding in readiness for next month. See articles on *Colour Gardening*, *Bedding Out*, etc. etc.

Follow up and complete as early as possible any work in the flower garden described under March if, owing to circumstances, it was not finished in that month.

THE GREENHOUSE.

Shift late struck Perpetual Flowering Carnations of the previous year into 6- or 7-inch pots according to their vigour.

Shift on Camellias requiring more room at the root before active growth commences.

Give weekly applications of liquid manure to Camellias making young growth, excepting those which have been re-potted recently.

Propagate Abutilons, Cytisuses, *Diosma ericoides*, and Epacrises by cuttings.

Re-pot or top-dress Epacrises as necessary before they start into active growth.

Pot up Cannas into 5-inch pots as they start into active growth.

Pot off into small pots cuttings of various plants as they become rooted.

Stake and tie Clarkias and Schizanthuses, using slender stakes.

Shift bush Chrysanthemums into 5-inch pots, and transfer to a cold frame.

Pinch bush Chrysanthemums when they attain a height of 4 ins.

Re-pot *Clivia miniatum* and its varieties. If it is desired to increase the stock, break up the clumps and pot up the bulbs singly.

Pot up tuberous-rooted Begonias as growth becomes active.

Re-pot Ivy-leaved Geraniums, after which stake and tie the plants.

Pot off *Grevillea robusta* and other seedlings sown during the previous two months.

Shift on Bamboos if necessary; if not remove a little of the surface soil and top-dress with a rich compost.

Re-pot *Bambusa Fortunei* var.,

Eulalia japonica [var., *Eulalia Zebrina*, and *Isolepis gracilis*.

Re-pot established plants of Abutilons, *Aloysia citriodora* (Lemon-scented Verbena), and Eupatoriums.

Discontinue the application of fire-heat, except when frost occurs.

Damp the pathways in the mornings on sunny days.

Increase the ventilation as the month proceeds, but still guard against cold draughts.

Keep aphis in check by means of vaporising or fumigating.

Shift Perpetual Flowering Carnations now in thumb pots, into those 3 ins. in diameter.

Apply moderate shading as necessary from the middle of the month onwards.

Take seed of any extra good Cinerarias.

Secure seed of the various Primulas, if available.

Pinch growing Fuchsias, but allow at least ten days between the operations of potting and pinching.

HARDY FRUIT GARDEN.

Complete the pruning of all fruit trees on north walls.

Mulch late-planted fruit trees of all kinds, to keep the soil moist.

Examine Gooseberries for caterpillar, and hand-pick or spray according to circumstances.

Clean up strawberry beds, forking in a liberal dressing of artificial manure and soot, and finish off with a mulch of well-rotted manure.

Disbud Apricots on south walls on warm days, but postpone the operation if cold weather prevails.

Examine fruit borders under glass copings and walls regularly for moisture. If found necessary heavy soakings should be given, driblets are useless.

Train Blackberries on a fence or wall in sunny position.

Hoe strawberry beds frequently to keep them clear of seedling weeds.

Spray Black Currants with a mixture of soft soap and quassia if big bud develops.

Disbud Peaches and Nectarines, commencing at the top of the tree, and continuing at intervals of five or six days.

Graft Apples, Cherries, Pears, and Plums, as soon as the sap is running.

Fork lightly over stiff soils, round newly planted fruit trees in dry weather, to prevent soil from cracking. Replace light mulching afterwards.

Syringe transplanted trees showing signs of distress every warm afternoon.

Spray Apricot trees occasionally with quassia extract, to keep them clear of insects.

Syringe Plum trees on walls regularly after the fruit is set.

Watch for red spider on Peaches, and take preventive measures early.

Soak the plum border well when the crop on wall trees is set.

Give liquid manure water or artificial fertilisers to all fruit trees carrying heavy crops, and water it well in.

Disbud outdoor Vines when the shoots are about an inch long.

Finish all grafting without delay.

Plant hardy Vines from pots, spreading out the roots carefully, before covering with soil. Make the soil quite firm, and apply a light mulch at once.

INDOOR FRUIT AND VEGETABLES.

Syringe Fig trees twice daily and increase the temperature as the fruits are swelling, seeing that the borders do not suffer for lack of water.

Pinch out the points of Melon shoots at one leaf beyond the fruit.

Pollinate female Melon blooms when three or more are out at once and maintain a drier atmosphere while the fruits are setting.

Fumigate orchard house fruit trees that have set their bloom, and syringe the trees twice daily.

Maintain a buoyant atmosphere for Apples and Pears coming into bloom.

Give a fair amount of air to early Peach trees as the fruits are stoning, and spray with liver of sulphur to check red spider.

Dress peach borders with an approved fertiliser and water well in. Disbud and tie the growths and thin the fruits as often as necessary.

Bring in the last batch of Strawberry plants, and bring them on in an ordinary greenhouse without much heat.

Syringe Strawberry plants freely if growing in warm houses, affording copious supplies of water.

Plant young Vines early in the month, shortening the canes to within 18 ins. of the soil.

Dress vine borders after grapes are thinned with an approved vine manure, watering it well in.

Afford Muscat Vines a higher temperature when in bloom.

Ventilate fruit houses at this season with caution. Give all air possible, avoiding cold draughts, and close early.

Sow Dwarf Beans for succession. Syringe the growing plants often to keep red spider in check.

Sow Cucumbers for planting out in frames next month. Feed plants cropping heavily with frequent doses of liquid manure.

Plant Marrows on mild hotbeds, one plant to each light.

Plant Seakale thongs a foot apart in rows 18 ins. asunder.

Draw the lights off Carrot, Turnip, Lettuce, and Potato frames on warm sunny days.

Thoroughly water vegetables in frames if approaching dryness.

VEGETABLE GARDEN.

Sow Peas early in the month for use about the middle of July.

Put suitable support to early sown Peas: if sticks are unobtainable, use wire netting or strong twine.

Plant new asparagus beds early in the month. Sow Asparagus seeds for transplanting next spring.

Sow a few short rows of Globe Beetroot for early autumn use, on an unmanured plot.

Plant out Onions intended for large bulbs.

Sow winter greens of all sorts early in the month.

Plant out Cauliflowers sown in heat in February into the open garden.

Sow Cardoons and Celeriac in a frame if not already done.

Sow early varieties of Carrots in a warm border.

Sow Parsley early in the month, in rich soil.

Plant well-sprouted early varieties of Potatoes on a warm border, and watch carefully for the first appearance of those planted last month.

Give asparagus beds a good sprinkling of old soot, salt, or nitrate of soda, 2 oz. to the square yard.

Sow the maincrop of Celery early in the month, on a gentle hotbed.

Make up hotbeds for Frame Cucumbers, or early Vegetable Marrows.

Sow Seeds of Perpetual Spinach.

Sow Lettuces and Endive in the open ground.

Plant Shallots in rows 10 ins. apart, allowing 8 ins. between the bulbs.

Sow Onions in beds prepared last month.

Sow Tomato seeds in a heated house, or pot early this month for outdoor cropping later.

MAY.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Mow all the lawns and trim the grass verges in the pleasure grounds at regular intervals of one week.

Roll paths and drives every Saturday. Give them a good brushing at least once in fourteen days.

Plant out Dahlias in rich positions in full sun. Set stakes to them immediately.

Lift bulbs from the flower borders and plant them in the wild garden.

Continue to plant bulbs from the greenhouse in the wild garden.

Sow seeds of British Wild Garden Flowers in bare patches in the wild garden.

Sow more hardy annuals for successional flowering, both in the rock garden and general parterre.

Sow seeds of Auriculas and Polyanthuses for blooming next spring.

Lift and divide Polyanthuses after they have finished flowering, for blooming next spring.

Keep the hoe going freely through the numerous flower borders.

Pull up winter bedding plants about the middle of the month.

Dig the borders thoroughly for summer bedding plants, working in plenty of well-decayed manure at the same time.

Plant out all kinds of half-hardy general and carpet bedding plants after well hardening them off.

Water all borders for bedding plants very thoroughly if the weather is dry, in order to give the flowers a good start.

Peg down any trailing plants, *i.e.* Ivy-leaved Pelargoniums, as soon as they are planted out.

Keep all newly planted bedding stuff thoroughly well watered.

Plant out in slightly shady spots such plants as Arums, Spiraeas, etc. etc., which have been forced.

Sow seeds of the following among many other half-hardy annuals out of doors: Ageratum, Amarantus,

Arctotis, Balsam, Browallia, Celosia, Dimorphotheca, Helichrysum, Mimulus, Nemesia, Portulaca, Rhodanthe, Salvia, Tagetes, and Zinnia.

Sow seeds of biennials such as *Campanula pyramidalis*, Canterbury Bells, Hollyhocks, Honesty, Myosotis, Œnothera, Scabious, Sweet William, and Wallflowers.

Thoroughly thin out hardy annuals as they grow, otherwise they will smother and stifle themselves.

Continue the staking of all manner of border plants, remembering that "a tie so soon prevents their doom."

Continue to propagate perennial plants from offshoots, inserting these in slight shade and sandy soil.

Continue the lifting of Polyanthuses and Auriculas; dividing the large plants to obtain suitable stock for next season.

Mulch choice subjects in the perennial border with short, or old hotbed manure.

Sow more herbs if the sowing last month failed to be satisfactory.

Continue gathering flowers from borders regularly and frequently, also remove all dead flowers at once.

Cut down early flowered herbaceous plants as soon as they have ceased blooming, mulch with rich manure and apply liquid manure with a view to getting a second crop of flowers.

Prick off annuals from reserve beds into the mixed borders as they become ready, and as soon as gaps appear in those borders.

Remove seed heads from Rhododendrons and other choice flowering shrubs as soon as the flowers fade.

Clip dead flower heads from rock plants, and continue to cut them back after they have finished blooming.

Attend to routine work in the pleasure grounds, and see that it never gets a day in front of you.

Train Rose shoots over arbours and arches, tying them in early to prevent them being damaged.

Commence propagating Wallflowers from cuttings. This should only be done in the case of choice double varieties.

Thin blooms of extra choice sorts of Asters and other bedding plants, if already showing.

Dry off any bulbs not required for the wild garden by placing them on the surface of a sunny border in a thin layer.

Continue to weed lawns.

Propagate Violets.

Commence making plans for winter bedding and autumn alterations of all kinds.

Scrutinise the borders and make a note of any clashing colours to be changed in the autumn.

Weed borders regularly.

Prepare further reserve beds for seedlings used in winter bedding.

Complete any work for April which could not be done during that month.

THE GREENHOUSE.

Transfer young plants of Perpetual Flowering Carnations to a cold frame, and provide them with plenty of fresh air.

Stake and tie Carnations, Geraniums, and Pelargoniums, making the stakes as inconspicuous as possible.

Pot off rooted cuttings of Cytisus, which were taken last month.

Stand Chrysanthemums out of doors on ashes, in a sheltered position, not overhung by trees.

Furnish Chrysanthemums with temporary dwarf stakes.

Fill hanging baskets with such subjects as *Asparagus Sprengeri*, Begonias, *Fuchsia Cloth of Gold*, Ivy-leaved Geraniums, trailing Lobelias, and Tradescantias.

Sow Cinerarias in a pan or box in a cold frame, and do not overlook the claims of the graceful Star and Cactus types.

Stake and tie Herbaceous Calceolarias, using bamboo tips or other slender stakes.

Fumigate or vaporise Calceolarias to rid them of any lurking aphis, before the plants come into bloom.

Place Primulas to be retained, in a cold frame for the summer, and remove the remainder to the backyard.

Shift on all young growing stock as necessary, a safe general rule being to use pots two sizes larger than those the plants have just occupied.

Give Agapanthuses, Carnations, Geraniums and Pelargoniums occasional applications of liquid manure.

Pinch Carnations, Geraniums, and any young plants requiring this attention to promote the formation of a bushy habit.

Re-pot Primulas retained for future use.

Prick off Primula seedlings into pans or boxes, and place them in a frame for the summer months.

Top-dress Liliums as the fleshy roots show on the surface. Increase the water supply as growth proceeds.

Continue to keep a sharp look-out for aphis or thrip, and if present apply the antidote previously recommended.

Leave on some top ventilation overnight towards the end of the month if the weather is seasonable.

Damp the pathways in the mornings if there is sunshine.

Make a start with the final potting of Chrysanthemums, towards the end of the month, taking the big bloom class in hand first.

Re-stake Chrysanthemums temporarily as potting proceeds.

Shake out Cyclamens that have finished flowering and plant them out in a bed of rich soil in a cool pit or frame.

Spray Cyclamens twice daily and shade from bright sunshine.

HARDY FRUIT GARDEN.

Examine fruit borders to see if water is required.

Spray Peaches and other fruit with a mixture of sulphur, soft soap, and water, against mildew.

Examine newly grafted trees and remove all shoots below the graft. Cut suckers away at once.

Hoe all fruit borders and quarters regularly, to keep a loose tilth on the surface.

Thin the shoots on raspberry beds, leaving only a limited number of the best according to space.

Look out for black aphis on dessert Cherries, and syringe with an insecticide as soon as seen. Syringe Cherries regularly with soft water, to keep foliage clean and healthy.

Remove all gross shoots from wall-trained fruit trees, as, if left, these upset the balance of growth.

Plant out forced Strawberries, dipping them first in a sulphur mixture to eradicate red spider.

Water newly planted Strawberries to ensure a quick start. Hoe regularly to keep down seedling weeds.

Remove all protective material from fruit trees and carefully dry all blinds and netting. Label, and store it in a dry place.

Examine Apple trees for aphis, and spray early if the slightest trace is seen.

Water transplanted fruit bushes freely in dry weather.

Disbud Peaches and Nectarines, leaving sufficient shoots for extension.

Tie shoots on grafted stocks firmly to small sticks, to ensure support in stormy weather.

Spray grafts daily in very dry weather.

Partially thin the fruits on Apricot trees, leaving the remainder till after the stoning is finished.

Syringe all wall trees regularly on fine afternoons.

Dust Gooseberry bushes with hellebore powder for caterpillar, or spray with quassia extract.

Hoe between Strawberry plants on warm borders, and place clean straw down to keep the fruits clean.

Place nets over Strawberries in good time to protect the fruit from birds.

Pinch growths on cordon Pears back to the fourth leaf.

Thin the side shoots on bush fruit trees.

INDOOR FRUIT AND VEGETABLES.

Maintain a warm dry atmosphere for Fig trees in pots ripening their fruits, and cease syringing.

Water permanent Fig tree borders with liquid manure.

Support Melon fruits to prevent injury from damp.

Sow Melon seeds for late crops, putting out plants sown earlier in frames and matting the lights nightly.

Supply pot fruit trees with copious supplies of water, and occasional doses of weak liquid manure. Spray with soap and liver of sulphur.

Keep on a current of air night and day for Peach trees ripening their fruit, and fix a net under the trees.

Syringe and damp down late Peach houses twice a day and admit air freely when warm and sunny.

Thin Grapes, and allow short stalked kinds ample room. Stop sub-laterals at frequent intervals.

Give more air to Vines ripening their fruit and leave on nightly a chink of air top and bottom.

Make a sowing of Dwarf Beans in a cold span-roof frame, to precede those sown out of doors.

Sow seeds of Chicory in a sheltered position.

Throw the lights off Carrot, Turnip, and Potato frames towards the end of the month.

Put out Cucumber plants in spare hotbed frames, one plant under each light in a barrow-load of rich loamy soil.

Give weak liquid manure frequently to Peas swelling their pods, and afford all the light and air possible.

Fill any available deep frames with Tomato plants.

Top-dress Tomatoes that have set heavy crops of fruit with rich loamy compost, and apply occasionally a good chemical manure.

Pollinate female flowers of Vegetable Marrows, and pinch out the points of the shoots regularly.

VEGETABLE GARDEN.

Fill empty garden frames with strong Cucumber plants.

Plant out well-hardened Tomato plants against a south wall or in other sheltered positions.

Sow ridge Cucumbers where the crop is to mature. After 15th May Cucumbers raised in heat may be planted out.

Endeavour to get a good breadth of early Cauliflowers put into permanent quarters early in the month, in order that these may become well established by midsummer.

Give timely attention to all crops in the open garden requiring thinning out, but avoid unduly disturbing the beds when the soil is very dry.

Sow seed of Dwarf Beans any time this month.

Sow Runner Beans, if possible setting the seed near supply of water.

Make several sowings of Lettuce during this month; one at least where the crop is to mature.

Sow Corn Salad for summer and autumn eating.

Give Shallots a good application of old soot, or, if it can be had, a real good soaking of liquid manure.

Earth up Potatoes as soon as the tops are well through the soil, but avoid burying these too deeply.

Water Radishes and Saladings very freely.

Plant out Globe Artichokes and Cardoons in rich ground.

Use the hoe freely between Turnip rows and give liberal applications of an approved fertiliser.

Sow seeds of Bush Marrows in the open air early this month, or plant out seedlings growing in single pots into rich soil.

Pinch out the tips of all Broad Beans as soon as black fly is seen.

Sow Curled Endive for early use, selecting a shady border.

Plant out the main batch of Celery early this month.

Prick out seedlings of the various winter greens, sown in March, into temporary quarters. Keep the soil well watered.

Sow more Peas for succession, earthing the runs now showing through the soil.

Water rows of Peas showing flower freely in dry weather.

Feed asparagus beds in full "cut" freely with liquid manure.

Plant out Leeks for early winter use before 15th May in a very rich soil.

Sow Beetroot on well-dug soil, avoiding a site recently manured.

Sow a few rows of Salsafy early in the month, choosing a deeply dug soil.

Clear away all old Cabbage stumps as soon as the heart is cut, unless later shoots from these are desired, in which case keep the bed free from weeds.

Put Couve Tronchuda, Celery Cabbage, etc., into their permanent positions as soon as large enough.

JUNE.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Continue the work of planting out summer bedding subjects with all possible speed on the same lines as mentioned last month.

Water newly planted bedding stuff every evening or in the early morning.

Water hardy annuals very frequently.

Water half-hardy annuals repeatedly to encourage strong growth if the weather be hot.

Water plants in the reserve flower garden just as much as those in the principal borders, since, if gaps occur in the latter, the plants in the reserve beds will be wanted.

Water the rock garden and the wall garden regularly and systematically if the weather is hot, otherwise many choice plants will perish.

Water the garden paths if the weather is exceptionally baking. This will produce a steam or mist most acceptable to the plants in the borders.

Water the lawn before any of the grass on it turns brown. These patches once formed are hard to get green again.

Water the shrubbery only in the driest of dry weather. In the case of newly planted shrubs, however, much more frequent watering is necessary.

Water the rose garden fully and freely, or the first blush of bloom will be badly affected.

Water your perennial or herbaceous

border before the plants start drooping and withering for want of moisture.

Water all florists' flowers and decorative plants intended for exhibition fully and frequently, since water for these is more important than for any others.

Water plunged pot plants generously, as their roots, unless they have come through the bottom, have only the moisture in the limited space of the pot to utilise.

Prune hardy shrubs about the middle or the end of the month, using sécateurs for the large leaved sorts to prevent damaging the leaves.

Fork over the surface of shrubberies after pruning is complete.

Sow Wallflowers, Myosotis, *Alyssum saxatile*, etc. etc., for winter bedding about the middle of the month if not already done.

Propagate Arabis, Aubrietia, Alyssum, etc. etc., by cuttings inserted in a shady reserve border.

Sow seeds of biennials for display in the mixed border, if not done last month.

Sow seeds of any of the perennials mentioned in February.

Sow a few more annuals for autumn blooming to fill up gaps in borders. This is the final sowing.

Cut hardy flowers regularly and frequently.

Cut Roses and Sweet Peas more freely than any other flowers.

Cut Lupines, Delphiniums, Anchusas, Doronicums, and similar plants down to the ground. Give a heavy mulch of manure and plenty of water with a view to obtaining September bloom.

Hoe herbaceous and general borders frequently.

Mulch all kinds of hardy plants with month-old cow dung if weather is hot.

Weed clumps of annuals by hand, and give the early sown ones their final thinning.

Prick out and re-plant annuals from the reserve beds into the general borders as soon as gaps are formed, and shade them lightly for a few days.

Prick out biennials and perennials 4 ins. apart each way, from seed sown last month.

Weed the rock garden. Continue to cut dead flowers off plants which have ceased blooming.

Continue to cut back rampant rock plants which are encroaching overmuch.

Protect Catmint (*Nēpeta Mussini*) from cats, or it will soon be spoilt at this season.

Continue the weeding and mowing of the lawns.

Roll and sweep all walks and drives at regular intervals.

Dress weedy walks with salt or weed killer in hot, dry weather.

Burn all undesirable garden rubbish, seed heads, seeding weeds, etc., making only the soft harmless material into vegetable manure.

Remove seed heads from Rhododendrons and other choice shrubs.

Propagate perennials from "root cuttings" towards the end of the month.

Complete the lifting of bulbs from the borders, either planting them in the wild garden or laying them out to dry.

Shake soil off bulbs laid out last month. Clean them and store in boxes till next winter.

Continue all routine work, staking of herbaceous plants, thinning of their growths, removal of suckers, and of weeds nestling round the base of the plants.

Complete the removal of Polyanthuses from the spring beds as early as possible.

Make potpourri.

Make rose water.

Make scent from Stocks, and other sweet-smelling flowers. The early blooms usually carry more of it than those produced later.

Take the top bud out of Clarkias, Calendulas, Godetias, Helichrysums, and many other annuals in order to produce bloom on side-shoots.

Thin out the growths of Sweet Peas. If too many shoots are left the plants produce fewer flowers.

Clip Box edgings.

Cut back encroaching edging plants such as *Armeria maritima* (Thrift), etc., as soon as they have finished flowering.

Propagate Pinks by pipings inserted in a sandy soil.

Continue to train in climbing Roses and other similar plants, taking care not to injure their bloom.

Propagate Sweet Williams by cuttings or layers.

Propagate Iberis, Pansies, and Sweet Rockets by cuttings for early work in winter bedding.

Keep a sharp look-out for all kinds of garden pests, especially for aphis, and apply remedies at once.

Start saving seed of choice plants if this is to be done. In order that it shall be true to name, artificial fertil-

isation is necessary, also protection from bees.

Mow the grass in the wild garden. Any bulbs planted in it will not now be injured, as they are resting.

Continue making plans for next autumn's alterations. Go carefully over the entire garden this month, and if any part does not please you, plan out schemes which will.

Complete any work held over from May as early in June as possible.

THE GREENHOUSE.

Complete the potting of Chrysanthemums, leaving ample room for top-dressing.

Stake and tie all Chrysanthemums as soon as the work of potting is completed.

Stand big bloom Chrysanthemums on a hard bottom and lash the stakes to a strained wire.

Plunge bush Chrysanthemums in ashes or soil, in the latter event stand the pots on a small inverted pot.

Remove Nile Lilies to the open, placing them in a sunny situation, to facilitate the ripening process.

Break up Nile Lilies, and plant singly in shallow trenches, where this system is preferred.

Top-dress Roses and stand outside on a hard bottom and in full sunshine.

Keep a sharp look-out for aphis or mildew on pot Roses. Spray with soft soap and quassia chips for the former, and with potassium sulphide for the latter.

Prick off Cinerarias into boxes, rather widely apart, and place in cold frames.

Move frames so that they shall face north, for the reception of Calceolarias, Cinerarias, and Primulas.

Apply a light shading to frames facing south, and containing greenhouse plants other than those just mentioned.

Remove Indian Azaleas and Greenhouse Rhododendrons to a vinery or other warm house until they have made their annual growth and set their flower-buds.

Stand hard-wooded plants in the open air, on a hard bottom, selecting spots shaded from the midday sun, but not overhung by trees.

Plant *Azalea mollis* in the reserve garden with a view to using it for greenhouse decoration after a two-years' rest.

Stake and tie Liliums, taking care not to tie tightly or close to the point of the shoot.

Sow *Humea elegans* and *Rehmannia angulata Pink Perfection* at the beginning of the month.

Sow Herbaceous Calceolarias towards the end of the month. Cover the seed very lightly, place a sheet of glass over the seed-pan, and shade.

Cut away or tie down any extra vigorous shoots on hard-wooded plants to regulate the flow of sap, and to preserve the symmetry of the plant.

Introduce such stove plants as Achimeneses and Gloxinias into the cool greenhouse.

Stake and tie Rehmannias, using quite slender stakes.

Spray or syringe daily with a fine rose, Azaleas, Carnations, and Cyclamens.

Syringe Chrysanthemums in the afternoons of hot days.

Attend to watering in the early morning or late afternoon, the latter period being preferable.

Sprinkle the pathways morning and afternoon to produce a humid atmosphere.

Leave on both side and top ventilation continuously, during the summer months.

Remove all decayed flowers and foliage promptly, and keep weeds in check.

HARDY FRUIT GARDEN.

Mulch raspberry beds with rotten manure or a dressing of artificial manure, to assist fruit to swell.

Disbud outdoor Vines, leaving one shoot to a spur; train very thinly.

Spray Cherries, after the fruit is set, with quassia extract to keep down aphis.

Remove any Peach shoots damaged by aphis, and syringe regularly to keep trees clean.

Train growths on all Nectarine and Peach trees very thinly; many trees are ruined by crowding the growths.

Examine Apricots for maggot, and, if found, clear by hand-picking.

Water Apricot trees during a dry spell, as drought will cause the fruit to fall.

Thin dessert Cherries to ensure fine quality fruits.

Thin green Gooseberries as soon as large enough for bottling or for culinary use.

Tie or nail the shoots of Peaches regularly to keep the trees in good form. Take out all gross shoots, as these rarely make fruitful wood.

Feed and water Strawberries to assist the berries to swell quickly.

Protect late Strawberry blooms from June frosts in damp districts.

Put nets over strawberry beds to protect from birds.

Pinch the shoots on trained Apples and Pears, leaving the leaders for the present.

Thin the fruits on Strawberry plants if an especially fine crop is required.

Thin the fruits moderately on both Nectarines and Peaches, but reserve the final thinning till after the stoning period.

Keep peach borders well watered. Dryness at the root will cause fruits to fall, or arrest development.

Watch transplanted fruit trees closely, syringing and watering regularly in hot weather.

Thin the fruits on early varieties of Apples. Varieties such as *Lord Grosvenor* or *Early Victoria*, which usually set far too many fruits, need severe treatment.

Stop the side-shoots on bush Apples, but do not stop the leader.

Thin Gooseberries grown for dessert severely in order to get good quality fruit. Stop all side growth on Gooseberries, water copiously, and use plenty of manure, mulching the borders after watering.

Keep a watch on Gooseberry bushes for caterpillars and red spider.

Cut off and burn the tips of infested shoots if gooseberry mildew appears.

Put down straw on the latest strawberry beds after hoeing.

Water late Strawberries heavily during dry spells to assist the fruits, applying artificial or liquid manure previously.

Prepare for layering early Strawberry runners for forcing in pots next spring, or for planting on south borders.

Prepare ground for new strawberry beds a few weeks in advance.

Disbud outdoor Vines, and when developed stop the shoots at the second leaf beyond the bunches.

Loosen ties on newly grafted trees and tie the shoots to small sticks.

Remove all suckers from the base of fruit trees.

Spray red and white Currants to keep them free from aphis.

Dip shoots of Cherries infested with black fly in a good insecticide.

Regulate the shoots on wall Cherry trees, and pinch lateral growth at fourth leaf.

Thin dessert Cherries on walls, and if necessary spray before netting.

Thin the fruits on Apricot trees finally, and pinch back all shoots not required for extension.

Water Apricots with liquid manure, or give a dressing of artificial fertiliser to help the fruits to swell.

Regulate growth on Fig trees according to their condition. Train the shoots very thinly. Use manure only on trees carrying full crops.

Pinch off side-shoots on cordon Pears, but leave the leader growing.

Thin Pears moderately, giving final thinning when they are swelling freely.

INDOOR FRUIT AND VEGETABLES.

Give air freely to Fig trees ripening their fruits, and see that the borders do not lack water.

Admit more air to Melons as the fruit ripens, and maintain a warm, buoyant atmosphere. Plant for succession in the border as soon as all fruits are cut and the plants cleared out.

Pinch the shoots of pot fruit trees to encourage the formation of fruit buds.

Soak early peach borders with liquid manure after the fruits are all gathered. Spray the trees well with an effective insecticide to preserve healthy foliage, and syringe twice daily until the leaves fall. Keep ventilators fully open night and day to ensure thorough ripening of the wood.

Make preparations for layering Strawberry runners prior to forcing.

Thin late Grapes, allowing ample space for large berried kinds.

Give abundance of air night and day to ripe Grapes and maintain a dry atmosphere. Attend constantly to pinching and regulating the shoots.

Give Dwarf Beans in frames plenty of air, and afford copious supplies of water.

Syringe and damp down Cucumber houses several times a day. Pinch and tie in the growths almost daily.

Open the ventilators of the Tomato house wide on hot days, and allow at all times a little air.

Sow Tomato seeds for winter cropping.

VEGETABLE GARDEN.

Thin out Carrots sown last month to 3 ins. or 4 ins. apart. After thinning give the bed a dusting of old soot.

Sow seed of Chicory early this month for forcing in November.

Discontinue cutting Asparagus after 7th June.

Give asparagus beds a good coating of fat manure, or encourage the roots to build up strong crowns by repeated applications of liquid manure.

Sow more French Beans. Should the soil be dry, well water the drills before sowing.

Plant out Maize or Sweet Corn, Cardoons, and Celeriac, raised in heat last month, selecting a spot where water can be most easily supplied.

Plant out Ridge Cucumbers and Vegetable Marrows, sowing more for late supplies.

Lift the earliest planted Potatoes towards the middle of the month. Should the season be a dry one give the rows of these abundant watering.

Dust Onions intended for large bulbs very freely with soot, to keep mildew in check.

Reduce the shoots on each crown to one—the strongest—on beds of Seakale formed last spring.

Give Winter Onions a light dressing of nitrate of soda early this month, washing this well down to the roots with weak liquid manure.

Protect the heads of Cauliflowers on plants raised in heat from strong sunshine, or they will lose their whiteness.

Plant out further Cauliflowers for late summer and early autumn use. Do not stint water.

Make successional sowings of Lettuces, Radishes, Corn Salad, Endive, etc., to maintain a supply.

Give frequent dustings of well-slaked lime in early mornings to young Turnips just forming the true leaf.

Reduce Spinach seedlings while still small to about 9–12 ins. apart.

Transplant Beetroot in showery weather, and if possible shade for a few days from bright sun.

Make a good sowing of Carrots to provide a succession of sweet roots from August onward.

Water frame Vegetable Marrows carefully, or many of the earliest fruits will turn yellow.

Prolong the Marrow supply by cutting all fruit when of fair size.

Remove the tops of Pea shoots on rows now in flower if early pods are desired.

Mulch Runner Beans and other crops with strawy manure, grass clippings, etc., to conserve moisture.

Pull up early Peas. Fork land over and plant with Lettuces and Saladings.

JULY.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Feed bedding plants with weak liquid manure.

Feed, hoe, and water hardy annuals as they need it.

Water and feed half-hardy annuals to encourage their bloom.

Continue watering the rock garden, reserve garden, and lawn if the weather be very dry.

Feed choice shrubs with weak liquid manure, especially if they were newly planted.

Feed Roses with liquid cow dung and soot.

Feed, hoe, and water the perennial or herbaceous border.

Feed florists' flowers, and give drinks of liquid dung to all decorative plants intended for exhibition purposes.

Feed Sweet Peas only seldom, since too soppy or rich a root-run will produce shoots instead of flowers.

Feed plunged pot plants now flowering freely, since they above all need extra food.

Continue the pruning of hardy shrubs if work was not completed last month.

Clip Privet, Hawthorn, and Holly hedges.

Burn all hard garden rubbish, as, for instance, hedge clippings and shrub prunings.

Fork over base of hedge and shrubbery borders after raking off clippings.

Sow more Wallflowers and other winter bedding plants if last month's supply is not satisfactory.

Prick out seedling Polyanthuses, Auriculas, etc., from seed sown last month.

Prick off seedling perennial plants, also biennials as they become ready.

Lift Canterbury Bells and Sweet Williams from the borders they have been in, planting backward bedding plants in their places.

Cut all flowers regularly and frequently.

Remove all dead blooms from border plants.

Hoe herbaceous and indeed all

flower borders frequently throughout the month.

Continue propagating Arabis, Alyssum, etc., for winter work.

Propagate rock plants by cuttings.

Propagate Geraniums from cuttings by inserting in a sunny position out of doors.

Propagate Pinks from pipings.

Continue mulching and weeding hardy plants as they need it.

Continue removing dead flower heads and cutting back lanky growths of all rock plants.

Cut Pansies back, lifting them out of the borders into the reserve garden.

Continue propagating perennial plants from root cuttings.

Dry off bulbs ready for re-planting.

Make more potpourri and rose-water, remembering that time flies.

Prune climbing Roses and other climbers if they have finished blooming.

Remove seed heads from flowers as fast as formed.

Start budding Roses.

Thin Dahlia growths and tie in all strong shoots.

Pinch tops out of border Chrysanthemums if they are running up too high.

Apply salt or other weed killer to weedy walks.

Disbud annuals to induce better flowers.

Shorten Fuchsia shoots.

Peg down rampant growing plants of trailing description to keep them in their places.

Syringe Petunias, Verbenas, Nemesias, and other choice bedding plants with weak insecticide to keep them clean and cool in warm weather.

Trap wireworms troubling choice plants.

Attend to Evening Primroses as to tying before they fall over.

Propagate Roses by cuttings.

Lift Ranunculuses, Polyanthuses, etc., if not already done.

Weed and generously hoe shrubberies.

Attend to all routine work in order that the garden may look as neat and happy as possible.

Complete all work held over from last month promptly.

THE GREENHOUSE.

Attend to the tying of Chrysanthemums as growth proceeds.

Stand Pelargoniums out of doors in full sunshine as soon as they have finished flowering.

Remove all decayed flowers from Pelargoniums, and gradually reduce the supply of water to them.

Shift young Cyclamens into their flowering pots towards the end of the month.

Continue to spray the entire stock of Cyclamen, morning and afternoon, taking care not to expose the plants to the direct rays of the sun.

Cut back the flower stems of second year Perpetual Flowering Carnations, after which re-stake and tie the plants.

Pot on young stock of Perpetual Flowering Carnations.

Shift the stock of *Salvia splendens* into its flowering pots, and keep the frame rather close for a week after the operation.

Find out by a slight pressure between the forefinger and thumb whether Greenhouse Rhododendrons and Indian Azaleas have set their flowering buds, and if they have, stand them outside in a sheltered position.

Continue to watch for mildew on pot Roses, and if it appears, apply the antidote previously recommended.

Stand winter-flowering Geraniums out of doors on a hard bottom in full sunshine to ensure the shoots being well ripened.

Place *Vallota purpurea* outside in a sunny position, to assist in ripening the bulbs.

Water *Vallota purpurea* sparingly for the next few weeks.

Prick off Herbaceous Calceolarias sown last month, into earthenware pans.

Continue to give established soft-wooded plants occasional applications of liquid manure.

Pot off seedlings of *Humea elegans* as soon as they are fit to handle.

Shift *Kochia trichophylla* into 6–7-inch pots as a final shift.

Prick off seedlings of *Rehmannia angulata Pink Perfection* into pans or boxes.

Give a second top-dressing to Liliums if the roots show on the surface.

Remove *Lilium longiflorum* to the backyard as it goes out of bloom, as it is useless for further decorative purposes.

Regulate the growth of climbing plants, where they hinder the admission of sufficient light.

Propagate Pelargoniums by cuttings, placing under a hand-light or in a close frame if this method be preferred to striking them outside.

Remove Hydrangeas to the open

air as they go out of bloom, and stand them in full sunshine to ripen the wood.

Discard any superfluous plants of Hydrangea, and remove the spent flower trusses of those retained.

Attend carefully to the watering of all plants, and continue to damp the pathways morning and afternoon in bright weather.

Continue to keep a sharp look-out for aphis or thrip, and vaporise if either is discovered.

Layer Malmaison Carnations in a close frame, but admit air when rooted.

HARDY FRUIT GARDEN.

Train in all Plum shoots required for extension, and stop the remainder.

Watch Plum trees for aphis, and spray on the first appearance.

Thin choice dessert Plums. Guard against dryness at the roots of the trees, or the fruits will fall.

Remove superfluous suckers from raspberry beds, retaining only a sufficient number of strong canes for next year's crop.

Hoe through raspberry beds regularly, and give liquid manure when watering. Mulch the beds afterwards. Net securely against birds.

Fasten the young shoots of Loganberries out of harm's way, tying these up permanently when the fruit is picked.

Remove side-shoots of Red Currants, but leave the main shoot for extension.

Give plenty of water and stimulants to Gooseberries on light soils. Renew mulching if necessary.

Bud fruit trees this month.

Continue to layer Strawberry runners for pot-work or early borders.

Thin early dessert Apples, giving these plenty of water at the roots on light shallow soils.

Water nectarine and peach borders regularly, applying artificials to trees bearing heavy crops, and mulch with rotten manure to conserve moisture.

Give late Strawberries copious supplies of water and liquid manure, to assist the later fruits to develop.

Destroy old strawberry beds as soon as the fruit is picked, to make room for other crops.

Cut off early Strawberry runners now rooted from the parent plant, and partially shade them for a few days. Plant out as soon as they have recovered from the check.

Layer late Strawberries, keeping the soil in pots moist to induce quick rooting.

Thin this year's growth on Blackberries and Loganberries. On light soils water well in dry weather.

Carefully net Gooseberries for late fruiting on cool borders, renewing the mulch if necessary.

Thin out finally all dessert Pears.

Water cordon Pear and Apple trees regularly, where growing in narrow borders.

Pick all soft fruits just before they are fully ripe.

Pinch the lateral growths on outdoor Vines closely, and expose the fruit to the sun as much as possible.

Spray Vines with insecticide two or three evenings in succession if mildew appears, and wash off with clean water.

See that the vine border does not lack moisture.

INDOOR FRUIT AND VEGETABLES.

Spray vacant Fig trees with liver of sulphur to prevent red spider.

Attend to pinching and thinning the shoots of Fig trees. Thin the second crop rather severely to ensure good ripe fruits.

Give a liberal amount of air to Melon plants in frames on sunny days, pinching the new shoots to prevent overcrowding. Keep the fruits off the soil.

Stand pot fruit trees that have finished bearing outside in a sunny position, and spray them with an insecticide.

Give Apple and Pear trees in pots frequent applications of weak liquid manure.

Syringe late Peach trees twice a day and water the border well if approaching dryness.

Give abundance of air on sunny days to Peach trees ripening their fruit, and allow a little top and bottom ventilation at nights.

Layer the strongest first runners of Strawberry plants into 3-inch pots, and keep the soil in a moist state until rooted.

Spray early Vines with liver of sulphur solution after completing gathering.

Pinch out the leading points of young Vines, when they have reached the top of the house. Pinch out the points of lateral growth beyond the first leaf.

Top-dress Cucumbers with equal parts loam, leaf-soil, and manure.

Pot June-sown Tomatoes into 3-inch pots, and keep them growing in a sunny airy position.

Top-dress the main crop of Tomatoes with rich soil. Pinch out side growths once a week, and shorten bottom leaves if a heavy crop of fruits are set.

Sow Parsley thinly in frames for a winter supply.

VEGETABLE GARDEN.

Pay strict attention to Cucumbers growing in frames. Give very frequent syringings, and when several fruits are set use either liquid manure or artificials freely.

Remove all flower stalks from Seakale. If this is done before the flowers open they make an excellent vegetable.

Weed and keep new asparagus beds well watered.

Sow a few rows of dwarf early Peas before July 10th, covering the seed deeper than is usual for earlier sowings.

Give maincrop Potatoes their final earthing up early in the month.

Spray Potatoes with Bordeaux or Burgundy mixtures twice during the present month allowing an interval of a fortnight between each spraying.

Keep Runner Beans showing flower buds well watered. Syringe the leaves after each hot day.

Bend over the tops of winter Onions as soon as these show signs of finishing their growth. Discontinue applications of stimulants after the first week of the month.

Keep the soil where Maize is growing always uniformly moist, feeding occasionally with liquid manure.

Plant winter greens of various sorts between the rows of second early potatoes, removing leaves here and there where these may give undue shade.

Keep Leeks intended for large specimens well supplied with manure water, and earth them up again.

Pay frequent attention to rows of Celery, dusting the leaves freely with soot and keeping the soil moist.

Give Celeriac plenty of water. Continue to plant for a late crop.

Sow more Shorthorn Carrots in light soil if the district is warm.

Sow a few short rows of Lettuce for autumn use, and hoe freely between plants now forming hearts.

Sow Endive during the present month. Batavian is preferable, as it is hardier.

Make a small sowing of Cabbage for spring use towards the end of the month, delaying the sowing for general crop until next month.

Watch outdoor Tomatoes, carefully removing all side-shoots and basal growths.

Feed Tomato plants carrying a heavy crop freely with liquid manure.

Lift all early Potatoes, selecting the tubers required for next season's planting, allowing them to remain on the ground for a few days.

Plant Cabbages on land vacated by second early Potatoes at the end of the month.

Sow Spinach Beet for autumn and winter use.

AUGUST.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Start layering Carnations without delay.

Bud more Roses.

Take more Rose cuttings.

Take further Geranium cuttings, inserting them out of doors in a sunny spot.

Complete pruning of hedges, etc., at once.

Disbud Michaelmas Daisies to improve bloom.

Disbud border Chrysanthemums.

Hasten the growth of winter bedding plants if this is slow, by applying soot water.

Continue feeding and watering all plants which appear to need it.

Start making preparations for winter bedding.

Dig over vacant land early.

Sow hardy annuals out of doors.

Re-make the reserve garden, discarding all summer bedding plants, which will not now be needed.

Remove flower-buds from any too forward winter bedding plants, otherwise they will be little use later.

Propagate various kinds of summer bedding plants by taking cuttings, inserting these out of doors.

Propagate Violas in the herbaceous border by cuttings.

Take cuttings of Fuchsias.

Plant at end of the month such subjects as Amaryllises and Colchicums.

Propagate more Pansies from cuttings thrown up early this month.

Propagate such plants as Hydrangeas, Ice Plants, Heliotrope, Petunias, Salvias, and Verbena, which now occupy the borders, by means of cuttings.

Water and feed all plants intended for autumn blooming, especially Sweet Peas and Roses.

Remove basal shoots and suckers of Roses before they grow to any size

Propagate many kinds of rock plants by cuttings or rosettes, especially Saxifrages, Sedums, and Sempervivums.

Plant out Brompton Stocks in a sheltered spot to give early bloom next year.

Prepare beds for planting Daffodils, Narcissi, and Tulips.

Look after shrubs, removing dead flowers.

Hoe shrubbery and other borders very frequently, removing weeds and stones.

Roll and mow lawns regularly.

Give garden paths a further watering of weed killer if wet weather immediately followed last month's dressing.

Weed lawns.

Trim grass verges to give a neat, smart appearance.

Plant out seedling Pansies to supply edging in place of those lifted last month for propagation purposes.

Start drying flower garden herbs, cutting them when in flower.

Make ready a place for this year's leaves, which will start falling before the end of the month.

Consider any forthcoming garden alterations and make plans fully now to save time later.

Overhaul colour borders, noting flowers with clashing colours and decide how to re-arrange them.

Prick out late sown winter bedding plants as early as possible and hasten their growth.

Be sure to have all plants securely tied up by the end of the month, for September is often windy.

Plant any kind of bulbs in the wild garden.

Continue all routine work conscientiously. If care is not taken now the borders may lose much of their grace and beauty.

Complete all work unavoidably held over from July as early as possible.

Leave for a fortnight's holiday early in the month, or you may have to do without a holiday this summer.

THE GREENHOUSE.

Propagate Zonal Geraniums by cuttings; insert the cuttings singly into 3-inch pots filled with sandy soil, and winter them in these pots.

Propagate *Aloysia citriodora*, *Eupatorium atrorubens*, *Fuchsia procumbens*, Heliotropes, Petunias, and *Trachelium caeruleum*, by cuttings, inserting in a close shaded frame.

Pot up Herbaceous Calceolarias into 3-inch pots towards the end of the month.

Pot up Cinerarias into 4-inch pots direct from the boxes into which the seedlings were pricked.

Examine Cinerarias for the Leaf Mining Weevil, and if present in small numbers, destroy by a gentle pressure of the leaf between the finger and thumb at the affected part.

Spray Cinerarias with a solution of quassia chips if badly infested with the above-mentioned pest, making sure that the under-sides of the leaves are thoroughly wetted.

Continue to give attention to the tying of Chrysanthemums.

"Take" the first crown bud of varieties of Chrysanthemums requiring this treatment.

Give Chrysanthemums a light top-dressing as soon as roots appear freely on the surface.

Apply liquid manure to Chrysanthemums as soon as the buds are "taken."

Propagate Cacti and other succulent plants early in the month, allowing the cut part to dry in the sun, prior to insertion in the soil.

Inure Hydrangeas and Pelargoniums to the air and light as the cuttings become rooted.

Pot up two-year-old Cyclamens which have been planted out in a pit or frame.

Sow Cyclamen thinly in a seed pan, which keep close and shaded until germination takes place.

Pot up Nile Lilies which were planted out, towards the end of the month.

Re-pot Nile Lilies, which were allowed to remain in their pots during the summer.

Remove all decaying matter promptly, also keep down weeds, and let cleanliness and tidiness be the order of the day.

HARDY FRUIT GARDEN.

Feed Fig trees bearing full crops regularly and give plenty of water.

Remove rank growth on Fig trees; train remainder very thinly, exposing the fruits to full sun.

Cut out old canes so soon as the Raspberry crop is picked.

Remove the nets from raspberry beds, label and store away for future use

Keep the young Raspberry canes thinned to a moderate number.

Pick the flowers off Perpetual Fruiting Strawberries for the last time, and keep the plants watered for late fruiting.

Thin Morello Cherries early for culinary use; train the shoots in carefully, but keep the fruit exposed. Net against birds. Give the trees plenty of water.

Expose Peaches and Nectarines to the sun as much as possible, to ensure fine flavour.

Give plenty of water to all fruits under glass copings.

Trap woodlice on fruit trees with the hollow stems of broad beans.

Top Gooseberry shoots for American gooseberry mildew, and spray the bushes afterwards.

Give late varieties of Apples, Nectarines, Peaches, Pears, and Plums their final thinning.

Give dessert Cherry trees a thorough washing with the garden engine after early fruit is picked.

Pinch all lateral growths on Nectarines and Peaches.

Clean up strawberry beds after the fruit is picked. Hoe them or fork them lightly over.

Prune Black Currants as soon as the crop is cleared off.

Clean Apricot trees as soon as the fruit is picked, and give an extra watering at the roots.

Look over and pick Nectarines and Peaches every few days. Gather just before they get fully ripe—especially for packing.

Train the necessary shoots on Plum trees for extension, and remove any not required.

Get nets off Gooseberry quarters, when the crop is over.

Water late Pears and pinch out all lateral growth on trained trees.

Keep all strawberry beds free from runners.

Stop and tie shoots on Fig trees.

Place muslin bags on ripening Figs if wasps are troublesome.

Prune early varieties of Peaches as soon as the fruit is picked, dispensing with as much of the old bearing wood as possible.

Protect ripe Morello Cherries on north walls from birds and wasps.

Place nets on fruits and hang up bottles of syrup as traps for flies and wasps.

Layer late varieties of Strawberries for planting next spring.

INDOOR FRUIT AND VEGETABLES.

Stand pot Fig trees in the sun outside to ripen the wood.

Keep a little fire-heat on in the Fig house during damp or dull weather and maintain a buoyant atmosphere.

Give Melon plants ripening their fruits a warm, airy atmosphere and keep the borders on the dry side.

Keep peach borders well watered, applying dressing of concentrated fertiliser to overcropped trees.

Defoliate late Peaches lightly in order that the fruit may colour well.

Pot Strawberry plants into 6-inch pots, standing the plants in a sunny position on ashes, and syringe them twice a day.

Give Muscat Grapes that are ripening a warm, airy atmosphere.

Renovate early vine borders.

Maintain a warm growing atmosphere in the Cucumber house, assisting the plants with weak manure water.

Sow seeds of Lettuce and Endive, and when large enough prick them off into frames.

Collect manure for mushroom beds and turn it three times a week.

Re-pot June-sown Tomato plants into 5-inch pots and keep them growing sturdily near the glass.

Give maincrop Tomatoes frequent applications of farmyard manure water.

VEGETABLE GARDEN.

Lift Shallots, if not done last month, and after thorough drying, store the bulbs in a cool shed.

Give transplanted Onions grown for large bulbs, a dressing of nitrate of soda early in the month, not more than two ounces to the square yard.

Avoid over-watering or over-feeding Tomatoes growing in the open air, or the fruits will split.

Gather fruits on all outdoor Tomatoes before fully ripe, finishing the ripening in a warm room or closed box.

Water outdoor crops as they need it with water which has been exposed to full sunshine for a few hours.

Keep Runner Beans well picked; even if only a few dozen pods are allowed to ripen the effect upon production is serious.

Keep late Peas well watered, or mildew may spoil the whole row.

Cut all Vegetable Marrows before the skins get too hard. Store those not used immediately in cool quarters for the winter.

Make the main sowing of spring Cabbage during the early part of the month.

Make a sowing of Red Pickling Cabbage this month, transplanting to permanent beds next spring.

Sow Lettuce early in the month to provide plants for filling cold frames for early winter use.

Make a final sowing of Parsley, selecting a nice sheltered spot.

Sow winter Spinach any time during the month, for heavy soil selecting the prickly seeded variety.

Remove all old worn-out leaves from rows of Spinach Beet, and give the bed a good soaking with fairly strong manure water.

Cut all Ridge Cucumbers before the points of the fruit turn yellow; store those not required, in a dark shed, with the ends in a saucer of water.

Continue to put out late varieties of Broccoli, giving the plants plenty of water until established.

Earth up early Celery and blanch by means of stout cardboard or brown paper.

Sow Turnips for winter use. The yellow flesh varieties have exceptional good keeping qualities.

Sow a little seed of one of the early varieties of Cauliflowers during the early part of the month.

Sow Onions for early use next year before 10th August. Consult seed lists for suitable varieties.

Pull up Peas as soon as they are over, sowing ground immediately with winter food.

SEPTEMBER.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Sow seeds of hardy annuals for producing early blooms next summer. Suitable sorts to include, among others, the following: — Agrostemma Coeli-rosa, Calendula Meteor, Calliopsis bicolor, Centaurea Cyanus (Cornflower), Clarkia elegans and pulchella, Collinsia bicolor and grandiflora, Eschscholzia, Eutoca, Flos Adonis, Godetia all varieties, Limnanthes, Linum, Lupinus, Malope, Nemophila insignis, Nigella hispanica, Poppy the Shirley, Saponaria calabrica, Silene pendula compacta, Virginian Stock (*Malcomia maritima*), and Viscaria oculata.

Clear away annuals from the flower borders as soon as they have finished blooming.

Cut down plants as soon as bloom ceases, or at least remove dead flower heads to prevent seeding.

Continue watering flower borders, the rock garden, etc., if weather is very hot.

Commence sweeping of leaves before the place becomes badly littered with them.

Discontinue all feeding of flowering plants early this month, as to continue would be to waste good material.

Discontinue the weekly mowing of lawns, greens, grass paths, etc., on 30th September.

Turn over heaps of rotted vegetable matter. The material will soon be wanted for digging in.

Cut out suckers from Roses and other climbers. These do much harm if left.

Cut back over rampant growth of any climbers (Roses, Clematis, Wistaria, etc. etc.) before the winter, and tie in all long shoots firmly before the gales come.

Obtain a further supply of Rose cuttings if those put in earlier have died.

Continue to propagate the host of bedding plants, inserting the cuttings this month in frames.

Commence taking cuttings of Alyssum, Calceolarias, and Pentstemons. August is too early for this work.

Take more cuttings of Pansies and Vio as from the herbaceous border or reserve garden to ensure an ample supply next year.

Sever Carnation layers and re-plant them in their permanent positions.

Push forward plans for structural alterations, and have all materials in readiness.

Commence to propagate shrubs again by cuttings inserted firmly in a deep nick made with the spade.

Propagate herbaceous perennials by

means of cuttings which are now freely thrown up.

Stake and securely tie-in such plants as Chrysanthemums, Dahlias, Hollyhocks, Michaelmas Daisies, Sunflowers, and tall Thalictrums, otherwise they may easily be broken by being blown over.

Protect all flowering plants from pests, especially from earwigs, which are very troublesome just now.

Plant Polyanthuses into their flowering positions.

Plant out Pink pipings in their permanent positions, or transfer them to a cold frame.

Continue disbudding flowering plants if extra choice late flowers are desired.

Continue all routine work religiously.

Make great efforts to prolong the beauty of the garden as long as possible by looking well after all plants at this trying period.

Cut flowers regularly and frequently. The more you cut the more you will get if the autumn is open.

Stir the surface of flower borders and shrubberies every week to prevent autumn weeds getting a hold.

Make a list of flowering plants, climbers, perennials, bulbs, etc., you will require, and order them early.

Take a final scrutiny of your colour borders in case there are early frosts next month, making notes for future use.

Complete all flower garden work unavoidably held over from August as early as possible.

THE GREENHOUSE.

Pot Italian and Roman Hyacinths, three bulbs in a 5-inch pot, and plunge in sandy soil or ashes.

Pot and plunge Daffodils, especially such serviceable varieties as Emperor, Empress, and Golden Spur.

Pot and plunge such Narcissi as Paper White, Poeticus, and Poeticus ornatus.

Pot Chionodoxas, Crocuses, Freesias, and Scillas.

Cut down Pelargoniums early in the month, and place in a cold pit or frame to "break." Syringe them daily in the afternoon.

Sow Clarkias and Schizanthuses in pans or boxes early in the month, and place in a cold frame.

Sow Machet Mignonette in 5-inch pots and place in a cold frame, for winter blooming.

Sow Sweet Peas in 3-inch pots, for indoor culture.

Propagate Fuchsias by cuttings in a close frame.

Propagate *Crassula coccinea* in pots of sandy loam in a well-ventilated frame.

Continue to "take" the buds of big-bloom Chrysanthemums.

Disbud bush Chrysanthemums as soon as the work can be done without damaging the buds.

Allow the small-flowered varieties of Chrysanthemums—such as Kitty Bourne—to develop naturally.

Keep a sharp look-out for aphis and the leaf mining weevil on Cinerarias, and if present apply the remedies previously recommended.

Remove the glass cover from Cyclamens as the seedlings appear.

Thin out Mignonette in pots towards the end of the month.

Pot off seedling Clarkias and Schizanthuses towards the end of the month.

Re-pot Pelargoniums as soon as they have started into fresh growth. Use pots a size smaller than those the plants flowered in.

Attend to all necessary repairs both outside and inside the house, painting the house outside or inside if necessary.

Wash the glass and woodwork, prior to arranging the plants for the winter.

Bring in winter-flowering Geraniums, and give them a light airy position.

Bring in the entire stock of Carnations and *Salvia splendens*. Continue to feed the latter until they begin to show colour.

Collect seed of tuberous-rooted Begonias.

Withhold water from Liliums by degrees.

Discontinue shading after the middle of the month.

Surface dress all hard-wooded plants, and wash their pots.

Bring in all hard-wooded plants during the last week of the month, and group them together as far as practicable.

Bring in *Vallota purpurea*.

See that the heating apparatus is in good working order.

Reduce the ventilation on cold nights.

HARDY FRUIT GARDEN.

Mark fruit trees which are not bearing but making vigorous growth, for root-pruning.

Plant main beds of Strawberries on well-prepared ground.

Thin dessert Plums severely; give plenty of water, and renew mulching if necessary.

Examine budded stocks and loosen ties if too tight.

Mark all inferior or worn-out fruit bushes for destruction later.

Whitewash and thoroughly cleanse the fruit room, in readiness for fruit storing.

Prepare composts in readiness for planting and top-dressing later.

Prune off all superfluous growth on Apples and Pears and expose the fruits to the sun.

Remove suckers from the base of Cobnuts and Filberts.

Gather early Apples and Pears for immediate consumption. Do not attempt to store these.

Prepare stations for planting fruit trees.

Transplant early Nectarines and Peaches which have completed their growth this month. Make them firm.

Keep a sharp look-out on ripening fruit, and pick on fine days.

Deeply trench and heavily manure ground for new raspberry plantations.

Commence root-pruning if weather is not too hot and dry.

Water transplanted trees, and syringe overhead on warm afternoons.

Place all orders for fruit trees with the nurseryman in good time. Late comers get the leavings.

Cut out all old fruiting canes from Loganberries and train or tie the young canes into their permanent positions.

Put spare lights in front of late Peaches to ripen up the fruits.

Destroy all wasps' nests, with potassium cyanide.

Get all preparations for extensive fruit planting forward.

Give plenty of water to trees under glass copings if weather is dry.

Cut off all superfluous growth on Figs, and root-prune if growth is gross. Avoid rich soil when planting.

Pick Mulberries for bottling.

Exposé grapes on outdoor Vines to the sun as much as possible to ripen them thoroughly.

INDOOR FRUIT AND VEGETABLES.

Apply soakings of liquid manure to Fig trees that have borne heavy crops.

Maintain a night temperature of 75° F. for Melons. Damp the house down on sunny days and discontinue syringing.

Stand pot fruit trees in a sunny position outside.

Give all the air possible to Peach trees night and day.

Dip Strawberry plants in soap and liver of sulphur solution.

Cut out all lateral growth of early Vines. Keep ventilators wide open night and day, with heat turned off.

Keep a little heat and air on constantly for Vines carrying ripe fruit.

Maintain a minimum temperature of 75° F. for Cucumbers.

Make up mushroom beds in warm dark sheds.

Re-pot Tomato plants for winter cropping into 10-inch pots, and tap the supports daily to ensure pollination of the fruits. Keep a little fire heat on for the main crop, and grow the plants under drier conditions at this season.

VEGETABLE GARDEN.

Bend over the tops of Onions grown for large bulbs, and as soon as these are withered, carefully lift the bulbs and complete the ripening in a warm house.

Lift maincrop Onions early in the month and lay out thinly on sacks or in boxes to get fully ripened previous to storing in winter quarters.

Continue to gather Dwarf or Runner Beans before the pods get stringy. Give liberal supplies of water to any rows still in flower.

Reduce the foliage on outdoor Tomatoes early in the month, exposing the fruit to the full sun. Give the plants liberal supplies of liquid manure.

Cut away many of the extra large leaves upon the Vegetable Marrows or Ridge Cucumbers in order that the latest formed fruits may have the benefit of full sunshine.

Give the latest sown rows of Dwarf Beans a little protection, if early frosts threaten.

Get the bed of spring Cabbage planted as early in the month as the plants can be conveniently handled.

Pot up seedling Cauliflowers from seed sown last month, and stand the pots on a bed of ashes in a cold frame.

Thin out rows of Turnips and Spinach sown last month and encourage the plants to make rapid progress by the free use of the hoe.

Give maincrop Celery copious supplies of water throughout the month, earthing up the early runs again.

Plant out a good batch of Endive in a sheltered border.

Lift and store maincrop Potatoes towards the end of the month.

Lift Beetroot carefully with a fork, and after twisting off the tops, put in clamps or store in a cool shed.

Give Leeks an abundance of liquid manure, well earthing up again those required for early use.

Sow a little Corn Salad in a warm border early in the month, to provide a late autumn supply.

Gather good-sized bunches of all the more popular potherbs, and when thoroughly dry hang these in a shed free from dust, or better still place in muslin bags.

Give plenty of air to young Carrots growing in frames throughout the month.

Lift and store the main crop of Carrots, storing between layers of dry soil or sand.

Give backward plants of Lettuce a watering with a half-ounce of nitrate of soda to each gallon of water.

Give Cauliflowers which promise to be late in forming heads plenty of liquid manure.

Lift and store Salsafy sown extra early which seems inclined to go to seed.

OCTOBER.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Take up summer bedding plants immediately this month starts. Destroy them, or pot them on for greenhouse use.

Clear away all hardy annuals sown last spring early during the month if winter bedding is to be put down.

Dig and manure beds which have had summer bedding plants in them.

Plant all kinds of winter bedding stuff, *Alyssum saxatile, Arabis albida,* Canterbury Bells, Myosotis, Polyanthuses, Sweet Williams, Wallflowers, etc.

Plant all kinds of bulbs, in the borders, in the rock garden, in the grass (dwarf sorts such as Aconites, Crocuses, Scillas, Snowdrops, etc.), and in the wild garden.

Plant all kinds of spring colour beds. Tulips make some of the best subjects for this work.

Plant any of the following among other subjects in the rock garden :—Æthionema, Alyssum, Anchusa (dwarf), Androsace, Anemone (dwarf), Antennaria, Arenaria, *Aster alpinus,* Aubrietia, Campanula (dwarf), Crucianella, Dianthus, Dryas, Gentiana, Helianthemum, Hepatica, Iberis, Lithospermum, Onosma, Phlox (alpine varieties), Primula, Saxifraga (all varieties), Sedum, Sempervivum, Silene, and Veronica (dwarf sp.).

Cut down perennial plants as soon as they go out of bloom, clearing away the refuse.

Continue to cut the flowers of plants still in bloom as freely as possible with a view to getting further flowers.

Make a start on all kinds of structural alterations, making new paths, building garden steps, erecting poles, pergolas, arbours, and arches, and so on.

Complete the plans for further structural alterations, and get materials ready for carrying them out.

Sweep up leaves which now fall rapidly, regularly twice a week, or the place is apt to become a wilderness with the litter they make.

Insert further supply of Calceolaria, Pentstemon, and Alyssum cuttings if those inserted last month have damped off.

Roll paths, drives, and lawns regularly once a week, preferably after well brushing them.

Cut down Dahlias and lift the roots, storing in a frost-proof shed.

Lift small seedling perennials from reserve beds as soon as the weather turns cold, and put them into a frame.

Avoid mulching rose-beds at this time of the year, as the manure may damage the roots.

Apply basic slag to lawns and greens at the rate of 4 oz. per square yard.

Apply Tonk's manure to rose-beds unless you prefer to use this formula in the spring.

Trench land intended for autumn planting of perennials as early in the month as possible.

Tie up all late flowering plants, Chrysanthemums, Sunflowers, etc. etc., for they may bloom till 31st October.

Top-dress pockets in the rock garden with fine soil. Put pieces of glass over choice Androsaces, etc., to throw the rain off them.

Remove dead flowers, leaves, and other rubbish from the rock garden. Renew labels in it.

Buy and plant new Roses and other climbers.

Buy turf for renovating bare patches on the lawn.

Lift all tender plants propagated out in the open, putting them in heated houses or frames for the winter.

Plant out permanently a further stock of layered Carnations, protecting them from slugs by rings of zinc.

Prepare sites for new shrubberies.

Go through your garden notes, correlating details together to serve as a guide for future alterations.

Continue all routine work unceasingly to give the garden a bright and neat appearance.

Complete all September work proper, as early as possible during the present month. Delays are dangerous, for the weather may break up at any time and make outside work impossible.

THE GREENHOUSE.

Prune pot Roses, and rectify the drainage if deranged, prior to standing them in a frame.

Stow away Cannas, Crinums, Fuchsias, and Liliums on their sides under the staging, or in a frost-proof shed.

Stand Deutzias and Philadelphuses in a frame.

Bring in Calceolarias, Clarkias, Mignonette, Schizanthuses, and Sweet Peas, and place them on shelves near the glass.

Pot up Hyacinths, *Iris reticulata*, Sparaxises, and Tulips, and plunge in sand.

Pot Astilbes, *Azalea mollis*, and Lilacs as they come to hand, and stand in a frame.

Continue to disbud bush Chrysanthemums omitting the small-flowered varieties.

Spray all Chrysanthemums with a solution of potassium sulphide as a preventive of mildew.

Pick off all decayed foliage on Chrysanthemums and wash the pots.

Bring all the Chrysanthemums indoors by the middle of the month, beginning with the big bloom varieties.

Give Chrysanthemums bi-weekly applications of liquid manure until the flowers show colour.

Disbud Perpetual Flowering Carnations.

Pinch Mignonette when 2 ins. high.

Pinch Clarkias, Schizanthuses, and Sweet Peas when 4 ins. high.

Pot on young Pelargoniums as they fill the small pots with roots.

Pot up *Lilium longiflorum* and *L. longiflorum eximium* (*Harrisii*), allowing one bulb to a 6-inch pot.

Shake out tuberous-rooted Begonias, arrange the tubers, crown upwards, on a shallow tray, and store in a cool, dry frost-proof room.

Fumigate or vaporise the house as soon as the various soft-wooded subjects have been brought in.

Apply water with great care from now onwards, distinguishing between plants in active growth and those comparatively at rest.

Attend to watering early in the day, and be careful not to spill water about the house.

Ventilate as freely as the state of the weather will permit, leaving a little air on overnight unless frost occurs.

Apply a little fire-heat if frost occurs, or to dispel damp should the weather prove foggy.

Remove all decayed flowers and foliage promptly.

Shift Cinerarias into their flowering pots.

Get a good supply of potting materials under cover for winter use.

HARDY FRUIT GARDEN.

Use the garden engine on wall-trees after fruit is picked if insects are troublesome.

Use plenty of lime when planting or root-pruning stone-fruits.

Fork over the soil between fruit bushes after treading down during fruit picking.

Commence winter pruning any time after growth has ceased.

Renovate fruit borders where old trees are showing signs of exhaustion, and replace worn-out soil with a rich compost.

Store late varieties of both Apples and Pears after they are thoroughly ripened.

Put grease bands on orchard trees early this month.

Fill up all vacant spaces on fruit walls with young trees.

Remove superfluous leaves on Peach trees, to assist the thorough ripening of the wood.

Pick Cobnuts and Filberts on a dry day, and store in a cool cellar.

Plant Raspberries in well-prepared ground.

Prune fruit-bushes early, so that the

bushes have the benefit of full exposure.

Give liberal treatment to fruit-bearing trees when top-dressing.

Plant fruit trees and make very firm.

Secure newly planted trees to stakes without delay.

Partially lift and root-prune all Peach trees making extra strong growth and amend errors in drainage.

INDOOR FRUIT AND VEGETABLES.

Syringe early permanent Fig trees after second crop is gathered until the leaves fall.

Give ripening Figs a warm airy atmosphere.

Prune and put in shape all pot fruit trees.

Re-pot pot fruit trees, in good fibrous loam, adding bonemeal, lime rubble, and wood ashes. Plunge the pots up to the rims in ashes in a sheltered position outdoors.

Prune early Peach trees, aiming at an even distribution of this year's growth.

Renovate early peach borders with a good dressing of bonemeal and fresh loam.

Spray Peach trees when all leaves have fallen with a caustic alkali wash.

Remove Strawberry plants in pots to good light frames. Give plenty of air except in very frosty weather. Water carefully and avoid excessive moisture.

Cut back the main shoots of early Vines half their length, and in two or three weeks' time prune to a prominent bud at two or three eyes from the base. Cleanse the house thoroughly, and wash the Vine rods with a strong solution of an insecticide. Top-dress the borders with an approved Vine manure and bonemeal, adding a layer of fresh loam.

Cut out the sub-lateral growth of late Vines to allow both fruit and wood the full benefit of sun heat. Examine bunches weekly for decaying berries.

Plant Lettuce and Endive in frames and admit plenty of air.

Damp the Mushroom house down daily, and avoid overheating. Make a second bed for succession.

Put the lights on Parsley frames and keep well ventilated.

Pack Potato sets in single layers in boxes to sprout for early forcing, and place them under the greenhouse stage.

Lift Rhubarb roots for forcing, and leave them exposed on the surface for two or three weeks.

☞ Maintain a warm, dry atmosphere for Tomatoes. Top-dress the plants as the roots show on the surface, and sow seeds for early crop.

VEGETABLE GARDEN.

Protect Cauliflowers sown in August from early frosts.

Fill an empty frame with good plants of Parsley, taking care to lift this with plenty of soil on its roots. Lift half-grown Lettuces standing in exposed quarters, re-planting where protection can be given should unfavourable weather threaten.

Lift and protect a few Endive plants at this season, where a constant supply is valued all the winter.

Take care of all Cauliflowers or Broccoli now forming large heads. Prior to frost carefully lift with a fork and stand in a cool shed or cellar.

Remove all foliage from Asparagus as soon as this is quite brown. Clear the bed of weeds.

Gather all well-developed fruits on outdoor Tomatoes at once. Do not risk leaving them after the middle of the month.

Stand fruit of Tomatoes on sunny greenhouse shelves to ripen and make small green fruit into chutney.

Cover plants of Vegetable Marrows, which are still carrying numerous small fruits, with a garden frame, or a little hay or straw.

Use the hoe freely among all growing crops, especially late green Spinach or Turnips.

Give Brussels Sprouts plenty of liquid manure if they are late in forming "buttons." Avoid cutting the top leaves off.

Clear away all decaying leaves from Cabbages and similar crops, and use the hoe between the rows.

Protect the crowns of Globe Artichokes by heaping ashes over them about the end of the month.

Place a stick to all likely clumps of Rhubarb as a guide when selecting these next month for forcing.

Collect fresh fallen leaves from Oak, Elm, or Beech trees and store in a dry corner.

Start retarded crowns of Seakale in heat this month. Remove large leaves from beds in the garden and take off all likely crowns for removal to forcing pits or houses in December.

Keep the rows of Onions sown in August quite free from weeds, but do not attempt to force growth at this stage.

Look carefully over the store of large

Onions put under cover last month, removing all showing signs of decay.

Sow large growing varieties of Onions in shallow boxes and place in a cold frame all the winter. Give plenty of air when outside conditions are favourable.

Lift further batches of Carrots, Parsnips, and Salsafy, storing in sand.

Complete the lifting of late main-crop Potatoes immediately.

Make up Potato clamps.

Lift the first batch of Jerusalem Artichoke tubers after cutting down the growth.

Harvest and store all roots of Cardoons and Celeriac. Garden Swedes and Kohl Rabi can be left to stand the winter and be pulled as required.

NOVEMBER.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Work hard at structural alterations on all suitable days until they are completed. Structural alterations which should now be done include—

(1) Making of New Borders.
(2) Laying of New Lawns.
(3) Making of New Shrubberies.
(4) Making of New Paths.
(5) Making of special gardens, as, for instance Rock Gardens, Japanese Gardens, Wild Gardens, Water Gardens, Herb Gardens, etc.
(6) Erecting New Garden Terraces.
(7) Erecting New Garden Steps.
(8) Erecting New Arches, Rose Poles, Pergolas for climbers, Arbours for trailing plants, etc.
(9) Erecting of New Garden Summer-house.
(10) Removing of paths, existing steps, etc. etc.

Continue pushing forward floral alterations, such as—

(1) Re-arranging borders of plants according to their height.
(2) Re-arranging borders according to the colour of the flowers.
(3) Re-arranging borders so that each contains plants of one habit only, *i.e.* tall plants only, dwarf plants only, sweet-smelling plants only, or plants for cutting only.
(4) Making of direct colour borders.

Plant all kinds of herbaceous perennials.

Plant all kinds of hardy bulbs, completing this work by 7th November.

Plant all kinds of biennials for winter bedding, but complete this work as soon as possible.

Apply naphthalene to vacant flower garden land, to kill any lurking pests.

Apply lime to the new borders before planting.

Protect less hardy perennial plants in the borders by heaping ashes or fibre over their crowns.

Securely fasten growths of newly planted climbers to trellis or wall.

Lift early flowering Chrysanthemums and store the roots in a cold frame.

Protect Helleborus plants from cold and wet.

Keep beds of late blooming plants scrupulously tidy. Don't forget that neatly trimmed grass edges add much to the general appearance.

Plant all kinds of rock plants.

Plant all kinds of wall garden plants.

Plant all kinds of wild garden plants.

Plant all kinds of water garden plants.

Plant the following or any other trees and shrubs: Alder, Ash, Araucaria, Azalea, Beech, Birch, Blackthorn, Chestnut, Elm, Fir, Hawthorn, Holly, Laburnum, Larch, Laurel, Lime, Lilac, Oak, Pine, Plane, Poplar, Privet, Rhododendron, Sycamore, Walnut, Willow, and Yew.

Plant any or all of the following evergreen shrubs: Aucuba, Berberis, Buxus, Cerasus, Cotoneaster, Ilex, Laurus, Ligustrum, Ruscus, Spartium, Ulex, Viburnum, etc.

Plant any or all of the following deciduous shrubs: Buddleia, Chimonanthus, Cornus, Deutzia, Euonymus, Genista, Hibiscus, Kerria, Philadelphus, Ribes, Rubus, Spiraea, Syringa, etc.

Plant Roses.

Plant hardy climbers.

Dig over vacant land.

Spread a little rotted manure on the surface of existing perennial borders, forking it in immediately.

Apply basic slag if this has not already been done.

Complete all October work as early in November as is conveniently possible. Use all fine days for out-

door flower garden work, for indoor work can be done on wet days.

THE GREENHOUSE.

Bring in the first batch of Roman Hyacinths and Paper White Narcissus from the "plunge," at the beginning of the month.

Take cuttings of big bloom varieties of Chrysanthemums as they become available.

Reduce the supply of water to any Chrysanthemums whose blooms show signs of damping.

Pot up *Dielytra spectabilis* and Lily of the Valley, choosing strong crowns of the latter.

Pot on Herbaceous Calceolarias into 5-inch pots, using a rich flaky compost.

Consult the Chrysanthemum specialists' lists, or if convenient, visit one such establishment, with a view to the purchase of desirable novelties.

Renew the labels of permanent subjects where necessary.

Bring in the second batch of Paper White Narcissus and Roman Hyacinths; also a batch of the little-known Italian Hyacinths, at the end of the month.

Give careful attention to ventilation, admitting air early in the day on all favourable occasions.

Maintain a minimum night temperature of 45° F., where Perpetual Flowering Carnations are grown.

Poison or trap mice if they attack Carnations.

Wash all empty pots and seed-pans and stow away on the pot-rack.

Wash all crocks intended for drainage, and thereafter grade them into two sizes by passing them through a ¾-inch sieve.

Select curved crocks for placing over the drainage hole, and grade them into three sizes.

Cut and stack sufficient turf from an old pasture for next season's requirements.

Procure and place under cover a sufficient stock of cow or horse dung, and sharp clean sand.

Collect and stack leaves for forming leaf-mould for future use. Oak leaves have the highest value, and those of the Beech come in second.

HARDY FRUIT GARDEN.

Plant Gooseberry bushes on ground that has been deeply trenched and well manured a few weeks previously.

Push on the pruning of all kinds of fruit trees during fine weather.

Wheel out manure to fruit quarters on frosty mornings.

Dig between fruit trees and bushes after the pruning is finished.

Prune Morello Cherries. Cut out all old fruiting wood that can be spared, retaining sufficient of the ripened shoots to furnish the allotted space.

Plant Raspberries on well-prepared ground. Use plenty of manure and bonemeal when preparing for them.

Plant dessert Cherries on walls, and use plenty of lime rubble in the compost.

Finish root-pruning this month if possible.

Clear out old decayed trees from orchards, grubbing up all the roots.

Protect Fig trees in cold districts with dry bracken fern or mats.

Continue to prune and train all wall fruit trees.

Propagate all bush fruits by cuttings.

Top-dress fruit trees in narrow borders, using a rich compost for bearing trees.

Avoid using fresh manure when planting Apples, Damsons, Nectarines, Peaches, Pears, and Plums.

INDOOR FRUIT AND VEGETABLES.

Cleanse Fig houses, and wash trees with an insecticide after necessary cutting out of weak or overcrowded shoots has been completed. Top-dress the borders with loam and bonemeal after removing loose surface soil.

Spray pot fruit trees with a good caustic alkali wash.

Prune late Peach trees, and plant young ones.

Cut and store late Grapes.

Prune mid-season Vines after they have shed their leaves.

Water Endive and Lettuce very carefully. Remove decaying leaves and ventilate freely.

Maintain as near as possible a temperature of 50° F., in the Mushroom house.

Lift Seakale roots, and store them in a bed of ashes in the open.

Plant Rhubarb roots in Mushroom house or under greenhouse stage and keep dark.

Keep young seedling Tomatoes growing on a shelf near the roof glass in a temperature of 55–60° F.

VEGETABLE GARDEN.

Give the late rows of Celery the final earthing up, first making sure the soil at the roots is in a moist condition and that the leaves are quite dry.

Plant more Colewort, or London Greens, a foot apart for use during the early months of the next year.

Sow a few rows of Longpod Broad Beans, in a sheltered border where manure has been freely used.

Pick the rows of Spinach with care; whenever possible confine attention to a single row at a time.

Sow round-seeded varieties of Peas this month, more thickly than is usual, especially where the soil is heavy and insects numerous.

Suspend ripe Marrows intended for winter use from the roof of an airy shed.

Give late-planted Leeks plenty of liquid manure between the rows, delaying the final earthing up until next month.

Lift a few Parsnips and store in a cool shed as a reserve against bad weather if the district is an exposed one.

Keep a good supply of dry straw or bracken on hand for covering beds of Endive or Spinach should exceptional frost threaten.

Continue to collect dry leaves for making compost.

Dig, trench, or ridge all land as soon as this becomes vacant.

Continue lifting tuberous and tap-rooted crops.

DECEMBER.

OUTDOOR FLOWER GARDEN AND PLEASURE GROUNDS.

Plant shrubs and trees when weather is open.

Continue planting hardy herbaceous plants, rock plants, the wild garden, the water garden, etc., on fine days.

Renovate lawns, renewing the turf when necessary.

Roll walks, drives, lawns, gravel, tennis courts, etc., very frequently.

Sweep up the last of the leaves and make them into vegetable mould.

Tidy up all flower borders early in the month, cutting down the last plants which have bloomed.

Fork over all herbaceous borders, working in manure if not already done.

Renew labels where needed to rock plants and herbaceous perennials.

Continue planting Roses and hardy climbers.

Continue every kind of structural and general alteration of the garden except in frosty weather.

Tread the ground round newly planted herbaceous plants after frost to give them a firm root-run.

Put pea-sticks to support mats over annuals in very cold weather to keep them alive.

Insert more shrub cuttings.

Complete the winter bedding if owing to pressure of other work this could not be done last month.

Remove snow from choice specimen trees, bushes, climbers, etc., if there is so much that it may break their branches.

Renovate garden paths and drives.

Re-set edging stones to borders if inclined to sink.

Re-plant edging subjects if they have grown too thick.

Rake over shrubberies and remove leaves.

Fork over ground between shrubs working in some manure and peat.

Drain any portions of the garden which are too damp.

Prepare labels for spring planting.

Make plans for next year's work.

Go through your garden notes for this year to summarise your work.

Peruse seed catalogues as soon as they arrive.

Write your order for spring seeds and spring plants and send it in as soon as possible.

Re-make the reserve garden, since this will be vacant at the present time of the year. Dig and manure it thoroughly.

Fork over rose-beds if this has not been done.

Protect any plants which may be starting to bloom, from sudden bad weather.

Loosen the soil slightly round early bulbs which may be appearing.

Plant new hedges.

Grub out old shrubs which have become dilapidated during the year.

Make an effort to start the New Year well with work done up to date and as it should be.

Look over the rock garden, and see that the glass protecting Androsaces, etc., is still in its place.

Re-set any rock stones which may

have become loose owing to wet weather.

Ridge and trench all vacant land in the flower garden, manuring at the same time.

Pay some attention on dark December days to the Literature of the Garden. Read our article on this subject.

Make yourself a successful and proficient gardener by studying the cultural articles given in this Dictionary: they will help you.

Finally make a resolution to gain more success in the New Year than you have done in this one.

THE GREENHOUSE.

Propagate Chrysanthemums of the big bloom type, by cuttings.

Cut down big bloom Chrysanthemums, and remove them as soon as sufficient cuttings have been secured.

Cut down bush Chrysanthemums as they go out of bloom, but defer the propagation of these.

Introduce Chionodoxas, Daffodils, and Hyacinths, also Tulips of the Duc Van Thol type.

Pinch Schizanthuses when they have made 3 ins. of fresh growth.

Furnish Schizanthuses with temporary dwarf stakes.

Sponge the foliage of Agaves, Cordylines, Dracænas, and other smooth-leaved plants requiring cleaning.

Top-dress or, if necessary, re-pot *Cypripedium insigne*, finishing off with a layer of sphagnum.

Examine established Fuchsias stored away, and apply water if necessary. They should not be allowed to become dust dry.

Examine Begonia tubers lest they should suffer from damp, or from the attacks of mice.

Examine Lapagerias, and, if infested with brown or white scale, remove the pests with a pointed stick, and thereafter sponge with a solution of soft soap and tepid water.

Give Cinerarias weekly applications of liquid manure.

Continue to exercise great care in watering, as any excess at this season will have disastrous results.

Remove spent blooms, decayed leaves, and all decayed matter promptly.

Ventilate the house daily in moderation, if the external temperature does not fall below 40° F.

Maintain a buoyant atmosphere by warming up the pipes occasionally with the ventilators partially opened.

HARDY FRUIT GARDEN.

Postpone planting of fruit trees when the soil is wet or sticky.

Trench ground for spring fruit planting.

Keep the heads of standard Apple trees thoroughly open in the centre when pruning.

Plant Damsons on the outsides of orchard to break the wind.

Mulch all newly planted fruit trees with light manure.

Fork over strawberry beds, burying the seedling weeds.

Burn all perennial weeds with fruit tree prunings.

Plant Black Currants in a moist and partially shaded border.

Transplant one and two year old fruit bushes, giving them double the room.

Proceed with spraying after pruning orchard trees.

Prepare various composts for top-dressing fruit borders.

Prepare labels, stakes, and shreds in bad weather.

Use lime or lime rubble when planting all stone fruits.

Protect the stems of fruit trees in exposed situations from rabbits.

INDOOR FRUIT AND VEGETABLES.

Commence to force Figs in pots in a temperature of 50° F. Syringe the trees on sunny days. Water carefully until growth is active.

Cleanse late Peach houses.

Start early Peach trees in pots in a temperature of 45–50° F.

Start the early vinery towards the end of the month in a temperature of 50° F.

Prune late Vines.

Cleanse mid-season and late vineries.

Sow the first batch of Dwarf Bean seeds in boxes in a temperature of 55–60° F.

Blanch Endive by keeping the frame dark and protected from frost.

Pot up Seakale in a warm greenhouse for early forcing.

Introduce Rhubarb roots for forcing every three weeks throughout the winter and keep well watered after growth has started.

Water Tomato plants with care and give a little air on sunny days.

VEGETABLE GARDEN.

Continue to clear away all garden rubbish, burning all that is not decay-

able. Store the dry ashes in wooden boxes for use when sowing seed in spring.

Dig up strong clumps or single crowns of Rhubarb early in the month, planting them close together in boxes and placing in a warm house.

Introduce the first batch of home-grown Seakale into heat, selecting the strongest crowns.

Commence forcing Chicory from now onward where absolute darkness can be secured.

Trench land intended for any deep-rooting crop next season, using plenty of rich manure in the bottom spit.

Give constant attention to salads, or Cauliflowers growing in cold frames. Remove all decaying leaves, and give ventilation when conditions are favourable.

Tread the soil between the rows of Cabbages planted early in the autumn to firm the soil round them after frost.

Protect Cauliflowers or Broccoli from frost, by placing a sheet of paper or spare leaf over the heads now forming.

Look over the store of all vegetables very frequently; avoid a stuffy atmosphere which induces early decay.

Start forcing three or four year old Asparagus in a warm house or upon a gentle hotbed.

Complete the lifting of root crops.
